MESSAGE

It is a matter of great pleasure that National Conference on 'Wildlife Health Management vis-à-vis Prospect of Mitigation of Extrinsic Influences Impinging their Conservation' is being organised at College of Veterinary and Animal Sciences, G.B. Pant University of Agriculture & Technology, Pantnagar, U.S. Nagar, Uttarakhand on 29-30 September, 2018 in collaboration with Association of Indian Zoo and Wildlife Veterinarians.

Expansion of human needs as well as greeds resulting in encroachments of forest lands and wildlife territories in various states of the country is frequently leading to conflicts between human and wild animals. The unprecedented impetus to urbanization is posing further threats to wild flora and fauna culminating into severe damage to the delicate ecosystem and overall biodiversity.

It is expected that scientific deliberations amongst academicians, wildlife experts, business organizations and other delegates would result in sound recommendations that will help in deceleration of extinction of various wildlife species in the country and strengthen preservation of our rich biodiversity.

I extend my warm greetings to all the participants and wish the conference a grand success.

(T. MOHAPATRA)

MESSAGE

It gives me pleasure to know that 2nd International Conference on “**Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)**” is going to be organised by Agriculture Technology Development Society (ATDS), Muradnagar, Ghaziabad (U.P.) during October 20-22, 2018.

Advance innovations in Agricultural, Biological and Applied Science help the policy matters address the problems more effectively relating to Food Security, Medicine and Environmental Sustainability. I hope the deliberations in the conference shall dwell on various dimensions in these important areas so as to open up new vistas of research for the guidance of policy planners.

I convey my good wishes to the organisers for the grand success of the Conference.

MESSAGE

I am happy to know that Agriculture Technology Development Society (ATDS) Ghaziabad, in collaboration with Swami Vivekanand Subharti University, Meerut (U.P.) India and faculty of Agriculture, Cairo University, Egypt is going to organize 2nd International Conference on “**Advances in Agriculture, Biological and Applied Sciences for Sustainable Future**” (ABAS 2018) on October 20-22 at Sardar Patel Auditorium Swami Vivekanand Subharti University, Meerut (U.P.) India.

As we know that food is basic need for survival of human being and it became vital once its availability is adequate to quench the world population. Toward achieving the goal of livelihood security it is important to conserve the agriculture. I hope that this conference will create an opportunity for the researchers, academicians to gain new ideas and understand the recent advances in agriculture, biological, applied science and conservation of biodiversity for sustainable future. I am sure that scientific/ technical deliberation and discussion will be greatly benefited to the delegates, participants and policy makers. Moreover it will also help in solving different problem and issues.

I convey my blessing and good wishes for the success of this 2nd International Conference and compliment to the organizers.

MESSAGE

With rapidly increasing population, achieving the sustainable food and nutritional security and overcoming regional imbalances across the globe is major challenge of the human society in 21st century. The shrinking natural resources, whether uncertainties due to climate change are the major threats to achieve a sustainable food security in the world especially in developing and underdeveloped countries. According some estimates agricultural production need to be increased by 70 percent from 2005-2050 to feed an estimated population of 9.1 billion.

It will be indeed difficult to meet these daunting challenges only with the application of conventional techniques and tools, as no headway is being made through these approaches. The scientific and technological advancements and their application in the field of agriculture is the key to address the emerging challenges.

I perceive that Advances in Agricultural, Biological and applied sciences for sustainable future (ABAS-2018) organized by Agricultural technology development Society (ATDS) Ghaziabad, Uttar Pradesh will provide a timely and relevant discussion forum for scientists, developmental agencies and policy makers and agricultural practitioners to share their innovations, experiences and expertise to better understand the challenges posed by emerging global issues and design strategies for sustainable development. I convey my best wishes to the organizers and wish them a grand success.

MESSAGE

I am happy to know that International Conference on “Advances in Agricultural, Biological and Applied Sciences for Sustainable Future” is being organized from October 20th-22nd, 2018 at Swami Vivekanand Subharti University, Meerut, Uttar Pradesh, India.

A focus on increasing food production without due concern for the environment is causing severe land and water degradation. What we need is to be able to produce wide variety of nutritious foods while having minimal impact on the environment - a sustainable food system. The sustainable development goals, signed by 193 world leaders in 2015, recognize that these challenges are interconnected and multidimensional. Technological innovations relating to agricultural science, biological science and applied science are vital to address the challenges to ensure production of enough food for increasing population in the sustainable manner.

The international conference is therefore very pertinent and timely. It is hoped that deliberations during the conference will generate road map.

I wish the conference a great success.

MESSAGE

I strongly feel that updating information and sensitizing the young thinkers to focus their minds towards current trends is the call of the day. The best way forward is organizing and participating in vibrant conference which is the key character of the Agricultural Technology Development Society (ATDS) Ghaziabad, Uttar Pradesh, India, Swami Vivekanand Subharti University (SVSU), Meerut, Uttar Pradesh, India and Faculty of Agriculture, Cairo University (CU), Egypt who is jointly organizing three days 2nd International conference on 'Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)' scheduled to be held on October 20-22, 2018 at Sardar Patel Auditorium, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh, India in collaboration with Bulletin of Environment, Pharmacology and Life Sciences (BPELS), Agra, Uttar Pradesh, India, National Gladiolus Trust (NGT), Jammu, Jammu & Kashmir, India and International Journal of Pure and Applied Bioscience (IJPAB), Kota, Rajasthan, India. The conference is aimed to provide a common platform to scientists, researchers, academicians, professionals, social workers, policy makers as well as farmers and expertise corporate to exchange their new ideas and recent research findings with colleagues from within and outside India, which will boost their knowledge and experience. In this global event scientists across the world are participating from the foreign countries like Malaysia, Philippines, Egypt, UK, Eritrea, Sudan, Nepal etc. The current conference will be perceived as a place where learner can develop according to their unique needs and potential and means of achieving greater social equality. Under present circumstances we are passing through a period of value crisis in fundamental research. Values determine human behavior in a significant way.

The current International Conference under the flagship of Dr. Joginder Singh is well articulated and timely efforts to achieve the sustainability.

I wish this conference a grand success with a hope to see a policy document after the conference.

Sincerely yours,

MESSAGE

Demands for food, feed, water and shelter is increasing in quantity and quality day by day to meet the requirement of burgeoning population of the globe. Present global population of 7.6 billion expected to breach/reach 10 billion mark by 2050. India is home about 17% of world human being. The country is witnessing population growth at much faster rate than other part of the world and from present level of 1.37 billion, it is expected to reach 1.53 and 1.68 billion in years 2030, 2050, respectively. Besides, growing population, which puts excessive pressure on our natural resources, climate change is a major threat to the sustainability of global biosphere in coming future. In this challenging environment, we need to be vibrant, dynamic and innovative in developing and adopting scientific knowledge and technology into our production system. In this background, the present International Conference on "Advance in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018) is very contemporary and expected to come out with fruitful, implementable recommendations.

Participation of large number of delegates with widely divergent background in this International Conference will provide and excellent common platform for the academicians, scientists, policy maker NGOs, students and farmers to interact and come up with practical recommendations for development of policies, researchable and developmental and biodiversity conservation.

I wish grand success of this International Conference to the organiser particularly to Agricultural Technology Development Society, Ghaziabad.

MESSAGE

Most Asian countries are Agriculture dependent; hence, development and prosperity of such countries rely on agricultural innovations and technologies. Attaining sustainable future or meeting global challenges of zero hunger to all people will be possible if and only if the profession of farming is honored or respected by the society and the nation. There is always scarcity of agricultural labors during peak season, youths today are more attracted to the world of IT and are always reluctant to opt farming profession. Unless significant investment and incentive to agrarian community backed by political will is guaranteed, farming will never be any choice of today's younger generation.

I am glad to know that Agricultural Technology Development Society, Ghaziabad , UP, India is organizing a three days “Second International Conference on Advances in Agricultural, Biological and Applied Science for Sustainable Future (ABAS-2018)” from 20 to 22 October, 2018 at Swami Vivekanand Subharti University, Meerut, UP, India to discuss issues related to various thematic areas for uplifting agrarian community through agricultural innovations and emerging technologies, which ultimately will boost morale of farming professions attracting young mind, heart and hands in agriculture for sustainable future. I am optimistic that this upcoming conference will be helpful in achieving its goal vis-a-vis in motivating agricultural professionals, investors, development workers, researchers and policy makers for bringing rapid agricultural transformation. The deliberation and resultant outcome of the conference will be of immense help to all those professionals related to agriculture.

I am really excited to be the part of the Conference and I convey my greetings and best wishes to organizers, sponsors, delegates, presenters and participants for the grand success of this mega event.

(Shree Prasad Vista)

Faculty of Agriculture, Cairo University, Egypt

MESSAGE

It is very pleased that the College of Agriculture, Cairo University, is among the sponsors and participants with 2nd International Conference Advances in Agriculture, Biological and Applied Sciences for Sustainable Future (ABAS-2018) on October 20th-22nd, 2018. I would like to extend my thanks and appreciation to everyone who suggested and agreed to this.

Monitoring, monitoring and analysing food security developments is one of the most important issues in the Developing countries because it is a food deficit zone in some major food commodities such as cereals, sugar and vegetable oils, and as one of the most geographically affected areas in the world. To address these and other variables, more serious efforts are required at the national national levels to achieve food security in its comprehensive sense. It is to provide material, social and economic opportunities for all people at all times to obtain adequate, safe and nutritious food that meets their nutritional needs and nutritional tastes and ensures that they live a better life, health and activity. It is therefore important that the Developing countries food security situation be monitored periodically by monitoring and analysing key areas related to food availability, access, stability and nutritional dimensions.

The international Conference enjoys the participation of outstanding experts in the field of plant production from all over the world. We believe that this Conference will be of multiple and invaluable significance as participate will have the opportunity the exchange experiences and to establish a possible collaboration between individuals and institutions.

The Faculty of Agriculture, University of Cairo, will represent two crop professors, Dr. El-Sayed Gheith and Dr. Ola El-Badry and we hope that our College will contribute to the next conferences with more efforts related to climate changes and desert cultivation.

We wish you very useful and fretful disruptions and recommended out of this conference. We would like to express our deep appreciation.

To all members of the Organising scientific committees for their effort and hard work the excreted to make this Conference successful.

I am glad to know that an International Conference on “**Advances in Agriculture, Biological and Applied Sciences for Sustainable Future**” (ABAS 2018) is being jointly organized by Agriculture Technology Development Society (ATDS) Ghaziabad, (U.P.) India in collaboration with Swami Vivekanand Subharti University, Meerut (U.P.) India and faculty of Agriculture, Cairo University, Egypt on October 20-22 at Sardar Patel Auditorium Swami Vivekanand Subharti University, Meerut (U.P.) India. I hope and believe that issue pertaining to various aspects of agriculture and biological innovations and their dissemination to the end users will be deliberated and discussed by the delegates during the conference for the benefit of mankind at global level. I am sure that this International Conference would succeed in getting its main objectives. The theme chosen for this conference is of utmost importance in today’s context as concerned for sustainable development. The themes of the conference are very relevant for the contemporary world. I am sure that this 2nd International Conference will deliberate on latest development in the field of Agriculture, Biological and Applied Science.

I am sure that the deliberations/discussions to be held in this conference on above themes will definitely pave way for the researchers, policymakers and stakeholders to address the future challenges for growth and development of agriculture sector and insure food security.

I express my sincere appreciation to all the organizers who are working day and night to make this conference success and also thanks and welcome all the delegates

I extend my best wishes for all round success of this conference.

I am delighted to learn that the Agriculture Technology Development Society (ATDS), Ghaziabad, Swami Vivekananda Subharti University (SVSU), Meerut and Faculty of Agriculture, Cairo University, Egypt are jointly organizing 2nd International Conference on “Advances in Agricultural, Biological and Applied Sciences for Sustainable Future” at Moot Court Conference Hall, SVSU, Meerut from October 20-22, 2018 to share the knowledge and expertise in the concerned areas based on the theme of the International Conference. Our Honorable Prime Minister Sri. Modi's dream is that in the year 2022 when our country will be celebrating its 75th Independence Day, the farmer's income of our country must become double to feed the ever growing population without any damage to the ecological foundation of agriculture such as land, water, forest, biodiversity and environment.

I am sure this International Conference will provide a unique platform for researchers, policy makers, stakeholders, NGO's, farmers and students to discuss and interact with each other on various issues for the growth and development of agriculture sector and ensure food and income security.

I would like to take this opportunity to congratulate the organizers and also extend my best wishes for the grand success of the conference.

MESSAGE

It is a matter of great privilege for me to organize 2nd International Conference on “Advances in Agriculture, Biological and Applied Sciences for Sustainable Future” (ABAS 2018) on October 20-22 at Sardar Patel Auditorium Swami Vivekanand Subharti University, Meerut (U.P.) India. On behalf of the organizing committee, I warmly welcome all the guests, participants, delegates, researchers and scientist in the conference. I am thankful to all honored guest and eminent scientist from in and outside India for sparing their valuable time to our International Conference. The main motive of the Conference is to bring together interdisciplinary ideas in the areas of Agricultural, Biological and Applied Sciences for Sustainable Development. This conference will create an opportunity for researches, academicians to gain new ideas and understand the recent advances in Agricultural, Biological and Applied Sciences. I am sure that this International Conference would succeed in getting its main objectives. The theme chosen for this conference is of utmost importance in today's context as concerned for sustainable development.

I am sure that scientific/ technical deliberation and discussion will be greatly benefited to the delegates, participants and policy makers. Moreover it will also help in solving different problem and issues.

I am also grateful to the members of various committees, my colleagues in the college and the department and supporting staff who worked day and night for the successful organization of the conference.

I am again delighted to welcome you all to this meeting and pray almighty to bless us for making this International Conference a grand success.

(Joginder Singh)

Secretary

Agricultural Technology Development Society (ATDS)

FROM THE DESK OF CHIEF ORGANIZING SECRETARY

This is a matter of great honor that Agricultural Technology Development Society (ATDS) Ghaziabad, Uttar Pradesh, India, Swami Vivekanand Subharti University (SVSU), Meerut, Uttar Pradesh, India and Faculty of Agriculture, Cairo University (CU), Egypt in collaboration with Bulletin of Environment, Pharmacology and Life Sciences (BPELS), Agra, Uttar Pradesh, India, National Gladiolus Trust (NGT), Jammu, Jammu & Kashmir, India and International Journal of Pure and Applied Bioscience (IJPAB), Kota, Rajasthan, India is jointly organizing an 2nd International Conference "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)' on October 20-22, 2018 at Sardar Patel Auditorium, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh. On this auspicious occasion, I warmly welcome all participants, delegates, Researchers and Scientist of different institutions, colleges and university from India and abroad. The organization of such a mega event will provide us an opportunity to assemble the learned delegates coming from different parts of the world like Egypt, Sudan, Nepal, Malaysia, Finland, USA and China.

The 2nd International Conference on 'Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)' has been design to focus on various scientific tracks covering major areas of research agriculture, biological and applied sciences. ABAS 2018 aim to accelerate scientific discoveries and major milestone in the current situation and innovation relating to agriculture, biological and applied sciences and also its relevant areas. The main motive of the conference is to bring together interdisciplinary idea and approaches in the area of agriculture, biological, chemical, physical and industrial process. I hope that this conference will create an opportunity for the researches, academicians to gain new ideas and understand the recent advances in agriculture, biological and applied sciences for sustainable development. I am sure that scientific/ technical deliberation and discussion will be greatly benefited to the delegates, participants and policy makers. Moreover it will also help in solving different problem and issues.

Organization of such mega event is impossible without team work. I like to express my sincere thanks to our Honourable Patrons and Directors of Swami Vivekanand Subharti University for providing us with the support and encouragement in organizing the conference. I express my sincere thanks to the members of the organizing committee, advisory committee, faculty members and staff for true labor, invaluable support and suggestions to make this conference a grand success.

I am again delighted to welcome you all to this meeting and pray almighty God to bless us for making this International Conference a grand success.

(Rashmi Nigam)

Date 12/10/2018

MESSAGE

I on behalf of organizing committee welcome you all to 2nd International Conference on “Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS -2018)” on October 20–22, 2018 at Sardar Patel Auditorium, Swami Vevakanand Subharti University, Meerut, Uttar Pradesh, India, organized by Agricultural Technology Development Society (ATDS), Ghaziabad, U.P., India. During the past fifty years, agricultural development policies have been remarkably successful at emphasizing external inputs as the means to increase food production. The global plant productivity is badly hit by unpredictable change in climate over the past few decades resulting in inadequate supply of plant products. Conversely, the worldwide population is predicted to surpass 9 billion by 2050 which will create scarcity of plant derived resources. The conservation of biodiversity to manage healthy agro-ecosystems via integrated approach of plant biology research might be one of the potential solutions to deal with food security in changing environment. The slow growth of farm income and new global trade regulations demand a paradigm shift has resulted in formulating the National Agricultural Research Programmes (NARP) to conserve natural resources in changing environment. Therefore, there is a need to introduce all these aspects of various strategies of crop improvement under environmental stress conditions with special emphasis to advanced biological-biotechnological perspectives in the field of agriculture. In the context of the foregoing, the first step in the right direction would come from educating and motivating young minds on the possibilities that this area entails for scientific exploration.

It will be an opportunity of sharing our expertise and experience with the renowned speakers from all over the world. It will also be a platform to strengthen the friendship and collaboration among the scientists, academia and the institutes.

The local organizing committee, under the valuable guidance of our Managing Chairman Dr. Joginder Singh, Executive Chairman's, Director's and Advisor's, has been very active and arrangements are well under way to ensure that the 2nd International Conference ABAS 2018 is a resounding success.

I appeal to the research community to extend their continued support and cooperation to the future activities of ATDS.

I look forward to welcoming you all in the Sardar Patel Auditorium, Swami Vevakanand Subharti University, Meerut, Uttar Pradesh, India.

(Dr. Wajid Hasan)

Organizing Secretary

2nd International Conference
Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS - 2018)
(20 – 22 October, 2018)

CONFERENCE PROGRAM SCHEDULE

Day-1 (Saturday) Date: 20.10.2018

8:00 am to 9:30 am: Registration

09:30-10:00 am: Breakfast

INAUGURAL SESSION

Time	Events	Felicitor
10.00-10.05	Lightening of Lamp	Dignitaries
10.05-10.10	Saraswati Vandana/Welcoming Song	Students
10.10-10.20	Felicitation of the guests	Organizing committee
10.20-10.35	Welcome Address & About the Conference	Dr. Rashmi Nigam, Chief Organizing Secretary
10.35-10.40	Release of Souvenir	Dignitaries
10.40-10.50	Welcome address of Dignitaries & About ATDS Society	Dr. Joginder Singh, Secretary, ATDS, Ghaziabad
10.50-11.00	Welcome address	Representative, Swami Vevakanand Subharti University, Meerut
11.00-11.10	Special Guest address	Dr. Shree Prasad Vista, Director, MARI, Jumla, Nepal
11.10-11.40	Special Guest address & Keynote Lecture	Prof. Mushahid Husain, Former-Vice Chancellor, M.J.P. Rohilkhand University, Bareilly, U.P
11.40-12.10	Special Guest address & Keynote Lecture	Dr. A. S. Panwar, Director, ICAR- IIFSR, Meerut, UP
12.10-12.20	Special Guest address	Representative, Cairo University, Egypt
12.20-12.50	Chief Guest Address	Prof. Gaya Prasad, Hon'ble VC, SVPUAT, Meerut, UP
12.50-1.00	Vote of thanks	Dr. Anant Kumar, President ATDS

01:00 - 02:00 pm: Lunch Break

TECHNICAL SESSION – I

2.00- 5.00 PM: Technical Session -1: Oral Presentation & Poster Session

THEME 1: Recent trends in Agricultural Sciences and Technology

Session Events: Invited Lectures, Oral Presentation

5.00- 5.15 PM: Evening Tea

TECHNICAL SESSION – II

Day-2 (SUNDAY) Date: 21.10.2018

08:30-9:00 am: High Tea

9.00- 11.15 AM: Technical Session -2: Oral Presentation & Poster Session

THEME 2: Environmental and livelihood security for sustainable Development

Session Events: Invited Lectures, Oral Presentation

11.15- 11.30 am: Breakfast

TECHNICAL SESSION – III

11.30- 2.00 PM: Technical Session -3: Oral Presentation & Poster Session

THEME 3: Advances in Biological Sciences and Biodiversity Conservation

Session Events: Invited Lectures, Oral Presentation

02:00 - 3:00 pm: Lunch Break

TECHNICAL SESSION – IV

03.00- 5.30 PM: Technical Session -5: Oral Presentation & Poster Session

THEME 4: Innovative Approaches in Applied Sciences and Socio-economic Development

Session Events: Invited Lectures, Oral Presentation

5.30- 5.45 PM: Evening Tea

TECHNICAL SESSION – V

Day-3 (Monday) Date: 22.10.2018

08:30-9:00 am: Breakfast

9.00- 12.00 AM: Technical Session -5: Oral Presentation & Poster Session

THEME 1: Recent trends in Agricultural Sciences and Technology

Session Events: Invited Lectures, Oral Presentation

VALEDICTORY SESSION

Time	Events	Facilitator
12.00-12.10	Felicitation of the Dignitaries	Organizing committee
12.10-12.20	Welcome Address of the Dignitaries	Dr.Rashmi Nigam, Chief Organizing Secretary
12.20-12.30	Welcome Address of the Dignitaries	Dr.Anant Kumar, President ATDS
12.30-12.40	Welcome address	Representative, Swami VevakanandSubharti University, Meerut
12.40-12.50	Felicitation of ATDS-2018 Awardees	Dignitaries
12.50-1.00	Conference Reports	Dr.Neelesh Kapoor, Organizing Convener
1.00-1.10	Special Guest address	Prof.SaketKushwaha, VC, Rajiv Gandhi University, Itanagar, Arunachal Pradesh
1.10-1.20	Special Guest address	Dr. Manoj Kumar, Joint Director, ICAR-CPRI, Meerut, UP
1.20-1.30	Special Guest address	Representative, Cairo University, Egypt
1.30-1.40	Special Guest address	Mr.Bishnu Prasad Bhattarai, Head, Agricultural Programme, HICAST, Kathmandu, Nepal
1.40-1.50	Chief Guest Address	Dr. S. K. Malhotra, Agriculture Commissioner, KrishiBhawan New Delhi
1.50-1.55	Special Announcement	Dr.WajidHasan, Organizing Secretary
1.55-2.00	Vote of Thanks	Prof. Ram JiLal, Retd. Prin. Scientist, ICAR-IISR, Lucknow, UP

2:00 pm - 3:00 pm: Lunch Break

Important Instructions:

- 1). Duration for Keynote Address (15 mins); Invited Lectures (10 mins); Oral Presentations (05 mins).
- 2). Poster Sessions will be organizing on 20, 21 & 22 October, 2018 with the following schedule:
Day-1, 20 October: 02:00-05:00 PM- Theme 1: Recent trends in Agricultural Sciences and Technology
Day-2, 21 October: 9.00- 11.15 AM - Theme 2: Environmental and Livelihood Security for Sustainable Development
11.30- 2.00 PM Theme 3: Advances in Biological Sciences and Biodiversity Conservation
03.00- 5.30 PM -Theme 4: Innovative Approaches in Applied Sciences and Socio-economic Development
Day 3, 22 October: 9.00- 12.00 AM:Theme 1: Recent trends in Agricultural Sciences and Technology
(Venue: Auditorium Lobby).
- 3). Dimensions for Posters (clearly visible flex print/digital print/other good quality print): 25 x 38 inches or 34 x 46 inches.
- 4). All participants are requested to upload their Power Point presentations/deposit their posters at Registration Counters.
- 5). For any amendments/rectifications related to Oral/Poster presentations, please contact at Registration counters.
- 6). Registration counters will be closed during Inaugural Function (10:00-12:00 PM).
- 7). ATDS-2018 Awardees must report one hour before the prescribed time.

Conference Organizing Committee

Chief – Patron

- Prof. N.K. Taneja, Hon'ble VC, CCS University, Meerut, UP
- Prof. Gaya Prasad, Hon'ble VC, SVPUAT, Meerut, UP
- Prof. S. Solomon, Hon'ble VC, CSAUAT, Kanpur, UP
- Prof. A. K. Singh, Hon'ble VC, BAU, Sabour, Bihar
- Dr. S. K. Malhotra, Agril. Commissioner, Krishi Bhawan, New Delhi

Executive Patron

- Prof. N. K. Ahuja, Hon'ble VC, SVSU, Meerut, UP
- Prof. Saket Kushwaha, Former VC, LNMU, Darbhanga, Bihar
- Prof. Ram Chandra, Hon'ble VC, Monad University, Hapur, UP

Chairperson

- Dr. A. S. Panwar, Director, ICAR- IIFSR, Meerut, UP
- Dr. P. L. Saroj, Director, ICAR-CIAH, Bikaner, Rajasthan
- Dr. Manoj Kumar, Joint Director, ICAR-CPRI, Meerut, UP

Executive Chairperson

- Prof. Samsher, Dean (Ag.) SVPUAT, Meerut, UP
- Prof. Ravindra Kumar, Dean (Biotech) SVPUAT, Meerut, UP
- Dr. Shree Prasad Vista, Director, MARI, Jumla, Nepal
- Dr. R. K. Sohane, DEE, BAU, Sabour, Bihar
- Dr. Pratap Singh, Dean, Monad University, Hapur, UP

Conference Director

- Prof. Jitendra Kumar, Dean (Ag.) CCSU, Meerut, UP
- Prof. Chandra Sen, BHU, Varanasi, UP
- Dr. Manoj Nazir, Directorate of Ag, Jammu, J & K

Executive Director

- Prof. Ram Ji Lal, Retd. ICAR-IISR, Lucknow, UP
- Dr. Rajendra Uperti, RAD, Biratnagar, Nepal
- Prof. Bijendra Singh, SVPUAT, Meerut, UP
- Dr. Duraimurugan P., ICAR- IIOR, Rajendranagar, Hyderabad

Associate Director

- Prof. & Head Satya Prakash, KVK (Ghaziabad), SVPUAT, UP
- Dr. Arvind Kumar, Regional Director, ARI, Patna
- Dr. Name Singh, ICAR-CPRI, Meerut, UP
- Dr. O. P. Sharma, NIPHM, Rajendranagar, Hyderabad
- Prof. Gopal Singh, SVPUAT, Meerut, UP

Executive Chairman

- Dr. Krishan Pal Singh, ICAR-IARI, New Delhi
- Dr. Mukesh Kumar, SVPUAT, Meerut, UP
- Dr. Surendra Ram, KVK, Faizabad (NDUAT) UP
- Dr. Suresh Chandra, SVPUAT, Meerut, UP

Organizing Vice-Chairman

- Dr. Hariom Katiyar, SVPUAT, Meerut, UP
- Mr. Ashwani Kumar, CSSSC, Machhra, Meerut, UP
- Mr. Heera Lal, JVC (CCSU) Baraut, Baghpat, UP

Conference Steering Committee

- Dr. Mohamed Elfadi, University of Helsinki, Finland
- Dr. Ed Rajotte, Pennsylvania State University, USA
- Prof. Atef M.A. Amin Elansari, Alexandria University, Egypt
- Dr. Kon Daniel Awan Arik, Republic of South Sudan, Juba
- Prof. Shabbir Ashraf, AMU, Aligarh, UP, India
- Prof. Mohsen El. Batran, Vice-Dean, Cairo University, Egypt
- Dr. Sunil Kumar, NEHU, Tura Campus, Meghalaya, India
- Dr. Riaz Ahmad Afridi, SRO, ARI, Tarnab Peshawar, Pakistan
- Dr. Dutta Dhale, DPRGSC, Dhule, MH, India
- Prof. El-Sayed M. Gheith, Faculty of Agriculture, Cairo Univ., Egypt
- Dr. Suzylawati Ismail, University Sains Malaysia, Penang, Malaysia
- Prof. Tapan Kumar Maity, Ex. Dean, BCKV, West Bengal, India
- Mr. Fathi Ibrahim A. Brima, University of Bahri, Sudan
- Mr. Pankaj Prakash Joshi, FHENP, Chitwan, Nepal
- Prof. Surajit Mitra, BCKV, West Bengal, India
- Prof. D. K. Singh, GBPUAT, Pantnagar, UK
- Dr. Mushtaque Ahmed, Sultana Quboos University, Oman
- Prof. Ola Z. El-Badry, Faculty of Agriculture, Cairo Univ., Egypt

- Dr. Mahak Singh, Deptt. of Agronomy, CSAUST, Kanpur UP
- Dr. Kushagra Rajendra, Amity University, Haryana, India
- Dr. Solomon Abate, Madawaalbu University, Bale Robe, Ethiopia
- Prof. R.S. Sengar, SVPUAT, Meerut, UP, India
- Dr. Faiza Md. Abdelmagid, Univ. of Bahri, Khartoum, North Sudan
- Mrs. Shazia Naqsh Bandi, Istanbul, Turkey
- Dr. R.U. Khan, Aligarh Muslim University, Aligarh, UP, India
- Mr. Muhammad Ali, UMT, Lahore, Pakistan
- Dr. Aijazul Islam, SKUAST, Srinagar, J & K
- Dr. Mohammad Wasi Ahmed, COE, Salah, Oman
- Dr. Mohammed Wasim Siddiqui, BAU, Sabour, Bihar, India
- Dr. Saima Hashim, University of Agriculture, Peshawar, Pakistan
- Prof. Abdul Malik, Aligarh Muslim Univ., Aligarh, UP, India
- Prof. D. N. Harit, GCC, Champai, Mizoram, India
- Dr. A. Manickavelu, SBS, CUK, Kasaragod, Kerala India
- Dr. L. R. Meena, ICAR-IIFSR, Meerut, UP, India
- Ms. Asifa Hameed, Pennsylvania State University, USA
- Dr. S. R. Shirodkar, GCC, Ankola (UK), KN, India
- Dr. V. K. Dwivedi, JVC (CCSU) Baraut, Baghpat, UP, India

Co-Organizing Secretary

- Dr. Harikesh Singh, GMV, Saharanpur, UP
- Dr. Amit Kumar, SKUAST, Srinagar, J & K
- Dr. Poonam Kashyap, ICAR-IIFSR, Meerut, UP
- Dr. Rajendra Singh, PAU, Ludhiana, Punjab
- Dr. S. L Pal, RSMC, Dhampur, Bijnor, UP

HORTICULTURE BASED INTEGRATED FARMING SYSTEMS FOR DOUBLING FARMERS' INCOME**A.S. PANWAR, POONAM KASHYAP, N. RAVISANKAR, A. K. PRUSTY, SUNIL KUMAR, AMRIT LAL MEENA AND JAIRAM CHOUDHARY***ICAR-Indian Institute of Farming Systems Research, Modipuram, Meerut, U P, 250110*

With the ever increasing population coupled with degrading land resources, a larger part of the population is already having difficulty in securing quality food. It is necessary to think of innovative and creative ways to feed and nourish everyone. A paradigm shift in farming systems research is the utmost need to accomplish the mission by integrating the modern tools and techniques of agriculture. Horticulture crops such as vegetables, fruits, plantation, spices, floriculture, medicinal and aromatic plants have greater role in farming systems in meeting the objectives of better soil, family nutrition, round the year production and income besides environmental improvement. Through Horticulture based farming systems, the resources are effectively utilized, resources are conserved well and environment is improved. In all the Integrated farming system models being developed through AICRP-IFS, two components viz., boundary plantation and kitchen garden are integrated with an aim to supply the fresh quality fruits and vegetables for the family especially to children who are the future human resource of this country. Among the 38 On-station farming system models developed through AICRP on Integrated Farming Systems network, eight horticulture-based farming system models have been developed for the country. Farming system has the in-built mechanism of sustainability due to presence of many inter-linked complementary and supplementary enterprises. In the event of aberrant weather and market price, integrated farming system ensures the farmers, thereby increases the sustainability. Further, wastes from one components are recycled as input for other components and thereby it also contributes positively to the soil health, crop growth and environment. Our results clearly indicate that IFS models are more sustainable than the practices of cropping system or dairy alone. (Gangwar *et al.*, 2015) The prevailing farming situation in India calls for an integrated effort to address the emerging issues / problems. The integrated farming systems approach is considered to be the most powerful tool for enhancing profitability of farming systems, especially for small and marginal farm-holders to make them bountiful. In fact, our past experience has clearly evinced that the income from cropping alone is hardly sufficient to sustain the farmers' needs. With enhanced consumerism in rural areas, farmers' requirements for cash have also increased to improve their standard of living. This is especially true in case of small and marginal farmers. Therefore, farmers' income and food requirements would have to be augmented and supplemented by adoption of efficient secondary/ tertiary enterprises like horticulture (vegetables/ fruits/ flowers/ medicinal and aromatic plants), apiary, mushroom cultivation, fisheries etc. However, these integrated farming systems will be required to be tailor-made and designed in such a manner that they lead to substantial improvement in energy efficiencies at the farm and help in maximum exploitation of synergies through adoption of close cycles. These systems also need to be socially acceptable, environment friendly and economically viable (DARE, 2015)

The ever increasing population of our country is causing a threat to Indian agriculture by creating diverse challenges and problems. The demand for food, feed, fodder and natural resources is creating a constant pressure to develop efficient agricultural systems which can suffice a farmer's need. Marginal and small farmers, representing more than 86% of Indian farm families with land holding below 1.2 ha, live in risk-prone diverse production conditions. Due to ever increasing population and decline in per capita availability of land, there is less or no scope for horizontal expansion of land for agriculture. Crop and livestock cannot be separated for small holder agriculture in India as crop + livestock is the pre-dominant farming system existing in the country and livelihood of 117 million marginal and small farm holdings revolves around this system. Small categories of farms are often subjected to weather vagaries like flood, drought and other natural calamities and farming remains risky. Vertical expansion in small farms is possible by integrating appropriate farming system components requiring less space and time and ensuring periodic income to the farmers. Integrated Farming System (IFS) is considered to be powerful tool and holds the key for ensuring income, employment, livelihood and nutritional security in a sustainable mode for small and marginal farmers who constitute 84.97 % of total operational holdings and operated 44.31 % of area. Integrated system meets the above goals through multiple uses of natural resources such as land, water, nutrients and energy in a complimentary way thus giving scope for round the year sustainable income from various enterprises.

Integrated farming system approach is not only a reliable way of obtaining fairly high productivity with considerable scope for resource recycling, but also covers concept of ecological soundness leading to sustainable agriculture. In the farming system approach, horticulture provides excellent opportunities in raising the income of the farmers even under abrasive conditions. The cultivation of fruit crops under horticulture based farming system (HBFS) plays an important role in the prosperity of a nation along with health, happiness, prosperity of the people and ensures sustainable farm income under abrasive climatic conditions. Integration of horticultural modules in farming systems aid in enhancing the productivity and profitability of the farming systems specially with cultivation of vegetables (Kashyap *et al.* 2015). The natural resources can be explored to its maximum potential in a complimentary way so as to harvest maximum returns from various enterprises of the systems through integrated farming systems.

INTEGRATED FARMING SYSTEM APPROACH AND ITS OBJECTIVES

IFS approach can be described as “A judicious mix of two or more components using cardinal principles of minimum competition and maximum complementarity with advanced agronomic management tools aiming for sustainable and environment friendly improvement of farm income, family nutrition and ecosystem services”. Preservation of bio-diversity, diversification of cropping/farming system and maximum recycling is the base for success of the farming systems approach (Singh and Ravisankar, 2015).

FARMING SYSTEMS AND ITS COMPOSITION IN INDIA

Characterization of existing farming systems throughout the country indicates existence of 19 pre-dominant farming systems with majority as crop + livestock (85%). Although crop + livestock system is dominating in the country, based on the percent contribution to net income, the systems are classified as crop, horticulture, livestock, fisheries dominant systems where in dominant component contributes more than 50 % of the total net returns. Accordingly, it has been found that horticulture based farming systems exists in the states of Goa, Kerala, Meghalaya, Rajasthan, Uttar Pradesh, Andaman and Nicobar islands, crop dominant farming systems are existing in the states of Andhra Pradesh, Bihar, Chhattisgarh, Goa, Haryana, Jammu and Kashmir, Jharkhand, Kerala, Karnataka, Madhya Pradesh, North-East, Maharashtra, Odisha, Punjab, Tamil Nadu, Uttar Pradesh and Uttaranchal while livestock dominant systems are observed in Rajasthan and Gujarat. West Bengal, parts of Odisha and Assam states have the fisheries as a major source of income to the existing farming systems. The scope for promotion of horticulture (fruit) based systems exists in Jammu and Kashmir, Himachal Pradesh, Maharashtra, parts of Uttar Pradesh and in Sikkim while plantation crops dominant systems are found in Andaman and Nicobar Islands and Kerala.

In selected states and locations, highly diversified systems also exists where in none of the component contributes for 50 % or more to the returns. Though the various farming systems are existing naturally in the country, integration of output as input to other components within the system is either completely lacking or at partial.(Manjunatha *et al.*, 2014) Competition exists within and outside the farm for various byproducts generated. Sustainable farming systems should aim for long term productivity, profitability, recycling of resources and employment generation.

MAJOR HORTICULTURE BASED FARMING SYSTEM MODELS DEVELOPED IN DIFFERENT STATES OF INDIA

Region specific horticulture based farming systems with special emphasis on most suitable horticultural crop of the region viz., plantation crops, fruit crops, exotic vegetables etc. can address essential requirements of productivity, profitability and sustainability besides employment generation. Here are 8 different horticulture based farming systems developed for different states as listed as under.

i) Orchard-based IFS model for Uttar Pradesh (1.5 ha)

Orchard based IFS model has been developed for Uttar Pradesh. The major components of the models are 1) Horticulture + intercrop systems (0.8 ha.), 2) Crops (0.6ha) and 3) Pond Dyke system (0.10 ha.). The production achieved through the model is 41t/yr (rice eq. yield) with annual net income of 4.29 lakhs/yr, generating employment of 742 mandays/yr.

ii) Coconut-based Farming System for Andaman & Nicobar island (1 ha)

A coconut based farming system model (1.0 ha) has been established for Andaman and Nicobar island. The major components of the models are 1) Coconut based multi-tier systems 0.8 ha. 2) Livestock – 4 pigs 3) Fish cum poultry 0.06 ha. 4) V.C. – 0.01 ha. The total production achieved from the model is 36t/year (REY) with a total cost of 1.70 lakhs/year. The annual income obtained through this model is Rs. 2.23 lakhs/year, besides generating employment of 198 mandays/year.

iii) Coconut-based multi-tier cropping model for Kerala (0.2 ha)

Coconut based multi-tier cropping model has been developed for Kerala. The major components of the models are 1) Coconut based multi-tier cropping systems (0.19 ha.) 2) livestock – .01ha. 2 cows, 3) Fish culture between coconut bunds and Azolla. The production of the model is 11t/year (REY) with annual net income of Rs. 0.57 lakh/year, generating employment of 127 mandays/year.

iv) Homestead based IFS model for Kerala (0.2 ha)

Homestead based cropping model has been developed for Kerala. The major components of the models are 1) Homestead based cropping systems (0.16 ha.) 2) Livestock – 0.01ha, 2 cows 3) Terrace garden + water harvesting, 0.15 ha.) 4) Vermi compost (0.006ha.) and poultry unit (0.01ha). The production of the model is 1,9,800 numbers/year (coconut eq. yield) with an annual net income of Rs. 0.35 lakh /year generating employment of 82 mandays/year.

v) Banana-based IFS model for Kerala (0.2 ha)

Banana based IFS model has been developed for Kerala. The major components of the models are ; 1) Horticulture + intercrop systems (0.18 ha.) 2) livestock's – .01ha. 2 cows 3) Vermi compost (0.01ha). The production of the model is 4t/year (banana eq. yield) with annual net income of Rs. 4.29 lakh/year generating employment of 742 mandays/year.

vi) Exotic vegetables-based IFS model for Uttar Pradesh (0.4 ha)

Exotic Vegetables based IFS model has been developed for Uttar Pradesh. The major components of the models are ; 1) Exotic Vegetables (0.34 ha.) 2) Livestock (0.06ha.) with 1 buffalo +1 cow. The production of the model is 19.6t/year

(REY) with annual net income of Rs. 2.03 lakh/year generating employment of 367 mandays/year share obtained from coconut based multi-tier systems.

vii) Plantation crop based IFS model for Goa (0.80ha)

Plantation based IFS model has been developed for Goa. The major components of the models are ; 1) Plantation crop based (0.70 ha.) 2) Livestock–. 8 pigs & 25 birds 3) Vermi compost (0.10ha.). The production of the model is 23t/year (REY) with annual net income of Rs. 0.89 lakh/year generating employment of 508 mandays/year.

viii) Fruit tree based IFS model for Rajasthan (1.0ha)

Fruit tress based IFS model has been developed for Rajasthan. The major components of the models are; 1) Fruit tress + crop based (0.87 ha.) 2) Livestock –1cow 3) Others Vermi compost (0.13ha.). The production of the model is 7.8t/year (cluster bean eq. yield) with annual net income of Rs 0.97 lakh /year generating employment of 225 mandays/year.

Comparative performance of these 8 horticulture based farming systems models (HBFS) in terms of production and economics has been presented in Table 2 which suggests important role of horticulture based farming systems in enhancing productivity, profitability and employment generation.

Table 1: Performance of horticulture based farming systems models in terms of production and economics

Location	IFS Model	Area	Production (Equivalent yield of base crop of region) (t/year)	Annual Net profit (lakh/year)	Empower (Man- days/year)
Andaman & Nicobar island	CBFS + Pig based IFS model	1.0	36 (rice eq. yield)	2.23	198
Goa	Plantation + Pig + Poultry	0.8	23 (rice eq. yield)	0.89	508
Kerala	Coconut based IFS model	0.2	11 (rice eq. yield)	0.57	127
Kerala	Homestead based IFS model	0.2	19800 nos /year (Coconut eq. yield)	0.35	82
Kerala	Banana based IFS model	1.58	4 (Banana eq. Yield)	0.16	96
Rajasthan	Agroforestry based IFS model	2.0	5.9 (pearl millet eq. yield)	0.50	192
Rajasthan	Agri-horti based IFS model	2.0	15.1 (pearl millet eq. yield)	1.32	350
Rajasthan	Horti-pasture based IFS Model	2.0	6.5 (pearl millet eq. yield)	0.52	210
Rajasthan	Agri-silviculture based IFS model	2.0	5.0 (pearl millet eq. yield)	0.49	192
Rajasthan	Fruit tress + field crop + medicinal plant based IFS	1.0	7.8 t (cluster bean eq yield)	0.97	225
U.P.	Orchard based IFS model	1.5	41 t (rice eq. yield)	4.29	742
U.P.	Exotic vegetable based IFS model	0.4	19.6 (rice eq. yield)	2.03	367

CONCLUSION

It can be concluded that diversification of existing farming systems with change in crops, cropping systems, addition and improvement of livestock components, inclusion of horticulture, kitchen garden, primary and secondary processing, boundary plantations are essential to improve the on-farm income of small holders in India. This also paves way for meeting the household demand of balanced food, improved recycling of nutrients and water besides increasing the on-farm employment for family. Diversification of existing farming systems clearly demonstrated the advantages. It has been observed that productivity gain of 2 to 3 times and increase in net return of 3 to 5 times is possible with improved systems. Further, resource saving of 40 to 50 % can also be ensured besides enhancing the income of household to the level of atleast Rs 400 to 500/day. Additional employment generation of 70 to 80 % is also possible. Improved diversified horticulture based farming systems also ensure household nutritional security apart from providing the livelihood and smile security.

EVALUATION OF SOME WHEAT GENOTYPES UNDER SOWING DATES AND NITROGEN LEVELS: 1. GROWTH AND STRAW YIELD**EL-SAYED M. GHEITH, AHAMAD ABDEL SHAHEED, OLA Z. EL-BADRYANDSAFAA A WAHID***Agronomy Department, Faculty of Agriculture, Cairo University, Egypt*

A study on the response of five wheat genotypes (Sids 1 and Gemmiza 9 from Egypt, L.R.-52 from Sudan, L.R.-62 and L.R.-67 from Yemen) to three sowing dates (25th November, 10th and 25th December) and two nitrogen levels (120 and 240 kg N/ha.) was conducted at the Agricultural Experimental and Research Station, Faculty of Agriculture, Cairo University, Egypt during 2011/2012 and 2012/2013. The experiment was laid out in RCBD in a split plot design, placing sowing dates in the main plots, nitrogen levels in the sub plots and genotypes in the sub sub-plots with three replications. Sowing dates had significant effect on the number of days to 50% heading, flag leaf area, plant height and straw yield in both seasons. The highest values of the previous traits were obtained at early sowing on 25th November in both seasons. All the studied traits significantly increased by increasing nitrogen levels up to 240 kg N/ha. The genotype L.R.-67 emerged 50% of its heads earlier, Gemmiza 9 and L.R.-67 gave taller plants, L.R.-62 produced the highest number of tillers, whereas Gemmiza 9 and L.R.-62 produced the highest straw yield in both seasons. The earliest heading and the largest flag leaf area were obtained from sowing on 25th December at 240 kg N/ha. in both seasons. Late sowing (December) and low nitrogen applications significantly declined the yielding capacity of the wheat genotypes. Gemmiza 9 and L.R.-62 performed better in term of straw yield as compared to the other genotypes.

Key words: *Wheat, sowing dates, N levels, genotypes.*

INTRODUCTION

Wheat (*Triticum aestivum* L.) is considered the most strategic crop for Egypt and some other developing countries. Increasing wheat production is a national target in Egypt to fill the gap between consumption and production. Great attention and efforts have been paid by the Egyptian government and scientists to narrow wheat security gap. Man is dependent on wheat crop for food and for feed for his domestic animals because wheat straw is very important for livestock feed. Planting date is one of the most critical considerations and agronomic factors involved in producing high yield of small grain cereal crops like wheat. Several studies documented the effect of planting dates on wheat performance. Early or late sowing increases the risk of yield losses (Ali et al., 2010; Madani et al., 2010; Mostafa et al., 2010; HasinaGul et al., 2012). Similarly, plant height (Abdel-Hadi and El-Naggar, 2010; HasinaGul et al., 2012;), number of tillers/m² (RakeshKumar Sharma, 2003), straw and biological yields (Ali et al., 2010; Alisial et al., 2010; Mostafa et al., 2010) were increased with early sowing (early November) over late sowing (December). Nitrogen fertilization is the most important factor in front of wheat agronomist for achieving yield targets. Several investigators found positive response of wheat to nitrogen fertilization (El- Gizawy, 2009; Madani et al., 2010; Abedi et al., 2011; Ooro et al., 2011; Qi Wang et al., 2012), as well as to genotypes (Giambalov et al., 2010; Iqbal et al., 2012). The present project was therefore designed to investigate the effect of sowing dates and nitrogen levels on growth and straw yield of some wheat genotypes

MATERIALS AND METHODS

Study on the response of five wheat genotypes, (Sids 1 and Gemmiza 9 from Egypt, L.R.-52 from Sudan and L.R.-62 and L.R.-67 from Yemen) to three sowing dates (25th November, 10th December and 25th December) and two nitrogen fertilizer levels (120 and 240 kg N/ha.) was conducted at the Agricultural Experimental and Research Station, Faculty of Agriculture, Cairo University, Egypt during 2011/2012 and 2012/2013. The experiment was laid out in Randomized Complete Block Design (RCBD) in a split plot design placing sowing dates in the main plots, nitrogen fertilizer levels in the sub plots and genotypes in the sub sub plots with three replications. The net of sub sub plot area was 8 m² (twenty rows, two meters long and 20 cm apart). Seed bed was prepared by ploughing the field for 3 times with cultivator followed by planking. Wheat grains (144 kg/ha.) were sown manually with single row hand drilling by maintaining row to row distance of 20 cm. The soil was clay loam in texture, chemical and mechanical analyses are presented in Table (1). The amount of nitrogen in the form of urea (46%N) was added as per treatment in two portions, being applied immediately at sowing and the rest was applied at the time of first irrigation. All plots received uniform cultural practices. Data about the number of days to 50% heading, flag leaf area at 100 days from planting, plant height, number of tillers/m² and straw yield/ha. were recorded as recommended procure. The recorded data were analyzed statistically by using statistical software package MSTAT-C (Michigan State University, 1990). Least Significant Differences (L.S.D.) at 0.05 probability was employed to test the significant differences among mean values of each treatment (Steel and Torrie, 1997).

Table 1: Mechanical and chemical analysis of upper 30 cm of soil in both seasons.

Mechanical analysis	1 st season	2 nd season	Chemical analysis	1 st season	2 nd season
Clay %	38.2	37.2	Available N (ppm) ¹	46.5	49.8
Silt %	23.4	24.6	Available P (ppm) ²	13.7	15.3

Organic matter	1.6	1.9	pH	7.7	7.6

Calcium carbonate %	3.0	3.2	Ecmmhos/c 25C ⁰	2.4	2.4
Texture	C. loam	C. loam			

1, 2 and 3 = N, P and K according to Jackson (1958), Olsien et al. (1945) and Pipper (1960), respectively..

RESULTS AND DISCUSSION

Effect of sowing dates

Results presented in Table (2) show that number of days to 50% heading, flag leaf area, plant height and straw yield were statistically affected by sowing dates in both seasons. Tallest plants (115.17 and 112.43 cm) were observed at early planting (25 November), while smallest plants (96.57 and 94.37 cm) were recorded at later planting (25 December) in both seasons. Plants sown on November 25 came very late to heading (106.07 and 98.63 days) compared with the late planting in 25 December (89.63 and 83.03 days) in both seasons, respectively. Likewise, Number of tiller/m² and flag leaf area were decreased with delaying sowing date from 25 November to 25 December in both seasons, respectively. Therefore, early sowing in 25 November increased straw yield by 102.6% and 129.9% in the first season and by 88.0% and 102.3% in the second one compared with sowing in 10 and 25 December, respectively. Similar results were given by RakeshKumar Sharma (2003), Hamam and Khaled(2009) Abdel-Hadi and El-Naggar (2010) and Mostafa et al. (2010) who found that delay in sowing from 15 November to 15 December decreased these traits.

Table 2: Effect of sowing dates on studied traits in both seasons.

Sowing dates	Plant height (cm)		No. of days to 50% heading		No. of tillers/m ²		Flag leaf area(cm ²)		Straw yield (t/ha.)

Effect of nitrogen levels

All studied characters except number of tillers/m² were significantly affected by nitrogen levels in both seasons Table (3). Tallest plants (108.66 and 106.02 cm) were observed at 240 kg N/ha., while smallest plants (103.98 and 108.82 cm) were recorded at 120 kg N/ha. in both seasons, respectively. These results may be due to the stimulation effect on internodes elongation. Iqbal et al. (2012) and HasinaGul et al. (2012) reported similar results.

It is evident from these results that heading was delayed from 96.75 to 97.75 days in the first season and 89.64 to 91.09 days in the second one by increasing nitrogen application from 120 to 240 kg N/ha. This increment in heading period may be due to nitrogen addition that favored vegetative growth which in turn delayed time of heading. These results are in harmony with those obtained by Hamamand Khaled (2009). The highest flag leaf area (55.11 and 53.63) was obtained at 240 kg N/ha., while the lowest values (50.05 and 48.58) were produced at 120 kg N/ha. in both seasons, respectively. Nitrogen fertilization also has prominent effect on straw yield in both seasons. The application of 240 kg N/ha. increased straw yield by 17.0% and 10.9% over the lowest nitrogen level (120 kg/ha.) in both seasons, respectively. This might be due to the well utilization of nitrogen fertilizer in metabolism and meristic activity which improved growth characters such as plant height and number of tillers/m². These results are in agreement with those obtained by AnureetKaurPannu and Buttar (2010) and Qi Wang et al. (2012) who found that the largest straw yield per unit area was obtained by application of 240 – 360 kg N/ha.

Table 3: Effect of nitrogen levels on studied traits in both seasons.

Effect of genotype

Genotypes had significant effect on plant height, number of days to 50% heading, flag leaf area, number of tiller/m² and straw yield in both seasons (Table 4). As regarding to plant height, Gemmiza 9 was the tallest one (109.00 and 106.06 cm) followed by L.R.-62 (106.06 and 103.50 cm), while the shortest plants were recorded either by Sids 1 (105.17 and 103.17 cm) or L.R.-67 (105.17 and 103.17 cm) in both seasons, respectively. AS regarding to 50% heading, results indicated that L.R.-62 ranked first (95.17 and 88.33 days) followed by L.R.-62 (96.00 and 88.89 days) and Sids 1 (96.61 and 90.00 days), while Gemmiza 9 (98.33 and 91.89 days) ranked fourth and L.R.-67 (100.33 and 92.50 days) came 5th in both seasons, respectively. Concerning number of tillers/m², the highest number of tillers/m² (612.78) was observed from L.R.-62, while the lowest value (478.89). was recorded by Gemmiza 9 in the first season. Whereas, L.R.-67 (520.38) ranked 1th and Sids 1 (402.22) ranked 5th in the second season. These results are in agreement with those obtained by Menshawy (2007) and Njuguna et al. (2010) who found that genotypes showed a different effect on this trait. Mean straw yield comparison indicated that the highest yield (3.91 and 2.03 t/ha.) was belonged of Gemmiza 9, while the lowest yield (3.09 and 1.62 t/ha.) was recorded by Sids 1 in both seasons, respectively. These results are in harmony with obtained by Menshawy (2007), Njuguna et al. (2010) and Iqbal et al.(2012).

Table 4: Effect of genotypes on studied traits in both seasons.

Effect of interactions

Planting early in 25 November and application of 120 kg N/ha. increased number of days to 50% heading by 15.80 and 26.07 days compared with planting on 25 December in both seasons, respectively (Table 5). Moreover, planting L.R.-67 at 25 November and L.R.-62 at 25 December gave the maximum (108.67 days) and minimum (88.50 days) period to heading in both seasons, respectively (Table 6).

Table 5: Effect of sowing dates × N levels interaction on number of days to 50% heading in both seasons.

Treatments	N levels (kg/ha.)			
	120	240	120	240
	1 st season		2 nd season

*= Significant.

CONCLUSION

From the obtained results it can be concluded that number of days to 50% heading, flag leaf area, plant height, number of tillers/m² and straw yield per unit area were significantly increased with increasing N levels up to 240 kg N/ha. and at sowing on 25th November. Moreover, Gemmiza-9 performed better in turn of straw yield as compared with other genotypes.

MARKER ASSISTED BREEDING IN IMPROVING WHEAT FOR CLIMATE RESILIENCE

J.P. JAISWAL^{1*}, ANUPAMA SINGH¹, SAURABH BADONI, TIWARI, R¹, DEEPSHIKHA², EKHLAQUE AHMAD³, R.P. GANGWAR¹, DEVENDER SHARMA¹, N.C. GAHTYARI¹ AND PAWAN K. SINGH⁴

¹Department of Genetics & Plant Breeding and ²Department of Plant Pathology, G.B. Pant University of Agriculture & Technology, Pantnagar, India; ³Department of Genetics & Plant Breeding, BAU, Ranchi, ⁴International Centre for Maize and Wheat Improvement (CIMMYT), El Batan, Texcoco 56237, MEXICO.

Ever increasing threats of climate change to crop production and food security are being currently discussed globally. Wheat (*Triticum aestivum* L.) is one of the most important food crops worldwide, occupying largest cultivated area, and supplying 40% of food globally and 25% of calories for the developing world. Hence increase in its production and productivity is very much desired to meet the demand of ever increasing population. Five new pathotypes, namely, 110S119, 238S119, 110S84, 110S247 and 46S117 of stripe rust (*Puccinia striiformis*) reported in 2014 demands serious attention towards preparedness to fight against potential threat of this devastating pathogen. Due to change in climate, the severity of spot blotch (*Bipolaris sorokiniana*) incidence is increasing in North Western Plains Zone (NWPZ) of India where leaf and stripe rust, and powdery mildew were major diseases. Hence exotic germplasm obtained from CIMMYT, Mexico were screened under epiphytotic conditions and resistance lines were identified using gene linked markers. Considering the importance of yellow rust in Northern Hills Zone (NHZ) and yellow as well as brown rusts in North Western Plains Zone (NWPZ), two major yellow rust resistance genes, *Yr10* and *Yr15* and brown resistance genes *Lr19/Sr25*, *Lr24/Sr24* and *Lr34/Yr18* from the donor genotypes were mobilized in popular cultivars and elite genotypes. It is envisaged that marker-assisted deployment of major genes along with APR genes will confer durable rust resistance in wheat.

Key words : Germplasm, wheat leaf rust, stripe rust, spot blotch, microsatellite marker, marker-assisted backcrossing (MABC), Gene pyramiding

INTRODUCTION

Wheat is a source of food and livelihoods for over 1 billion people in developing countries. India with 98.61 million ton wheat production in 29.72 million hectare in 2017-18 is second largest producer of wheat in the world (ICAR-IIWBR, 2018). Wheat crop faces a variety of biotic and abiotic stresses during its life cycle. Particularly among biotic stresses, rusts (*Puccinia* spp) are destructive foliar disease of wheat (*Triticum aestivum* L.) and poses a substantial threat to food security worldwide. Rusts can cause yield losses from 10 to 70%, further reducing the quality of grain and forage (Chen, 2005). Where favourable conditions occur and susceptible varieties are grown, significant yield losses may incur.

It is anticipated that climate change will lead to enhanced problem of biotic as well as abiotic stresses. The three rusts, stripe (yellow), leaf (brown) and stem (black) of wheat can only survive on living plant material, with the dominant host being wheat. During the past decade a number of virulent strains of wheat rusts have emerged, causing global concerns to wheat production. In 2010 and 2013, a new, virulent strain of stripe rust on *Yr27* has caused severe outbreaks and losses in many countries in North and East Africa, the Near East and South Asia. Breakdown of *Yr9* resistance in mega wheat variety PBW 343 has become a matter of concern. There has been frequent breakdown of rust resistance in other popular wheat varieties in India in recent years. Earlier two races, 78S84 and 46S119 of stripe rust (*Puccinia striiformis*) were prevalent in hills and north western plains zone (NWPZ) of India, however five new pathotypes namely, 110S119, 238S119, 110S84, 110S247 and 46S117 were reported in 2014, which demands serious attention towards preparedness to fight against potential threat of this devastating pathogen.

Because rust fungi evolve rapidly, the main focus of our breeding is to emphasize resistance based on slow rusting, adult-plant resistance (APR) genes that individually have small to intermediate effects but high resistance level approaching near immunity, achieved by combining 4-5 of these genes (Singh et al., 2014). Apart from resistance durability, the main advantage of selecting additive, minor genes combinations is that selection can be done simultaneously with other traits in field conditions under high disease pressures.

Spot blotch, caused by fungus *Cochlibolus sativus* (anamorph *Bipolaris sorokiniana*), is currently the most important disease of wheat in eastern India (Gupta et al., 2017). The disease is particularly severe when high humidity stage and high temperatures occurs together at the late post-anthesis growth stages. As the wheat rusts remain under control, spot blotch has continued to dominate on nearly 9 m ha since Green Revolution (Joshi et al., 2007 and Singh et al., 2015). Being warm and humid, the eastern India is the hot spot for this disease where significant losses in wheat production are recurring features and estimated to be 15% on the average (Dubin and van Ginkel, 1991) affecting millions of resource-poor farmer. Several lines and varieties with moderate to adequate resistance have been developed and released, and diversity for resistance has increased in the improved CIMMYT germplasm (Singh et al., 2015). Severe infection may also reach to the spikes, resulting in less weight due to shriveled grains. therefore, analyzing spot blotch resistance along with its correlation with yield traits would help in identification of better donors for spot blotch resistance with higher yield to be used in breeding programme (Tiwari et al., 2016).

MARKER ASSISTED SELECTION: CHOICE OF MARKERS

Molecular tags- a prerequisite for marker assisted selection (MAS)- have been developed for many agronomic traits in several crop plants using different kinds of molecular markers. The essential requirements for molecular marker-aided selection in a plant breeding programme are: (1) marker(s) should cosegregate or be closely linked (1cM or less) with the desired trait; (2) an efficient means of screening large populations for the molecular markers should be available; and (3) the screening technique should have high reproducibility across laboratories, be economical to use and should be user friendly. Molecular markers are specially advantageous for agronomic traits that are otherwise difficult to score (Gupta et al., 1999). The choice of marker system to be used for the detection of DNA polymorphism, depends first on the objective of study and the needs dictated by its specific application, and second on the facilities and skills available in a laboratory. Therefore, a comparative study of different technologies may be helpful in making a choice of suitable marker.

Gupta et al. (1999) compared the advantages and disadvantages associated with the use of different marker systems so that one may choose a suitable marker technology, for a specific purpose, such as plant breeding, DNA fingerprinting, genetic diversity analysis and comparative mapping. It should be recognized that different marker systems may be suitable for different purposes. For example, it has been shown that microsatellite markers are codominant and, relative to all other marker types, have high information content (estimated as either the polymorphic information content or genetic diversity index or expected heterozygosity). However, the very high cost of their development restricts their uses in many laboratories. However, the availability of large number of microsatellite primer pairs in bread wheat and the extensive molecular genetic maps based on these microsatellites overcame this barrier has accelerated their use even in small laboratories. In addition, the locus specificity and high level of polymorphism associated with microsatellites make them the marker system of choice for molecular marker-aided selection in practical plant breeding.

Use of molecular markers has emerged as a powerful and efficient approach to complement traditional plant breeding for improving crops. An array of molecular markers are now available that include RFLP that is based on Southern blot hybridization and, RAPD, ISSR, SSR and STS are based on polymerase chain reaction. The AFLP and CAPS markers are the other PCR based markers involving pre and post amplification restriction digestion, respectively. The most recent marker system is single nucleotide polymorphism (SNP) that utilizes the vast DNA sequence resources available in different crop species. Each of these markers has its own strengths and limitations. Markers are being used in several different aspects of crop improvement including estimation of genetic diversity, construction of high density genome maps, mapping and tagging of genes, map-based isolation of genes and marker assisted selection (MAS). MAS is carried out for transferring target gene(s) from one genetic background to another using tightly linked markers (foreground selection). MAS is also carried out to quickly recover recurrent parent genome in backcross breeding using a large number of either random or mapped markers having whole genome coverage (background selection). Hence, MAS requires markers tightly linked to the genes for the target traits as well as high-density genome maps in crops of interest. This condition is not fulfilled in all crops and traits. MAS has been effectively employed in pyramiding identified genes involving short breeding cycles through background and foreground selection thereby adding resistance to established cultivars of each crop (Prabhu et al., 2009).

MARKER VALIDATION

Before using the molecular markers in actual plant breeding, it is necessary to undertake studies on marker validation, a process of examining the behaviour of markers and the associated polymorphism in different genetic backgrounds. The validity of a molecular marker linked with any trait should be examined in other crosses, since, for a marker to be useful in breeding programmes, it needs to detect the polymorphism in different crosses. For example, markers identified in one cross as being linked to protein content need to be tested in other crosses to determine if the alleles associated with high and low protein contents in two genotypes involved in the original single cross used for marker development, are also associated with similar phenotypes involved in other crosses.

Marker validation involves: (1) identification of potential markers from available research; (2) identification of the genetic material for the appropriate breeding programmes; (3) examination of the effectiveness of the marker/trait linkage in the breeding material identified; (4) critical discussion of results, and suggestions from the plant breeders to decide on the validation of the particular marker-trait combination. However, it may be more difficult to conduct marker validation for quantitative traits where there is major genotype-environment interaction, so that the effect of a QTL in a specific environment is impossible to predict, since different loci may interact differently with different environments. The difficulty may be overcome by identification of more and more QTL linked with independent molecular markers followed by mapping of the QTL identified and subjecting them to interval mapping (Gupta et al. 1999).

Gene pyramiding for durable resistance: Role of molecular markers

The term gene pyramiding in plant breeding is used to signify the activity of building into one variety more than one gene for a character so that the expression of the character is enhanced. Conventionally, breeding plants with resistance against a specific disease requires the identification of resistant parents, which are then crossed with agronomically acceptable but susceptible parents. A program of backcrossing to the susceptible parent and selection of resistant phenotypes leads to the production of plants that are similar to the susceptible parent but have the required resistance. Typically, this process takes 10 or

more years, and by this time, the pathogen has evolved a variant that is not recognized by the improved cultivar, leading to susceptibility. To overcome this, molecular markers play an important role to improve the efficiency and precision of conventional plant breeding via marker-assisted selection (MAS). In majority of the MAS programmes, marker assisted back crossing (MABC) has been deployed which includes marker assisted foreground selection along with phenotypic selection to identify plants possessing desirable genes in segregating populations and background selection, utilizing the polymorphic markers to ensure the sufficient recurrent parent genome (RPG) recovery. Breeding of resistant varieties is an effective approach to eliminate the use of fungicides and minimize crop losses due to rust diseases. Therefore, breeding varieties with multiple diseases resistance is essential and also most economical way to manage them. Molecular markers have emerged as a powerful tool for the precise transfer of genes from donor to recipients and it is becoming integral part of classical plant breeding. Molecular markers help precise introgression of gene of interest on one hand and screening of sources of resistance on the other hand (Gupta et al., 2010, Tomar et al., 2014, Prabhu et al. 2009).

MATERIALS AND METHODS

Resistance evaluation in field conditions and confirming the resistance with gene linked markers

The investigations were carried out at the Department of Genetics & Plant Breeding, G. B. Pant University of Agriculture and Technology, Pantnagar, India. Five stripe rust pathotypes were selected for screening for race-specific resistance namely 46S119, 78S84, 47S102, 46S102, and 47S103. Out of them, 46S119, 78S84 were highly prevalent stripe rust pathotypes with in the Indo-gangatic region and within Indian subcontinent.

Germplasm screening for rust resistance

A total of 440 germplasm obtained from National Bureau of Plant Genetic Resources (NBPGR), New Delhi, were used to evaluate the accessions for resistance towards the stripe rust in season 2013-14 and 2014-15. Resistant checks including Avocet/Yr5, Avocet/Yr10, and Avocet/Yr15 were used in the field trial. The plots were surrounded by susceptible spring wheat Agra local as a spreader of rust inoculum naturally. In addition, to increase the inoculums load, artificial inoculation was performed with the virulent races 78S84 and 46S119 of stripe rust. Inoculation and evaluation of rust disease were performed at the seedling stage as well as the adult plant stage. The recommended scoring method was followed to undertake the pathological analysis. In order to test the adult-plant stage, field tests were considered having adult plant resistance (APR); those that had a high infection type (moderately resistant (MR)-moderately susceptible (MS) type reaction) but possessed low disease severity (<30%) in the field tests at the adult-plant stage were measured showing durable/slow-rusting (SR). Genotypes were selected on the basis of two consecutive years (2013-14 and 2014-15) and pathological studies were further subjected to molecular marker analysis (Table 1) to evaluate the source of resistance present by following narrow down methodology (Fig. 1).

MARKER ASSISTED GENE TRANSFER FOR RUST RESISTANCE

The high yielding wheat varieties, UP 2338, UP 2382 and 7UP 2572 were taken as recipient parents to improve the rust resistance using the donors Avocet/Yr10 and Avocet/Yr15 for Yr10 and Yr15, respectively, and the APR gene Lr34/Yr18 with UP 2425. Gene and marker information is given in Table 1.

Table 1. Targeted genes and linked markers

Gene/ trait	Gene linked marker	Primer sequence	Size of fragment (bp)	Reference

Fig. 1. Schematic diagram of narrow down methodology followed to unveil the source of stripe rust resistance in 440 diverse germplasm set. These screened genotypes were ultimately subjected to molecular genotyping for race-specific major genes viz. Yr5, Yr10, Yr15, and non-race specific durable resistance gene Lr23/Yr18 using tightly linked markers (Badoni et al., 2017).

GERMPLASM SCREENING FOR SPOT BLOTCH RESISTANCE

Simultaneously to identify resistance sources for spot blotch from a set of exotic germplasm received from International Centre for Maize and Wheat Improvement (CIMMYT), Mexico, accessions were screened under epiphytotic conditions [Chaurasia et al., (1999)]. Disease assessment was done by recording disease severity (%) displayed by all the leaves of each row was recorded at three different growth stages (GS), viz., GS 63 (beginning of anthesis to half complete), GS 69 (anthesis complete) and GS 77 (late milking). The area under disease progress curve (AUDPC) based on disease severity (GS63, GS69 and GS77) over time was calculated (Shaner and Finney, 1977).

The resistance was confirmed using the gene linked SSR markers. *Xgwm148* (Kumar et al., 2010) and STS marker, *csLV34* (Lagudah et al., 2006) linked to spot blotch resistance QTL were used to confirm the resistance shown by germplasm accessions at molecular level. Twenty two out of 200 accessions showing high resistance under epiphytotic conditions were subjected to molecular marker analysis. One each resistant check (Chirya 3) and susceptible check (Ciano T 79) was also used along with the resistant accessions for comparison.

MARKER VALIDATION AND EVALUATION UNDER ARTIFICIAL EPIPHYTIC CONDITION

First of all markers were validated in the background of selected donor genotypes. Marker assisted foreground selection was employed to identify plants possessing desirable genes in segregating populations. The segregating generation progenies were artificially inoculated with prevalent pathotypes of yellow rust. The inoculum of rust pathotypes was provided by ICAR-Indian Institute of Wheat & Barley Research Institute, Regional Research Station, Flowerdale, Shimla. Stringent phenotypic selection for faster recovery of the recurrent parent genome was exercised.

RESULTS

Marker assisted breeding for rust resistance

Validation of genes in the background of respective donors

Validation of resistance genes, Yr10, Yr15, Lr19/S25, Lr24/Sr24 and Lr34/Yr18 in the background of respective donors, Avocet/Yr10, Avocet/Yr15, FLW 8, FLW 21 and UP 2425 was done using different microsatellite markers. The amplification using the marker *Xpsp 3000* has shown the desired allele for Yr10 with product size of 260bp in the donor, and in the recipient parent presence of two bands of ~210bp and 290bp was observed. For Yr15 the marker *Xgwm 273* shows the presence of desired allele with product size of 165bp in the donor and in the recipient no band was observed.

Foreground selection for the presence of genes in F_1 and backcross populations

Foreground selection was attempted using the gene linked markers *Xpsp 3000*, *Xgwm273* and *csLV34* for the genes, Yr10, Yr15 and Lr34/Yr18, respectively. The lines showing positive for the genes were tagged before flowering and

backcross was attempted to generate BC₁F₁, BC₂F₂ and BC₃F₃ generations. In each generation sufficient disease pressure was created using virulent races of brown and yellow rusts. A representative gel showing the presence of Yr15 in BC₁F₁ has been shown in Fig. 2.

Fig. 2: Representative gel image of foreground selection for Yr15 in BC₁F₁ generation

M- 100 bp step up ladder, P₁- UP 2338, P₂- Avocet-Yr15, 1-13: progeny of BC₁F₁ generation, genotype no. 1, 4, 7 and 13 shows the presence of donor allele of 165 bp

Evaluation of selected homozygous breeding lines for agronomic performance

On the basis of resistance to stripe rust at phenotypic as well as at molecular level, eleven lines were selected from 56 IPS. These all selected lines showed variable expression for all the agronomic traits as well as for disease severity. All the traits viz., plant height, spike length, number of spikelets per spike, length of flag leaf and width of flag leaf was comparable with recurrent parent UP 2338, while disease severity was comparable with the donor parent Avocet-Yr15. Data on thousand grain weight of ten lines, out of eleven selected lines showed better expression than that of recurrent parent (with disease pressure). Data on disease severity and response of these ten selected lines is given in Table 2.

Table 2: Disease severity and disease response of selected improved lines in the background of UP 2338 (Singh et al., 2018)

Cross combination	Disease severity (%)	Disease response
UP 2338 x Avocet-Yr15		
1	Trace	Resistant (tR)
2	Trace	Resistant (tR)
3	Trace	Resistant (tR)
4	10	Moderately resistant (10MR)
5	5	Resistant (5R)
6	Trace	Resistant (tR)
7	Trace	Resistant (tR)
8	5	Resistant (5R)
9	5	Moderately resistant (5MR)

5	5	Resistant (5R)
UP 2338 x FLW 21		
1	5	Resistant (5R)
2	5	Moderately resistant (5MR)
3	Trace	Resistant (tR)
4	Trace	Resistant (tR)
5	Trace	Resistant (tR)
6	Trace	Resistant (tR)
UP 2338 (Recipient)	80	Susceptible (S)
Avocet-Yr15 (Donor)	0	No sporulation
FLW 8 (Donor)	0	No sporulation
FLW 21 (Donor)	0	No sporulation

Background selection

Background selection was performed using 57 polymorphic SSR markers for progenies of *Lr19/Sr25* gene and 48 SSR markers for progenies of *Lr24/Sr24* gene which were distributed over all the 21 chromosomes. The recovery of the genome of recipient parent was evaluated in all foreground positive plants available in backcrossed generation namely, BC₂F₁, BC₃F₂ and BC₃F₃ except for BC₃F₁ generation. Background selections for recipient parent UP 2338 provided the RPG recovery with the average of 94.30% in a range of 85.25% to 96.45% for *Lr19/Sr25* and for *Lr24/Sr24* RPG recovery was found with the average of 94.65% in a range of 84.25 % to 96.45%.

Phenotypic evaluation for spot blotch resistance

The spot blotch epidemics developed well in field trials. Germplasm accessions were highly variable for disease severity (Fig.3) as AUDPC value was calculated to screen the 200 germplasm accessions against spot blotch (*Bipolaris sorokiniana*) severity in the field under epiphytotic conditions. Out of 200 accessions, 17 accessions were observed highly resistant, 7 resistant, 87 moderately resistant, 3 highly susceptible and 86 accessions were observed moderately susceptible (Table 3).

Molecular evaluation for spot blotch resistance

Both the markers *Xgwm148* and *csLV34* have shown polymorphism between the resistant (Chirya 3) and susceptible checks (Ciano T79) and the marker *Xgwm148* with a product size of 165bp differentiated 9 out of 22 accessions (Fig.4). Similarly, the marker *csLV34* with a product size of 160bp differentiated 10 out of 22 accessions (Fig.5). Three accessions shown in lane number 11, 17 and 19 namely, accessions no. SKAUZ/KS91WGRC11//SKAUZ,CH/TH.CU

//GLEN/3/ALD/PVN/4/CS/LE.RA//2*CS/3/CNO79 and BCN//YUK/AE.SQARROSA (434) respectively were, found positive for both the markers.

Table 3: AUDPC values of 200 germplasm accessions

Spot blotch resistant/ susceptible	Total no. of accessions	AUDPC range
Highly resistant	17	0
Moderately resistant	87	568.5-1248
Resistant	7	157.5-496
Moderately susceptible	86	1256.5-1912.5
susceptible	3	2029.5-2346

AUDPC value of checks: Chirya 3 - 454.5 (R), Francolin- 914.5 (MR), Sonalika- 2267 (S), Ciano T 79- 1891.5 (MS)

AUDPC value: < 500= resistant (R), 500-1250= moderately resistant (MR), 1250-2000= moderately susceptible (MS), >2000= susceptible (S), 0.00= Highly resistant

Accession No. 6, 8, 9, 10, 11, 15, 16, 17, 18, 19 and 22 showing the presence of Lr34/Yr18.

DISCUSSION

Rusts are the most devastating fungal diseases in wheat worldwide, which can primarily be managed through resistance breeding as chemical control is costly and not eco-friendly. However, cyclic breakdown of the resistance genes due to evolution of new pathogenic races, demands for constant identification of new genes for resistance. Pyramiding of two or more genes can help to improve the durability of rust resistance but it is possible only if closely linked DNA markers are available (Vinod et al., 2010). With the advent of DNA markers it has now become possible to precisely transfer the desirable genes from unadapted germplasm to elite lines with minimum or no linkage drag.

In the present study, we successfully introgressed three rust resistance genes viz., *Yr15*, *Lr19/Sr25* and *Lr24/Sr24* into a popular wheat variety UP 2338 through marker assisted backcross breeding. Crosses were attempted in the lines of BC₂F₂ generations for the pyramiding of stripe rust (*Yr15*) and leaf rust (*Lr19* and *Lr24*) resistance genes in the background of the recurrent parent UP 2338. The cross seeds (F₁s) were raised and positive plants for both the genes were selected, harvested and forwarded for further evaluation. MAS also has been successfully implemented to introgress the gene through marker assisted backcrossing (MAB) and pyramid major genes/QTL through marker assisted pyramiding (MAP) for different traits in wheat (Sivasamy et al., 2009; Chhuneja et al., 2011; Kumar et al., 2011; Singh et al., 2018). Agronomic performance of selected introgressed plants was comparable to recipient parent which shows that phenotypic selection along with markers assisted background selection led to maximum genome recovery of recipient parent in the present study. Background analysis exercised through phenotypic evaluation is reported to be useful in efficient recovery of the RPG (Singh et al., 2013; Singh et al., 2018).

Spot blotch is a significant production constraint in the Northern Eastern Plain Zone of India, and hence, it was considered to be worthwhile to screen the CIMMYT germplasm to identify resistance accessions, which could be of help in developing spot blotch resistance wheat varieties. Lr34 conditions resistance to leaf rust, but it has been established that, via either pleiotropy or through linkage to a spot blotch resistance gene, its presence simultaneously gives a significant level of protection against the spot blotch pathogen (Lillemo et al., 2013). Because the Lr34 is tightly linked with LTN, this phenotypic marker can be used to identify plants with Lr34.

Vasistha et al. (2017) reported that the mean AUDPC for spot blotch in eleven BC₃F₅ homozygous lines carrying Lr34 gene was substantially lower than that of recurrent HUW510 (susceptible to spot blotch). Grain yield was also higher in the Lr34 lines. This study demonstrated that the leaf rust resistance gene Lr34 can be successfully introgressed into popular wheat cultivar using MAS for enhancing resistance against spot blotch. Exploration of germplasm resources for the identification of genes conferring resistance to different diseases using the molecular markers should be a continuous effort (Badoni et al., 2017; Devi et al., 2016; Jaiswal et al., 2015; Jaiswal et al., 2016; Talha et al., 2016).

CONCLUSION

The methodology adopted in the study successfully demonstrated as proof of concept of the efficient, and precise methodology involved in screening of a large set germplasm. Exploration of germplasm resources for the identification of genes conferring resistance to different diseases using the molecular markers should be a continuous effort so that elite germplasm could be properly tagged and eventually serve as a valuable genetic resource. Similarly transfer and pyramiding of multiple genes for resistance through marker assisted back crossing (MAB) has been successfully resulted in the

improvement of popular varieties. The outcome may be potentially helpful for breeders by assisting them to rapidly incorporate the combination of race-specific and non-specific genes into widely adapted wheat cultivars through marker-assisted pyramiding approaches for minimizing the loss caused due to rust epidemics and other diseases of importance in wheat.

ACKNOWLEDGEMENT

The authors pose sincere thanks to DBT, Govt. of India for funding through Accelerated Crop Improvement Project, CIMMYT, Mexico for financial support from Seeds of Discovery (Seed 2012-021) project, and Director, Experiment Station, GBPUAT, Pantnagar for providing logistics for carrying out the investigation.

POTATO FOR FOOD AND NUTRITIONAL SECURITY: INDIAN PERSPECTIVE**MANOJ KUMAR, BANDANA AND ANUJ BHATNAGAR***ICAR-Central Potato Research Institute Campus, Modipuram, Meerut-250110*

Potato (*Solanum tuberosum* L.) is one of the most important non-cereal food crop worldwide and is prominently called as king of vegetables in India. High photosynthetic efficiency with high harvest index and flexible growth period make this crop amongst top producer of edible dry matter per unit area and time. Potato, besides being high in starch/ carbohydrate, biologically superior protein, rich in minerals and also some vitamins has very important role in ensuring food and nutritional security for ever growing world population and rightly been identified as food for future by the FAO. World population is likely to touch 9.7 billion by 2050 with its 17% share in India (1.65 billion) this crop has to play key role in global sustainable food system producing more energy and dry matter from less land as compared to rice, wheat and maize. Additional virtue of potato is it has negligible fat with substantial amount of vitamins. Potato is one of the food crops of the world that alone combines the desirable characteristics of high yield, low cost and a nutritious and palatable food. Potato has multiple uses as staple food, vegetable and delicious processed items throughout the world.

India stands second in potato, producing about 48.6 m tonnes from 2.01 m h after China. True potential of this crop was realized only in post-independence India with increase in area by 9 times, production by 30 times and productivity by 3.3 times. Potato from its meagre area has great potential to play a very significant role in rural poverty alleviation and food and nutritional security in Indian economy. This crop traditionally a temperate crop has been sub-tropicalized by the great collective efforts of researchers and farmers of the country in the leadership of ICAR-Central Potato Research Institute (CPRI), Shimla. The country has about 60 potato varieties as national and Institute release with its suitability in various regions and purpose. These varieties may be grouped as short, medium, long durations, processing purpose, red skinned, nutritionally superior potatoes, etc. About 4000 (and increasing) germplasm repository provides strong source base for creation of large variability for strong breeding programme. Region specific potato production sound agro-technique including nutrient and water management developed and cropping systems identified has played great role in increasing productivity as well as horizontal expansion of this crop. Digital soil maps of potato growing area, validated models, decision support systems and expert systems are in place and being improved further to progress towards precision cultivation of crop. Late blight the most dreaded disease has almost been mastered with well validated prediction model and efficient management schedule in place. Integrated management for all major pests and diseases has already been included in recommendations in all major potato growing regions. Viral diseases are main culprit of vegetatively cultivated potato for degeneration of seed. Hence, it is important to use healthy seed for sustainable and economic production of potato. Since last five decades strong potato seed production programme of the country based on elimination of viruses using advanced serological and diagnostic technique, rouging, and growing crop in vector free window as well as, conventional seed production technology based on "seed plot technique" has contributed immensely in bringing potato revolution and saving huge foreign exchequer. CPRI has developed state of art high-tech seed multiplication system based on tissue culture and aeroponic. Adoption of seed production systems developed by the institute has led to opening of more than 20 tissue culture production units throughout the country. Several Government/Private seed producing organizations procure virus-free in vitro mother cultures of important notified and released potato varieties every year from ICAR-CPRI, Shimla for further multiplication in their high-tech seed production programmes. The latest hi-tech seed production system standardized by the institute is based on the concept of soil-less, aeroponic technology. The aeroponic system of seed production has the potential

to revolutionize potato seed sector has been commercialized to 14 firms of the country. Each firm is licensed to produce 10 lakh mini tubers by aeroponic system. Even if each firm is operating at half of its potential, about 6.5 million mini tubers are currently being produced by those firms.

With the development of potato processing varieties (namely Kufri Chipsona-1, Kufri Chipsona-2 Kufri Chipsona-3, Kufri Chipsona-4, Kufri Frysona and Kufri Himsona) along with its production, post-harvest and processing technologies, now about 7 % of our national production is going for processing. It can be of great of help in solving the issue of glut and increase the diversified use of potato. The availability of quality raw material of these varieties and standardization of storage techniques for processing potatoes at 10-12°C with sprout suppressant CIPC [Isopropyl N-3-chlorophenyl carbamate] has also changed the entire scenario of potato utilization in India within a short span of last 10 years. Since last many years it has been observed that the economic growth of the country has too accelerated potato consumption, which is expected to continue for processed, ready to eat convenience food, which has led to diversification in potato consumption and utilization.

Despite such an impressive achievements, there are still many challenges and emerging problems which need to be addressed in coming decades. CPRI Vision 2050, after accounting for rapid growth of potato processing due to fast economic development of the country, lower proportionate growth rate of seed demand, rise in per capita consumption of fresh potato (future role of potato in food security and fast economic development) and as a result of ongoing efforts to lower post-harvest losses, envisage, the estimated demand of potatoes in 2050 about 122 million t. In addition demand of another 3 million t during 2050 is assigned to potato starch industry, animal feed, export of seed potato and processed potato products. Hence, we would require potato production of about 125 million t in 2050 in our country at an ACGRs of 3.2%. To achieve this production target it is envisaged that area under this crop has to be increased from present 2 m h to 3.62m h with increasing productivity level 23 to 34.51t/ha. These production and yield targets has to be achieved against odds of changing climate, increase occurrences of weather extremities, reducing availability of good quality water, increasing demands and awareness of healthy food, with the additional goals of increasing environmental sustainability and economic viability. There are challenges to meet international standard to increase export share of our production following good agricultural practices (GAP). Our research system is well tuned to develop need based technology working in collaboration with farmers and other sectors, however, favourable policy support and infrastructure growth is must to sustain the momentum.

CONSTRAINS AND STRATEGIES FOR DOUBLING THE INDIAN FARMERS INCOMES BY 2022-AN OVERVIEW**RAM JI LAL, RASHMI NIGAM AND JOGINDER SINGH***Ex. Principal Scientist & HOD, Division of Crop Protection**ICAR-Indian Institute of Sugarcane Research Lucknow-226 002**Department of Plant Pathology, J. V. College, Baraut, Baghpat, UP**Department of Horticulture, J. V. College, Baraut, Baghpat, UP*

In India, agriculture is the largest private enterprise (>10 crore farm holdings), has been and will continue to be the lifeline of the Indian economy at least in the foreseeable future. It contributes nearly 17% to National GDP, sustains livelihood of about two third of the population, accounts for 52% of the National workforce and forms the backbone of the agro-based industry. In global terms, India today has: 16 % of human population, 15% of farm animal population, 2% of geographical area, 1% of rainfall, 0.5 % of forests, and 0.5 % of grazing land.

India through modern agricultural technologies has moved from an era of chronic food shortage and “begging bowl” to a level of food self-sufficiency, buffer stocks and even food exports. At present the productivity gains are nearly 3.5 times in food grains, 1.6 times in fruits, 2.1 times in vegetables, 5 times in fish, 1.8 times in milk, and 4.8 times in egg production., respectively. Besides, agriculture is a social sector where non-trading concerns like food and nutritional security, employment and income generation, poverty elevation, gender equality, ecology and environment play a significant role. India’s population is expected to be around 1.5 billion by 2030 AD at the present compound growth rate of 1.6 per cent per annum. The country will required to produce an additional 5-6 million tonnes of food grains annually to meet the food requirements. Therefore, the country must continue to produce more food and other agricultural commodities per unit of land, water, energy and time to feed the increasing population. In this process, it has to be ensured that there is no damage to the ecological foundation of agriculture, such as land, water, forest, biodiversity and the atmosphere.

However, the diverse changes and constraints as growing population, increasing food, feed and fodder needs, natural resource degradation, climate change, appearance of new threatening insect-pests and diseases, slow growth of farm income and new global trade regulations demand a paradigm shift in formulating the National Agricultural Research Programmes (NARP) to conserve natural resources and bio-diversity for achieving food security besides maintaining the ecological balance for sustainable agriculture.

Keeping above in mind, one of the major policy initiatives of the National Democratic Alliance (NDA) government is that of doubling farmers incomes by 2022 to feed the ever growing population. There has been agrarian distress in the sector for the last two decades. Therefore, there is need to focus on farmers income instead of production or the growth rate in agriculture. Official recognition of the distress and the agrarian crises came in the form of NSSO (National Sample Survey Office) survey in 2003, which reported that 40% of Indian farmers disliked the farming as a profession due to its low profits, high risk, and the lack of social status and, therefore, would like to leave it at the first opportunity (Agarwal and Agarwal, 2017).

They are continuing farming in the absence of opportunities outside agriculture. Furthermore, there are cast-wise differences among farmers in terms of their interest in farming; the higher casts seem to be more reluctant with farming than Scheduled Caste (SC) and Scheduled Tribe (ST) farmers. Among the SC and STs, the disliking for farming diminishes with increase in landholding size and increases in the case of other casts (Bithal *et al.*, 2015). The need to focus on farmers income also indicates from the fact that a very large population of the farming households in most of the central and eastern states (23.0% -45.0%) live below the poverty line (BPL), higher than the national average (22.5%). The proportion of BPL farming households (17.5%-22.5%) even in some of the so called agriculturally progressive states such as Gujarat, Karnataka, Maharashtra, and Tamil Nadu, is close to the National average. Further, the gap between farm and non-farm incomes has grown over the decades, from a ratio of 1:30 in the mid-1980s to 1:4.08 in the middle of last decade, and 1:3.12 in 2011-2012 (Chand, 2017).

There has been much debate for the last one year about the definition of the farmer’s income and the time frame for doubling it. If it is doubling of the real incomes of farmers then it is an important and challenging goal to achieve it in five to seven years because of the following reasons. (i) low and non-remunerative Maximum Support Prices (MSPs) (ii) non-remunerative price in the market (iii) the low share of farmers in the consumer rupee (iv) poor penetration of crop insurance (v) high and increasing input costs, and (vi) the absence of market infrastructure. They also cite modest growth in the past compared to the 12% annual figure needed for doubling the farmer’s income in nominal terms, which works out to be an annual growth of 20-30% to double the farmers income in real terms.

It is estimated that doubling incomes in nominal terms requires six years, and in real terms 13 years, and it is going to take longer time frames in both respects for marginal and small farmers. Further, it would need varied time frames across different state-level growth rates of farmers household incomes—which vary from 6.7% in West Bengal to 17.5% in Haryana in nominal terms, with the average for India being 11.8% - and on the absolute levels of farmer household income (Satyasai

and Mehrotra, 2016). It is estimated that farmer's incomes can be increased by 75% in seven years, and that it would take 10 years to double the same (Chand, 2017).

Annual income per farmer has increased from Rs. 12365/- in 1993-94 to Rs. 1,20,193/- by 2015-16, at current prices. However, at real prices, the increase has been from Rs.21,110/- to Rs. 44,027/- during this period. This shows that farmers average real incomes doubled only after a period of 22 years. Even the total farm income of all farmers at real prices just about doubled during this period, from Rs. 3.0 lakh crore (Rs. 3 trillion) to Rs. 6.0 lakh crore (Rs. 6 trillion). This works out to a growth rate of 3.4% a year per farmer and 3.13 for total farmer income over the period (Chand, 2017).

The recent survey conducted by the NABARD in the country indicate that the annual income of the farmers is increasing at the rate of 12% per annum whereas, there is requirement of only 10.4% growth rate per annum to double the farmers income. About 48% farmer's family resides in the village. During 2015-16 the, per family income was 1.07 lakh which they obtained from farming, animal husbandry and other agricultural activities while, there income was Rs. 77,110/- per family during 2012-13. Out of 34 States and Union Territories, in 19 the growth rate of income was 15% and it was 10.5% in the remaining states. At country level, overall growth rate was 12.0%. The report also indicated that about 52% farmers of the country are in debt. The committee further indicated that in growth rate of income, the southern states are much ahead than Punjab, Haryana and Western Uttar Pradesh. It also includes West Bengal, Odessa, Bihar, Jharkhand and Eastern Uttar Pradesh. Therefore, there is more probability for increasing the growth rates in these states.

Dr Mahapatra, Director General, Indian Council of Agriculture (ICAR) and Secretary Department of Agricultural Research and Education (DARE) in a 2 days conference held in New Delhi said that in the country only 5.0% youths adopt agriculture as a profession due to absence of any other source of income. He further emphasized that this is a very serious issue in the field of agriculture. Therefore, the Government of India is immediately launching a scheme "Abhyas" to attract the science graduates to takeup agriculture. The science graduates will be given six months training free of cost under said scheme and after that they can start their own agricultural clinics, soil testing labs or any other related types of business for the benefit of the farmers. The banks will also provide loans free of cost on subsidised rates to such youths (*Danik Jagaran* dated 31st August, 2018).

The central government has tremendously increased the Maximum Support Price (MSP) of various crops against previous year as mentioned in Table-1.

Table-1: Maximum Support Price (MSP) of various crops fixed by the central government

Crop	Production Cost/ quintal (Rs.)	MSP */Q (Rs.)	Increase as against previous year (Rs.)	Percent benefit in comparison to cost of cultivation
Rice (Ordinary)	1166.00	1750.00	200.00	50.-09
Rice (Grade-A)	-	1770.00	180.00	-
Jowar (Hybrid)	1619.00	2430.00	730.00	50.09
Bajra	990.00	1950.00	525.00	96.97
Maize	1131.00	1700.00	275.00	50.31
Arhar (Tur)	3432.00	5675.00	225.00	65.36
Moong	4650.00	6975.00	1400.00	50.00
Urd	3438.00	5600.00	200.00	62.89
Groundnut	3260.00	4890.00	440.00	50.00
Sunflower	3598.00	5388.00	1288.00	50.01
Soyabean	2266.00	3399.00	349.00	50.01
Til	4166.00	6249.00	949.00	50.01

*: MSP (Maximum Support Price); Source: *Danik Jagaran* dated 25th August, 2018

Road maps prepared by different states for doubling the farmers incomes:

Some of the states, like Madhya Pradesh, Chhattisgarh and Uttar Pradesh have already prepared their road maps for doubling farmers incomes.

The Government of Madhya Pradesh in 2016 has estimated the contribution of various sources of increase in incomes: increase in yield would contribute 30%, agricultural diversification 20%, reduction in input costs and better prices 15% each, with rest coming from an expansion in area under cultivation (14%) and a reduction in the post harvest losses (6%). Regarding increases in yields, the gap between present and attainable yields was found to be as high as 43%-131% across different crops i.e. coarse grains, pulses and oil seeds.

The state government has set up a task force on the issue of doubling farmers incomes and has appointed an advisory committee of 51 progressive farmers under the chairmanship of the Ministry of Agriculture. Fifty one districts have prepared their own road maps for this purpose and 55,000 villages are also working toward preparing such road maps, which would be presented at *panchayats* specially set up for agriculture at the time of the *Pradhan Mantri Krishi Mahotsav*. District

irrigation plans have been prepared under the Pradhan Mantri Krishi Sicahayee Yojna (PMKSY). Half a million temporary agricultural pumps are made permanent with an allocation of Rs. 5,000/- crore.

It has also identified 19 constraints in order to double farmers incomes. These include: increased irrigation from public recourses, additional electricity supply for agriculture, interest-free crop-loans, expansion of agricultural area, encouraging mechanization, agricultural diversification, expansion of modern seeds, soil health management, new channels of agricultural technology, extension, farmer-producer company organization, expansion of the food processing sector, encouragement to organic farming, management of natural risk in agriculture, expansion of agricultural storage capacity, better organization of agricultural markets, animal husbandry, fisheries, silk, bamboo and agro-forestry production, and institutional structures for achieving the objective. So far 142 farmer-producer companies have been set up and 300 more such companies are planned by 2021. The institutional structures include an agriculture cabinet, a separate agriculture budget, a task force for the agricultural sector, a farmers commission for agricultural development and farmer well being, and micro irrigation and agro-forestry missions. It is estimated that yield and production-related efforts would lead to 70% additional farmer income with the remaining 30% coming equally from cost reduction, higher prices and reduced economic losses (Government of M.P.).

The Government of Chhattisgarh has decided to focus on 7 areas to increase farmers income: agricultural development of Adivasi farmers, reducing the cost of cultivation, increase in yields, improving the market infrastructure, storage and processing facilities, development of irrigation, agricultural diversification, and better agricultural extension system. It estimates that the Union Governments soil health scheme would lead to a saving of 10% on fertilizers and contribute to a 5% increase in yields. It also plans to use Mahatma Gandhi National Rural Employment Scheme (MANREGA) to recharge 4,50,000 irrigation wells and raise the yield of rice, maize, pulses and other oil seeds. It proposes to set up at least 20 farmer-producer companies in each district and bring half the number of farmer's under a crop insurance scheme. The expected reduction in cost of production through various means is estimated to be 5-15%. Production would increase 15-30%, price realization 10-20%, cropping intensity 15-30% and off-farm resources 5-30%, with extension contributing 5-20%. Thus income can increase between 55% and 155% over the next 7 year

It further details crop-specific increases in income, which vary from 5-35% across crops due to seed replacement, 10% due to bio-fertilizers, and 5-15% through mechanical sowing. It is also expected that a 15% increase in incomes will come from the use of check dams and small irrigation ponds each. The area under horticulture has been targeted to increase by more than 60%, and the number of onion storage structures to rise to 100% from 12 at present. The area under protected cultivation is expected to be more than double during this period. Similarly increases in income from animal husbandry are estimated, with 30% due to rise in yields, and 10% each from reduced cost of production, price increase, better risk management, and the expansion of the government schemes. The major activities for achieving the higher income targets include: an increase in seed replacement rate of maize, and lentils, expansion in issuing soil health cards, the promotion of the system of rice intensification, drip and sprinkler irrigation, and replacement of short term loans. The other major steps include linking up of markets with the National Agricultural Market, e-NAM, expanding cold storage capacity, building green/shed net houses, organizing new dairy cooperative societies, expanding bulk milk cooler and milk-chilling centre capacities, cage culture in fisheries, and agri-clinics and agricultural business centres, and doubling the production of lac (Dept. of Agriculture and Food Processing, 2017).

The Government of Uttar Pradesh is also taking solid steps for doubling the farmers income by 2022. For this, apart from farming it is also concentrating their efforts in horticulture, animal husbandry besides agriculture, management of natural resources through agricultural diversification by encouraging the farmers for the balance use of fertilizers on the basis of soil health card and increasing the irrigation facilities in low rainfall areas. In addition, the government is also taking steps for food processing with the help of private entrepreneurs, providing higher price of farmer's produce through simple and quick disposal scheme and bringing maximum farmers under crop insurance scheme.

It has set up the target for the production of 86.38 lakh Mt. ton food by 2022. Therefore, the government is forcing farmers to adopt soil health scheme for the judicious and balance use of fertilizers to achieve this target. The government has also set up a "Krasak Sambridhi Ayog" to double the farmer's income by 2022. The Hon'ble Chief Minister is its President, State Agriculture Minister, Prof. Ramesh Chandra (Member of NITI Ayog), are its Vice Presidents, Agriculture Production Commissioner (APC) and Chief Secretary are its members. It has also nominated Agricultural Scientists, Special Secretaries of various departments besides representatives from co-operative sectors to advise the government for doubling the farmer's incomes by 2022. The "Krasak Sambridhi Ayog" has set up to consider and recommend the government on the following five points for doubling the farmers incomes in the said period (Danik Jagaran dated 25th August, 2018).

1. To find out the ways and means for higher production in less cost of inputs.
2. To advise the ayog for the proper storage of farm produce.
3. To identify the gaps for low production and advice for doubling the farmer's incomes.
4. To find out appropriate suggestions for the development of agricultural technologies, animal husbandry, fisheries, poultry, silk production, agriculture, agro-forestry and milk production, and
5. To develop policies for an overall agricultural development based on different agro-climate.

The Govt. has credited Rs. 456.16/- crores directly in the account of about 23.29 lakh farmers under all the schemes through Direct Benefit Transfer (DBT). It has become the first state in the country regarding the payment to the farmers through DBT. In addition, the state is also giving subsidy to the farmers for the procurement of seeds and fertilizers through DBT scheme.

Constraints and strategies for enhancing farmers incomes: There could be various strategies to achieve growth in farmers incomes within as well as outside the farm sector. Within the farm sector, the increase in incomes come from greater production per unit area as a result of higher yields, as there are yield gaps of between 25% -100% across various crops especially in dry land regions and in some high-value crops even in irrigated areas. India's average yields in most crops are only half that of China's. The increase can also come from higher cropping intensity, lower cost of production, higher prices or a combination thereof. But, yields are not amenable to sudden change as they depend on the type of technology deployed, which cannot be altered in a short span of time. Also, high-yielding varieties need irrigation facilities, which cannot be expanded quickly.

The other strategy to achieving higher volumes of production, with increase in yield, is higher cropping system, which can be taken up only if there is an increase area under irrigation or a greater access to water. This again is not achievable in the short-term despite the fact that there is plenty of focus on the expansion of irrigation through various schemes such as the PMKSY, and the promotion of micro-irrigation. It is also important to consider that higher production from either from better yields or increases in cropping intensity would not only by themselves lead to higher income in the absence of price support mechanism or well-linked up markets for the produce, as witnessed recently in case of pulses.

Reducing the cost of production (of which 11% comprises machinery costs) is most doable, as this requires extension education to the farmers and providing access to low-cost mechanical services to small and marginal farmers, who cannot afford to buy and own costly machines and agricultural equipment. This is happening across states with the opening of custom hiring service centres by cooperatives, producer companies, self-help groups, and private individual operators, as well as large agri-machinery companies, and agricultural start-ups, with and without state support. Similarly, despite the fact that public extension services are more or less dysfunctional due to various reasons, there are many organizations like agricultural set-ups working closely with farmers to provide extension services as part of a package.

The other strategy of increasing farmers incomes through higher and stable prices because of the inability of the states to implement the Minimum Support Prices (MSP) mechanism for two dozen crops. The government has also showed its inability to implement the Swaminathan Committee recommendations of the MSP which is 50% above the cost of production.

Diversification of high-value crops can help to raise incomes, and are also required for social and environmental reasons, as these crops account for a large proportion of the value of output but covers relatively low area. Cereal crops cover 77% of the gross cropped area (GCA), but account for only 41% of the value of output. The fruits and vegetable contribute 26% the value of output; all high-value crops cover 19% of the GCA and account for 41% of the value of output. But there are many policy distortions that undermine diversification, although markets encourage it. The success in this sector depends highly on reforming agricultural markets and improving their performance from the farmers perspective. Further, new channels of procurements, like contract farming, direct purchase, and private wholesale markets in these crops.

The other important step that can help farmers to protect their incomes from production risk is crop insurance. This is also not being implemented properly despite the relevance of crop insurance schemes such as *Pradhan Mantri Fasal Bima Yojna*. This now also covers apart of the market risk as it also provides for compensation for the post harvest losses. However, the scheme covers only 30% of the GCA. There are many issues regarding claims settlement because of the lack of awareness about the schemes, and also the exclusion of the small and marginal farmers.

The strategies for enhancing farmers incomes outside the farm sector include access to off-farm and non-farm employment and occupations like dairy farming or handicrafts besides moving people outside the farming sector altogether. The former measure can help to provide additional and more regular incomes, and the later one can increase income of those left behind in farming. However, the moving people out of the farming sector is hardly unlikely to happen as there are hardly any opportunities for unskilled or semi skilled farm workers outside the sector.

Constraints and strategies for enhancing growth targets: The prospects of doubling farmers incomes by adding up various sources of income growth viz., yield, live stock income, resource use efficiency, cropping intensity, crop diversification, better price realisation, and shifting to non-farm occupations was analyzed by Chand (2017). He reported that it is mainly price realisation that can give the maximum push to income (growing at 13.0%). He also estimated that the required growth rate in different components of sources of income, in order to double the farm income, is as against those achieved in the past. The growth rates required are at least 1% higher than those achieved in most components in the past except in resource use efficiency, cropping intensity, and shift to non-farm occupations. The target for 2022-23 are more than double in case of quality seed supply, electricity supply, and are very high for fertilizers, irrigation, cropping intensity, and high yielding variety coverage. In fact, the area under fruits and vegetables is targeted to reach 26 million hectares from less than 17 million ha in 2013-14, which is a tall order, as is the higher target for cropping intensity, from 40% to 53% in 10 years. Some of the policy reforms suggested towards doubling farmer's incomes like the liberalization of leasing land, as

proposed by the *NITI Aayog* (2016), are likely to have certain adverse impacts on small and marginal farmers unless there are mechanisms to insure that they are not by-passed by various initiatives from the state and the corporate sectors.

Hence, it is evident from the example of Madhya Pradesh, Chhattisgarh and Uttar Pradesh States that different states require varied strategies because of different levels of agricultural development in growth rates and the level of farmers incomes. Therefore, it is concluded from the above discussion that there is an urgent need to focus on high-value crops and rain-fed areas, non-farm occupations, agro-industrialization, strengthening and innovating producer and worker institutions for doubling Indian farmers incomes.

POSTER

GROWTH AND PRODUCTIVITY OF BARELY (*HURDIUMVULGAREL.*) AS AFFECTED BY SOWING METHODS AND NITROGEN FERTILIZER LEVELS**OLA Z. EL-BADRY AND EL-SAYED M. GHEITH***Faculty of Agriculture, Cairo University, Egypt Department of Agronomy, *Corresponding author: Ola Z. El-Badry*

Growth and productivity of barely (*HurdiumvulgareL.*) as affected by two sowing methods (drilling and broadcasting) and three nitrogen levels, i.e. 60, 80 and 100 kg N/fed. (one feddan = 4200m²) were studied at the Agricultural and Experiments Research Station at Giza, Faculty of Agriculture, Cairo University, Egypt during two successive winter seasons 2015/2016 and 2016/2017. The experiments design was split-plot in randomize complete pluck design in four replications. Both of sowing methods and nitrogen levels significantly affected all growth characters, except leaf area index in the second season, as well as grain yield and its related favorable, except spike length and grain weight/spike, in both seasons. Increasing nitrogen levels up to 80 kg N/fed. caused an obvious increase in net assimilation rate, plant height, number of spikes/m², spike length, weight of grains/spike, grain yield, straw yield and harvest index. On the contrary, number of days to 50% heading, leaf area index and crop growth rate produced the maximum values at 100 kg N/fed. Drilling method exceeded broadcasting in all studied characters in both seasons. The interaction had significant effect on leaf area index and number of spikes/m² as well as grain yield which produced the highest values with using drilling method and application of 100 kg N/fed. as well as 80 kg N/fed., respectively in both seasons. It could be concluded that planting barley with drilling method and application of 80 kg N/fed. were the optimum for increasing barley production under the experimental site and the same conditions.

Key words: Barley, sowing method and nitrogen fertilizer.

INTRODUCTION

Barley (*HordiumvulgareL.*) is the forth grain crop both in area and production in the world after maize, wheat and rice. It has the potential to become one of the important cereal crop in Egypt. It grown for green forage or for feeding on its straw as well as its grain also as food by some Arabian trips who live the desert and in dry region for making bread either alone or mixed with wheat. It could also be used for malt industry especially the starch grain of the two–barley cultivars. Barley grown in Egypt in 60480 ha with total production of 102244 t/year (FAO, 2016). To increase barley production in Egypt more efforts should be directed to improve cultural practices, i.e. sowing time, rate and methods, nitrogen fertilization, weed control and using good cultivars. Several investigators found the positive effect of sowing method (Dihiman and Kalra, 1978;; Ghabour, 1995; Gheith et al., 2009) and Hagra, 1985 and nitrogen fertilizer levels (Andreasen et al. 2006; Hayob, 2007; Omar, 2008) on growth, yield and yield components. Therefore, the present study aimed to investigate the growth, yield and its related components of barley under modified microclimate conditions induced by changing in sowing method and nitrogen fertilizer levels.

MATERIALS AND METHODS

A split plot experiment based on randomized complete pluck design with four replications was conducted at the Agricultural and Experiments Research Station at Giza, Faculty of Agriculture, Cairo university, Egypt during the successive winter seasons 2015/2016 and 2016/2017 to study the effect of three nitrogen levels, i.e. 60, 80 and 100 kg N/fed. (one feddan = 4200 m²) and two sowing methods (drilling and broadcasting) on growth, yield and yield components of barley (*HordeumvulgareL.*) cv. Giza 156. Sowing methods were arranged in main plots and nitrogen fertilizer levels were in sub plots. Barley grains (50 kg/fed.) were planted in the third and second week of November in the first and second season, respectively. The grains were handily drilled in rows 20 cm apart in the drilling method and broadcasted in the broadcasting method. Nitrogen fertilizer (urea 46% N) was applied in two equal splits, the first dose was applied before the first irrigation and the second one was added before the second irrigation. All other agronomic operations except those under study were kept normal and uniform for all treatments. Number of days from planting to 50% heading was recorded. Growth characters were determined at 60 and 80 days from planting on five plants basis randomly taken from each sub plot. Samples were carried out to the laboratory and were separated into leaves and stems. Plant materials were dried in a ventilated oven to the constant weight for 48 hours at 70 centigrade to determine the dry matter. Data collection procedure for the following parameters is as under: Leaf area/plant (LA/plant) = leaf length × leaf width × 0.75 × number of green leaves/plant (cm²), Leaf area index (LAI) = Leaf area / plant (cm²) / plant ground area (cm²), Crop growth rate (CGR) = $(W_2 - W_1) / (T_2 - T_1) \times 1 / GA$ (g/m² /day) and Net assimilation rate (NAR) = $(W_2 - W_1) (LnLA_2 - LnLA_1) / (T_2 - T_1) (LA_2 - LA_1)$, mg/dm² /day. Plant height was determined at 80 days from planting. Where: W₁, LA₁ and W₂, LA₂ refer to plant dry weight and leaf area per plant at T₁ and T₂ time of sampling, respectively. Whereas, GA= ground area and $Ln(X) = 2.303 \times \log(X)$. LA/plant was determined using method described by Pearce et al. 1975, while CGR and NAR were calculated according to Watson formula (Radford, 1967). At harvest, number of spike/m², spike length, grains weight/spike, grain yield, straw yield, harvest index were recorded. The recorded data were analyzed statistically by using statistical software package MSTAT-C (Michigan State University, 1990). Least significant Difference (L.S.D.) at 0.05 % probability was employed to test the significant differences among mean values of each treatment (Steet and Torie, 1997).

Results and Dissections

Effect of nitrogen fertilizer levels

Growth characters

Results presented in Table (1) indicate that the difference in all growth characters (time of heading, leaf area index (LAI), crop growth rate (CGR), net assimilation rate (NAR), and plant height) due to changing levels of nitrogen fertilizer were significant in both seasons. It is evident from these results that heading was delayed from 71.6 -75.6 days in the first season and from 72.6 – 74.6 days in the second one by increasing nitrogen levels from 60 to 100 kg N/fed. The increment in heading period may be due to nitrogen addition that favored vegetative growth which in turn delayed time of heading. These results are in harmony with those obtained by Gheith et al. (2013 and 2016). Leaf area index and crop growth rate were increased significantly with increasing nitrogen levels up to 100 kg N/fed. in both seasons. This increase in LAI occurred may be due to the increase in leaf expansion. This finding is in harmony with those recorded by Ali (2012), Alam (2013) and Gheith et al. (2016). Moreover, Either NAR or plant height were increased significantly with increasing nitrogen levels up to 80 kg N/fed and then decreased up to 100 kg N/fed. in both seasons. The highest NAR (11.6 and 12.9) and the tallest plants (64.1 and 74.2) were that fertilized with 80 kg N/fed. in both seasons, respectively. This effect of nitrogen application on plant height may be due to the stimulation effect on internodes elongation. The previous effect of nitrogen on the growth characters may be due to the vital role of nitrogen and its necessity for protoplasm formation, photosynthesis activity, cell division and meristematic activity in plant organs is illustrated. Iqbal et al. (2012) and

Gheith et al. (2016) reported similar results.

Table 1: Effect of nitrogen levels on growth characters in both seasons.

Characters	N levels (kg/ fed.)							
	60	80	100	LSD	60	80	100	LSD
	1 st Season				2 nd Season			
Days to 50% heading	71.6	72.7	75.6	1.1	72.6	73.5	74.5	1.9
LAI (80 days)	4.6	5.0	5.5	0.6	4.4	4.9	5.1	0.2
CGR (60-80 days)	200.1	212.3	225.6	11.5	199.2	210.3	220.4	9.5
NAR (60-80 days)	6.8	11.6	10.8	2.3	7.3	12.9	12.1	1.3
Plant height (80 days)	63.7	64.1	63.8	0.3	70.8	74.2	72.9	1.9

CGR (g/m²/day and NAR (mg/dm²/day.

Grain yield and its related characters

Results presented in Table (2) revealed that there was significant difference in grain yield and its components except spike length due to nitrogen fertilizer levels in both seasons. The application of 80 kg N/fed. caused significant and higher increases regarding number of spikes/m², grain weight /spike, grain yield, straw yield and harvest index. As an average of two seasons, increasing nitrogen levels up to 80 kg N/fed. caused an obvious increase in the previous traits by 30.4, 23.1, 46.4, 50.2 and 7.7% and by 128, 26.7, 8.6, 32.8 and 5.8% over each application of 60 and 100 kg N/fed, respectively. These results were expected that nitrogen is one of the most important components of cytoplasm, nucleic acid and chlorophyll. Therefore, as the level of N increased, rapid multiplication of cells occurs which in turn enhances the amount of metabolites necessary for building plant organs. These results are in harmony with those obtained by Khedr (2004), Woldeyesus et al. (2004), Andreassen et al. (2006), Hayob (2007), Omar (2008) and Gheith et al. (2009).

Table 2: Effect of N levels on grain yield and its components

Characters	N levels (kg/ fed.)

Effect of sowing methods

Growth characters

Results presented in Table (3) showed that sowing methods had significant effect on all studied growth characters in both seasons except LAI in the second season. These results indicated clearly that drilling method produced the highest values compared with broadcasting method. These results are in harmony with those abstained by Dihiman and Kalra (1978) and Gheith et al. (2009).

Table 3: Effect of sowing methods on growth characters in both seasons.

Characters	Sowing methods					
	Drilling	Broad casting	LSD	Drilling	Broad casting	LSD
	1 st season			2 nd season		
Days to 50% heading	74.1	72.2	1.8	75.6	72.3	2.1
LAI (80 days)	5.2	4.2	0.3	4.9	4.8	-
CGR (60-80 days)	220.2	206.1	10.2	326.2	212.1	13.1
NAR (60-80 days)	10.1	8.2	1.6	11.1	8.6	1.9
Plant height (80 days)	63.1	61.1	2.0	66.1	64.1	1.8

CGR (g/m²/day and NAR (mg/dm²/day.

Grain yield and its related characters

As regarding the effect of sowing methods on grain yield and its related components, significant effect were detected in both seasons with respect to number of spikes/m², grain yield, straw yield and harvest index. However, no significant effects on spike length and grain weight/spike were found in both seasons (Table 4). It is rather increasing to note that drilling method exceeded broadcasting method in all studied characters in the two studied seasons. A possible even distribution for this finding is that drilling method most likely ensures characters in such cause would be better than that of the uneven disruption of plants in case of broadcasting method. These results are in harmony with those recorded by Dihiman and Kalra (1975), Hagra (1985) Ghabour (1995) and Gheith et al (2009).

Effect of interaction

The interaction between the two studied factors had significant effect on LAI, number of spikes/m² and grain yield per unit area in both seasons (Table 5). Sowing barley with drilling method and application of 100 kg N/fed. produced the highest LAI (5.4 and 5.1) and number of spikes/m² (408.5 and 410.5), respectively. Whereas, grain yield per unit area recorded the highest values (1.54 and 1.85) under the same method and application of 80 kg M/fed.in both seasons, respectively.

Table 4: Effect of sowing methods on grain yield and its components in both seasons.

Characters	N levels (kg/ fed.)					
	Drilling	Broadcasting	LSD	Drilling	Broadcasting	LSD
	1 st season			2 nd season		
Number of spikes/m ²	380.2	341.4	30.5	382.0	352.3	28.9

ECO-FRIENDLY BEEKEEPING AND CROP PROTECTION IN UTTARAKHAND, INDIA**RUCHIRA TIWARI,***Assistant Professor, Department of Entomology, College of Agriculture, Govind G.B. Pant University of Agriculture and Technology, Pantnagar-263145, Distt. U. S. nagar, Uttarakhand, India*

Honey bees are known for their promising role as a pollinator and forager of plant flora, not only help in increasing the agri-productivity but also provide innumerable valuable products such as honey, beeswax, royal jelly etc. But the efficiency of bees are affected by many agents namely bacterial, viral, fungal diseases, pest, wax moth and predatory wasp. Diseases of bee are the serious problems which in turn cause economic losses to bee keepers and further hamper the expansion of beekeeping and the bee industry worldwide. The bacterial brood disease, European foulbrood (EFB) and diseases caused by ecto and endo parasitic mites, *Varroa destructor* and *Acarapis woodi*, respectively are the severe ones causing severe damage to honey bees (*Apis mellifera*) colonies in Uttarakhand. Whereas among the insect pests, greater wax moth, *Galleria mellonella* causes extensive damage to bee combs by feeding on wax by its larvae and making silken galleries rendering the bee frames unfit for further utilization. The predatory wasp, *Vespa orientalis* (L) attacks the beehives and kill the bees. The beekeepers used antibiotic, terramycin to control EFB and sulphur, formic acid, apistan strips, methyl salicylate, oxalic acid for mite and wax moth control but they found them ineffective. Due to the frequent use of these synthetic chemicals in bee hives the several beekeepers have lost their bee colonies and on the other hand, the development of resistance and contamination of honey due to antibiotic, terramycin has led to a ban on this drug.

Therefore, to combat all these diseases, pest and predators the authoress used cow urine, ajwain seed powder, neem leaf powder, cow dung powder, cow dung ash powder and smoke generated by burning of cow dung and neem leaves at various apiary sites of Uttarakhand during 2008-2017.

The effectiveness and feasibility of using an eco-friendly, non-chemical, animal originated product, cow urine have been explored for the first time in preventing and management of infection of bacterial disease, European Foulbrood (EFB), in the colonies of honey bee, *Apis mellifera* at apiary site pant Nagar, Uttarakhand in 2006 (Mall and Tiwari, 2007). The experiments were also conducted on efficacy of cow urine against EFB disease at various locations of Uttarakhand in the year 2008-2011. It has been observed that the cow urine spray reduced the disease infection to below detectable limit in 10 and 12 days, respectively, as against terramycin treated infected colonies where only 40-45% recovery in EFB infection was observed. Cow urine treated infected combs not only showed rapid and cent- percent recovery in disease infection but also promotion of growth of brood . (Akash and Tiwar,2012). The *in vitro* laboratory experiments were also conducted on the antibacterial activity of the cow urine collected from desi cow in comparison with terramycin on the EFB bacteria of honey bee in the growth of bacteria in different treatments of cow urine was calculated in (mm) and was compared with the growth of bacteria in standard antibiotic, terramycin treated media.(Akash and Ruchira, 2013).

The studies were conducted to manage the ecto-parasitic brood mite, *Varroa destructor* infestation in the bee colonies of *Apis mellifera* (L.) at different locations of Uttarakhand by applying eco-friendly animal origin and plant products. The complied average data of all three apiaries at Dineshpur, Haldwani and Halduchaur revealed that cow urine (desi breed) @ 100%, significantly reduced brood mite infestation (75.60%) with highest mean mite fall (38.00) and sealed worker brood area (SWBA) (1042.00 cm²) followed by cow urine (jersy breed) @ 100% with reduction brood mite infestation, mite fall and Sealed worker brood areas(SWBA) were (75.27%, 37.33 and 991.36 cm²), ajwain powder @ 5g (74.09%, 35.67 and 988.52 cm²) cow urine (Holstein breed) @ 100% (71.57%, 33.00 and 974.34 cm²) and neem leaf powder @ 5g (66.59%, 32.33, 892.32 cm²) in comparison to synthetic chemicals i.e. thymol @ 500mg (58.55%, 29.00 and 464.16 cm²) and formic acid @ 5ml (45.35%, 20.33 and 372.44 cm²) and untreated control.(Tiwari *et al*, 2014). No any adverse effects of these products were observed on bees and the brood and the worker bees worked efficiently and cleaned the infected/ infested brood area and bees in the colonies. It also showed some positive additional effects during the experiments were reducing wasp attack by repelling them away from the beehives and reducing the robbing amongst the bees. The quality analysis of honey samples collected from bee hives treated with these eco-friendly plant and animal origin products were found free from any contamination, with no problem of excess moisture and presence of heavy metals and microbial counts.

The success stories of Indian and German beekeeper, Michael Dryer adopted Cow urine for organic beekeeping s from India and Germany was published

Indian mustard (*Brassica juncea* (L.), is an excellent source of vegetable oil. Being cross pollinated crop attracts large number of pollinators, among them, honeybees being the most prominent. To analyse the foraging activity i.e, foraging rate and time of honeybee, *Apis mellifera* on mustard crop treated with eco-friendly formulations, a novel study was conducted at G.B.P.U.A & T Pantnagar, Uttarakhand during rabi crop season 2015-16. The eco-friendly formulations included animal urine collected from different cow breeds, buffalo and goat @ 20% along with cow urine based plant extracts i.e Neem leaf cow urine extract (NLCUE) and Ajwain seed cow urine extract (ASCUE) @ 1% and 2% were sprayed during peak bloom period of mustard crop. The results showed that there was no adverse effect of tested eco-friendly formulations on foraging behaviour of honeybees, and the maximum foraging rate was observed during the noon hours i.e. 12:00 to 01:00 PM with maximum foraging rate on mustard crop sprayed with desi cow urine @ 20% with (24.0 flowers/bee/min) in comparison to

foraging rate in untreated mustard crop ranged from (15.0-7.0 flowers/bee/min.). Thus, it may be concluded that in this novel research work which was conducted for the first time worldwide and can easily be incorporated to enhance the pollination services of honeybees in mustard crop. (Bisht and Tiwari, 2016)

Similarly, effect of animal and plant origin products were also found effective for growth and development of honey bees. The maximum larval weight of honey bee, *A. mellifera* (128.63mg) and (131.78mg) was observed in desi cow urine treated old bee frames and neem leaf powder treated new bee frames, respectively. The maximum weight of newly emerged adults (112.66 mg) and (118.77mg) was recorded from buffalo urine treated old bee frame and desi cow urine treated new bee frames, respectively. The maximum mean sealed worker brood areas were calculated in old bee frames (304.24cm²) and newly drawn combs (311.63cm²) treated with desi cow urine. (Bisht and Tiwari, 2017)

The commonest method mitigating the problem of major pest of honey bee i.e. wax moth, *Galleria mellonella* (L) is use of harmful chemicals such as Paradichlorobenzene, Naphthalene balls, Celphos (Aluminium phosphide) tablets and Acetic acid. These chemicals not only harm the bees but also create a problem of residue, often leading to problem such as absconding, or colony collapse disorder. Therefore, to overcome the problem of wax moth infestation in empty bee frames under storage conditions, a preliminary and novel approach involving the construction and use of wooden smoke unit to fill cow dung cake smoke generated by burning with neem (*Azadirachta indica*) and jatropha (*Jatropha curcas*) leaves to control the wax moth infestation under airtight and semi airtight storage conditions was conducted at Pantnagar, Uttarakhand during 2014. The study showed promising results as cent- per cent mortality of different stages of wax moth was found in airtight smoke units while under semi airtight conditions the mortalities of adults, larvae and pupae were found 83.33%, 86.66 % and 58.33%, respectively. (Bisht and Tiwari, 2017)

Eco-friendly crop protection :

The eco-friendly formulations were also evaluated against mustard aphid, *Lipaphis erysimi* and its natural enemies and pollinator, honeybees under field conditions whereas the laboratory experiments have been conducted to find out their efficacy against white mold of mustard, *Sclerotinia sclerotiorum* (Tiwari et al 2016). The cow urine at 25% and 100% and cow urine based formulations prepared with plant products i.e. neem and jatropha @2% were found significantly effective against mustard aphid with increase in population of natural enemies, parasitoid, *Diaeretiella rapae* and predator, *Coccinella septempunctata* and pollinator, honey bees. It has been clearly seen that after 3-5 days of spraying of cow urine based formulations, mummified aphids were found on the mustard crop due to attack of parasitoid. The crop yield was also calculated more in cow urine based formulations in comparison to water based formulations and untreated control. Under laboratory conditions, *in vitro* studies on the effect of eco friendly formulations against plant pathogenic fungus *Sclerotinia sclerotium* concluded that the cow urine and cow urine based plant extracts gave cent per cent fungal growth inhibition as observed in fungicide treatment (Carbendazim 50WP) and in comparison to 46.0% to 82.0% fungal growth inhibition in water based plant decoctions which is clearly revealed that eco friendly formulations could be used as an cheap and best alternatives in the management of *Sclerotinia sclerotium*. (Tiwari et al 2016)

A novel and preliminary field study was made on the efficacy of animal urine against gram pod borer, *Helicoverpa armigera* (Hubner) on chickpea (*Cicer arietinum* L.) at experimental farm NEBCRC, GBPUA&T Pantnagar, Uttarakhand during Rabi crop seasons of 2016-17 and 17-18. The pooled data for both the years clearly showed that all the treatments were found significantly superior over control. The data on mean larval population, pod damage and grain yield was obtained for Indoxacarb (14.5 SC) @ 0.9ml/l (3.34larvae/plant, 11.38% and 15.15q/ha) showed that the chemical was performed the best among the treatments followed by Desi cow urine (4.50larvae/plant, 13.00%, 12.92q/ha), Horse urine (4.33 larvae/plant), 13.97%, 12.55q/ha) and Goat urine (5.83larvae/plant, 15.65%, 12.25q/ha) in comparison to untreated control (19.34larvae/plant, 38.70%, 5.51q/ha). On the other hand, the mean population of pupae of parasitoid, *Camptoplex chloridae* was recorded the least (0.78/plant) in Indoxacarb and significantly more per plant (2.42, 2.42 and 2.00) in Desi cow urine, Horse urine and Goat urine, respectively. Thus, the present novel study clearly revealed that animal urine can safely and effectively be incorporated in integrated pest management schedule against *Helicoverpa armigera* on chickpea (Ajaykumara and Tiwari, 2018).

CONCLUSION

These innovative eco-friendly management practices were found as good alternatives to chemicals, to keep the incidence of diseases, pests and predators of honey bees at bay. This expertise technology developed for eco-friendly management of honey bees is a novel approach throughout the world and has been adopted by several beekeepers across India. The beekeepers from Nepal, Germany, Ecuador (South America) and Croatia have also adopted this eco-friendly technology for bee management and getting benefitted. The above mentioned technology has been developed by the financial help obtained from AICRP, Honey bees, Uttarakhand Council for Science and Technology, Dehradun, Uttarakhand and NABARD, Mumbai, Maharashtra.

Thus, it may be concluded that animal origin product, cow urine, botanicals and cow urine based formulations are safe for honey bees, eco-friendly, readily available, almost free of cost to farmers and have long term effect without having any adverse effect on natural enemies and pollinators under field conditions can easily be incorporated as one of the measure

under integrated pest management programme for crop protection. It shall open new avenues for the use of natural bio-resources for their commercial utilization and generation of revenue for farmers of rural areas of Uttarakhand.

THRIPS TABACI: BIOLOGY AND ITS MANAGEMENT**M. SHAFIQ ANSARI¹, MAHER AHMED MORAIET², AND RABIYA BASRI¹**¹Department of Plant Protection, Faculty of Agricultural Sciences, Aligarh Muslim University, Aligarh, India²Division of Entomology, Department of Plant Protection, Agriculture Research Station – Seiyun, Yemen

Onion is an important vegetable crop widely grown and consumed all over the world. It contributes significantly to the Indian economy by exporting 2.41 million tons of onion in 2016-17. India is the second largest producer of onion in the world but lacking behind in productivity (14.21 tons/ha) compared to China. It is cultivated in 1.19 million ha with production of 21.4 million tons in 2017-18. The major onion producing states in India are Maharashtra, Madhya Pradesh, Karnataka, Gujarat, Rajasthan, Bihar, Haryana, Andhra Pradesh, Tamil Nadu and West Bengal that contribute almost 90% of the total onion production. It is cultivated in three seasons; kharif, late kharif and rabi in different states of India.

Onion thrips, *Thrips tabaci* Lindemann (Thysanoptera: Thripidae) is a major insect pests throughout the world. It causes extensive damage to onion due to direct feeding as well as by transmitting economically important Iris yellow spot virus. It also transmits bacteria, *Pantoea ananatis* causing central rot in onion bulb. It damages the stored onion bulbs responsible for blemishing, shriveling and skin separation, and then allowing entry and establishment of black mould (*Aspergillus niger*) and also predispose to other secondary infection when stored at ambient temperature. Primary hosts of *T. tabaci* are onion, cotton, cucumber, tobacco, garlic, leek, cabbage, and black pepper. While, the secondary hosts are potato, melon, tomato, sugarbeet, pigeonpea and cassava. Annual yield loss is estimated to be about 10 to 15% up to 90% in Maharashtra, India and more than 50% in USA.

Adult are elongate, yellow and brown in color with two pairs of fringed (hairy) wings. Mouthparts are beak-like, right mandible is absent or rudimentary and left is functional with seven-segmented antennae. Longevity of adults and life spans are significantly affected by onion cultivars. It reproduces parthenogenetically. However, most species of thrips are reproducing by arrhenotoky. *Thrips tabaci* showed both reproduction modes: arrhenotoky and thelytoky with female biased sex ratios. Males of *T. tabaci* were not recorded on onion culture under laboratory conditions. Thrips hibernates in the winter under the base of plant in soil, debris of crop and other plant habitats.

They become active when temperature warm up in the spring season. Adults migrate to new onion fields with the velocity of wind. Adults also feed on inner leaves in center of onion neck and insert eggs individually into the leaves through their ovipositor.

Onion thrips lay eggs in soft tissues of leaves. Eggs are white-yellow, kidney shaped, microscopic in size. Biology of *T. tabaci* was studied on four cultivars: Onion White (OW), Nasik Red, Nasik Red Plus N-53, and Onion Dr-301 (Krishna). Significant ($P < 0.05$) differences were between thrips population on the cultivars in egg incubation (mean of 3.76 ± 0.10), I instar (mean of 2.01 ± 0.05), pre-pupa (mean of 1.50 ± 0.50), total immature (mean of 11.47 ± 0.17), pre-oviposition (mean of 1.63 ± 0.07), oviposition (mean of 14.66 ± 0.65), post-oviposition (mean of 1.07 ± 0.10), mean total eggs (mean of 61.14 ± 3.01), and fertility life table. However, no significant ($P > 0.05$) differences were found between the cultivars in II instar (mean of 2.41 ± 0.08), pupa (mean of 1.58 ± 0.49), morality of immature stages (mean of $33.71 \pm 3.83\%$), and mean daily eggs (mean of 3.82 ± 0.11). The results provide that onion cultivars are an important factor that affect the biological and life table parameters of *T. tabaci*. Onion White and Nasik Red are more susceptible than Nasik Red Plus N-53 and Onion Dr-301 (Krishna). It is also necessary to consider the cultivars when designing for *T. tabaci* management program.

Monitoring and detection of insect pests and their relative abundance are the foundation of an authentic IPM approach. We suggested that mass trapping of onion thrips is not suitable for the management purpose but can be used only for monitoring on onion crop under field condition. Economic Threshold Level, action threshold (AT) or economic injury level (EIL) may adequately be utilized as decision-making tool in the management of thrips if the density of the thrips reaches or exceeds the threshold level. Infestation of *T. tabaci* does not affect bulb yield under 1 TPD under favorable agro-climatic condition in Aligarh, India. Generally, management of thrips should be mandatory between February and April. The AT varied from 3.52 to 30 TP by different methods for estimation of ETL. However, the estimated AT with 10 TP could be recommended for onion farmers.

The temperature shows positive relationship while, relative humidity significantly negative relationship with the abundance, damage and egg laying of *T. tabaci* in agroeco-system of onion. The infestation of thrips starts from December, establishes in the field in the month of February, and have peaks when temperature $>18^{\circ}\text{C}$ with $< 55\%$ RH (14-22 weeks after transplanting (WAT)) in the month of March and April. Onion cultivars are an important factor that affect the biological and life table parameters of *T. tabaci*. It is also necessary to consider the cultivars when designing for *T. tabaci* management program. Onion White and Nasik Red are more susceptible than Nasik Red Plus N-53 and Onion Dr-301 (Krishna). White Marglobe (7.46-7.80 thrips/plant (TP), 38.92-20.37 t/ha) and Onion Dr-301 (Krishna) (7.68-5.18 TP, 27.44-18.74 t/ha) are suitable for growing in Aligarh, because they are tolerant to thrips with higher yield than other cultivars. Therefore, thrips-tolerant onion varieties could keep down the infestation at low level as well as could minimize the application of insecticides.

Specific potential natural enemies of onion thrips are not found but spiders and coccinellid beetles are the most common predators. More investigations are required to make long-term strategy to exploit the application of natural enemies

in the management of *T. tabaci* on onion crop. Date of transplanting is one of important tactics in the management of *T. tabaci* in the onion field. Onion thrips can be effectively managed by early transplanting (November) and give high yield. Spacing of 30×15 cm (row ×plant) is useful in reducing thrips infestation. The results showed that wider spacing is significantly superior to closer spacing in the management of thrips infestation with high weight of onion particularly with OK, which reduced the thrips population with higher yield. The highest weight of bulbs (2.24-1.84 kg/h 10 onion bulbs) and yield (24.47-29.82 t/ha) were obtained in flatting system. It can be recommended that planting onion in flatting system is the best and suitable method in the management of *T. tabaci* and increasing the production of onion. Carrot can also be utilized as an intercrop in the management of *T. tabaci* on onion, but further need of investigations on their optimal spatial arrangement in an intercropping system to avoid reduction in bulb yield. Application of fertilizers could help onion plant to resist the infestation of OT. Nitrogen dosage at 100 kg/ha (50 kg at basal and rest of 50 kg after one month) is effective for reducing the thrips population. It is recommended that 80 kg P₂O₅/ha (20.93-22.13 t/ha) and 100 kg N/ha (23.05-25.40 t/ha) could give greater production of onion. Lastraw and neemarin (azadirachtin 0.15%) are the economical bio-insecticides that could be use against onion thrips (Moraiet et al. 2015). Dimethoate and imidacloprid gave highest benefit cost ratio (8.22:1 and 6.59:1) on OK, respectively. Therefore, dimethoate 30% and imidacloprid 17.8% can be recommended to manage thrips on onion crops.

Integrated Pest Management:

Integrating practices are adopted for thrips management from transplantation to harvesting on onion crop; I module: - early sowing, flatting system, plant spacing 30×15 cm (row ×plant), nitrogen dosage at 100 kg/ha, 80 kg P₂O₅/ha and three applications of neemarin (azadirachtin 0.15%) at the time of action threshold (10 thrips/plant) was successful in escaping high thrips infestation and producing better yield in comparison to control treatment. Cost/benefit ratio is higher in integrated management than the farmer's ordinary practices.

II module:- late sowing, flatting system, plant spacing 30×15 cm (row ×plant), nitrogen dosage at 100 kg/ha, 80 kg P₂O₅/ha and two application of neemarin (azadirachtin 0.15%) at the time of action threshold (10 thrips/plant), two application of imidacloprid 17.5% SL @1.5ml/L.

III module: flatting system, plant spacing 30×15 cm (row ×plant), wheat as barrier crop, seedling root dip treatment with imidacloprid 17.5% SL @ 0.04% for 12h nitrogen dosage at 100 kg/ha, 80 kg P₂O₅/ha and two application of neemarin (azadirachtin 0.15%) at the time of action threshold (10 thrips/plant).

LEAD PAPER:**GLADIOLUS CULTIVATION FOR FARMERS PROSPERITY****DR. MANOJ NAZIR***Directorate of Agriculture, Talab Tillo Jammu (j and K)*

The word gladiolus was coined from the Latin word gladius meaning sword lily on account of its shape of its foliage. Corn flag is it's another name in Europe G. Illiricus was found wild as weed in corn fields. Water fall Lilly is another name given to it as G.primulinis was found growing near the Victoria Falls in the tropical forests of Africa. It was introduced into cultivation towards end of 16th century. In India cultivation dates back to 19th century, as Firmingers manual of gardening in India published in 1863 mentions that Charles Grey of coonoor grew some gladiolus from corms and seeds in his garden.

Gladiolus cultivation under northern Indian plains, coastal areas of TamilNadu and Pondicherry has a potential to change the economic scenario of farmers of these areas. For generating both money as well as employment in rural areas gladiolus is such a crop suitable for establishing floriculture industry by progressive farmers and entrepreneurs and undoubtedly the best bulbous flower in India. Its magnificent spikes in dazzling colours remain fresh for 10 to 22 days. Its cultivation in Jammu region has become an important sector as consumption of flowers is rising associated with economic development. Jammu division of J and K has a wide range of climates and micro climates different production system, socio economic diversity and consumer requirements. Mostly farmers belong to small and marginal category. Diversification to horticulture crops is now the major option to improve livelihood security of small farmers and improved employment opportunities. Jammu division of (J and K) and coastal plains of India is going to play a vital role in floriculture trade which will turn the economy of these states. Floriculture scenario in Jammu province of (J and K) has changed very rapidly since 2000. In 1998 – 1999, area under gladiolus cultivation in Jammu province was 0.5 hec and its reached to 2.0 hec. In 2002 and 5.0 hec in 2004 and 10.0 hec in 2007. Now every year 25 – 50 farmers take up its cultivation in Jammu region of J and K. In 1999 40,000 spikes of gladiolus were produced, from 1999 – 2002. 1, 00,000 spikes were produced. From 2002-2004. 1, 20,000 spikes were produced and from 2005-2007. 3, 00,000 spikes were produced from the plains of Jammu region (from October to April). Despite all this Jammu import 85% of gladiolus spikes and other cut flowers from rest of the country. Floriculture sector is experiencing a rapid change the world over the globalization and its effect on income generation. Consumption of gladiolus spikes in northern plains of India and coastal plains is rising day by day and this trend will continue to increase because of its demand in the market and improvement in purchasing power. A gladiolus spike has a potential to change economic scenario of poor farmers.

Recent trends:

Consumers are becoming more aware of what to buy. They are becoming professional buyers. They tend to ask for higher choices in product quality levels depending on purpose of purchase, as well for higher levels of service and a wider and deeper assortment. Now the trend has shifted from seasonal to year round production of flowers and the soil of Jammu has potential to make spikes of gladiolus available when they are most wanted (like mothers day, Valentines Day) besides marriages, birthdays and other occasions. FAO-sponsored project on green house technology for small scale farmers should be implemented in Jammu, western U.P, and Coastal plains of Tamil Nadu which will give a confidence to farmers for green house production of flowers. Government of Jammu and Kashmir, U.P and Tamil Nadu should be instrumental in setting up of floricultural units both for export and domestic markets. Cold storage facilities for flowers for export should be set up.

Why Gladiolus has become farmer's first choice

Farmers feel secure by cultivating gladiolus as the spikes fetch then a good return in comparison to other crops and can be also intercropped with vegetables like Knolkhol, radish and floricultural crop like French marigold and gerbera.

CROP	AREA (Hect.)	TOTAL INCOME (Rs.)
Wheat	1.6	72,000.00
Paddy	2.0	40,000.00
Radish	0.2	12,000.00
Cabbage	0.3	06,000.00
Spinach	0.1	500.00
Gladiolus	0.1	28,000.00
Knol kohl	0.5	2,000.00

Year	Area under Cultivation (Hects.)	Total No. of Spikes produced	Total No. of Farmers engaged	Profit (Rs.)
1998 – 99	0.2	12000	05	18000
1999 – 2000	0.3	18000	07	27000
2000 – 01	0.5	30,000	10	60000
2001 – 02	0.5	30,000	12	65000
2002 – 03	1.0	1,20000	14	245000
2003 – 04	2.0	240000	20	480000
2004 – 05	3.0	300000	25	860000
2005 – 06	3.5	4,20000	35	12,60000
2006 – 07	4.0	4,80000	40	14,44,000
2007 – 08	4.5	5,40000	46	16,00000
2008 – 09	6.0	6,60000	60	20,00000

Status of Gladiolus in Jammu (J&K)

Gladiolus cultivation has not only a potential to change economic status of a poor farmer but also a good mode of diversification

Floriculture has become one of the important high value agricultural industries, in many countries of the world. Due to globalization and its effect on income enhancement in different regions of the world, a growing percapita consumption of floricultural products is witnessed in most of the countries

The traditional flowers like Jasmine, marigold, chrysanthemum, and tuberose are the mainstay in India. With increase in importance of protected cultivation and green house technology combined with liberalized trade policies and many concessions given to entrepreneurs, many companies have ventured into growing flowers for exports

Major cut flowers grown in India are Rose, orchids, gladiolus, carnation, anthurium and gerbera. India is especially well placed to meet international demand for cut flowers which peak during winter months. Indian floriculture has recently witnessed commendable changes which have transformed it from hobbyist activity to a commercial enterprise. The value of import and export is increasing every year.

Objects of the mission

1. To make this crop popular in India (666 distt.)
2. To Identify promising and stable genotypes for All locations of India
3. To help and guide the farmers about its commercial importance and how it can improve the economic status

What is a Colour Revolution?

It is revolution through colorful spikes of gladiolus that will enhance the economic status of our majority of poor farmers

The Netherlands's also a big importer but re exports most of its imports. Indian cutflowers like gladiolus, roses, gerbera, carnation are liked by these countries and could import these flowers during winter months when these flowers could not be cultivated there during winter months and can also promote close diplomatic relations with these countries.

Europe and other countries are increasingly looking towards India for cut flowers. The climatic conditions in most of these countries don't favour year round cultivation of cut flowers.

Flowers like Roses, gladioli, carnation and orchids are enthusiastically received in Japan, Germany the Netherlands, U.K and Hongkong. The Indian floriculture industry occupies 1, 06,000 hectares. And produced 5, 35,000 million tones of loose flower and 2565 million numbers of cut flowers resulting in an export of Rs. 1150 million and out of the total area approximately 58, 000 hectares. Is under annual flowers.

Why gladiolus crop selected for this mission

For generating both money as well as employment in rural areas gladiolus is such a crop suitable for establishing floriculture industry by progressive farmers and entrepreneurs and undoubtedly the best bulbous flower in India. Its magnificent spikes in dazzling Colour remain fresh for 10 to 22 days. Gladiolus cultivation has a potential to change the economic scenario of farmers of this country

After extensive touring from length to breadth of India we could gather that mostly our farmers belong to small and marginal categories are struggling hard. They do not earn much from their traditional crops. And diversification to horticultural Crops is now the major option to improve livelihood security of small farmers increase employment opportunities through earning foreign exchange. We want to provide a security cover to our farmers and gladiolus as a cut flower has that potential

I select a few farmers with the help of extension officers of department of Agriculture or scientists of the Universities of that area brief them about its cultivation; lay down research trials directly at farmers fields. After successful trials we publish technical brouchers in regional languages and in English. And give live demonstration on spot.

A blooming spike of Pondicherry

The spike of gladiolus from plains of India is more colorful, attractive, more number of florets per spike in comparison to temperate regions of India. The results of coastal areas of Tamil Nadu and Pondicherry were beyond our expectations the spike of gladiolus from Indian soil is more fascinating and has export potential. The demand of its cut flowers is rising day by day and North America is the biggest market

COST BENEFIT RATIO

Cost of one corm ranges between Rs.2-3. If grown scientifically and only stable and promising varieties for that area a farmer can get 2-3 spikes per corm. Cost of cultivation per corm is 25 paisa. Market value of one spike is 3-4 rupees. Total min. amount earned is Rs. 6-9 per corm. Net profit from spikes is Rs. 6-9 minus 2.25-3 .25 = 3.75- 5.75. It means from one acre of land a farmer can earn a net profit of rupees 1, 20,000 – 1, 84,000. From 32000 corms planted in one acre of land.

Other surprise is that after 45 days of spike cut a farmer gets now 2-3 corms back from one planted corm which can be used for next sowing after dormancy break for three months. More so a farmer gets 5- 20 cormlets which grows into well developed corm in three – four months. That is why I have been telling that a single corm of gladiolus has a potential to change economy of our farmers. That is why I selected gladiolus crop for bringing Colour revolution in India. A colorful farmer means a colorful India.

Till April 2017, we had laid 10,000 trials and farmers cooperated with us. They were very enthusiastic. In Jammu, 0.05 ha. of land was under its cultivation before this mission .Today40 ha. of land is under its cultivation.

The farmers of coastal Tamil Nadu and Pondicherry were unaware about its cultivation despite being one of the “Flower growing belts” of India.

They grow gladiolus for the first time in their fields. More and more farmers are coming forward for its cultivation after seeing its rising demand in the national and international markets. This season twenty farmers in Chidambaram (Tamil Nadu) went for its cultivation

Yes a positive change was visible among the farming community. A milk seller turn to progressive gladiolus grower in Jammu. From 0.1 hecets of gladiolus crop he earned a net profit of Rs. 14,000 per crop more than what he earns from 0.2ha of. Radish. On seeing economic boost and visible change in his economy he converted his whole land into gladiolus crop. On seeing the achievements of this farmer other farmers of this vicinity had adopted the same practices. Nowadays, each and every farmer in Jammu region is going for this cultivation. This year up to April 09 four lakh spikes of gladiolus were produced from Jammu plains and still 80 % of spikes we have to import from other states.

Other progressive farmer at R.S Pura (Jammu) a teacher by profession not only sells spikes of gladiolus but now he develops corms from cormlets and exports them to those growers where from he used to import corms for cultivation. A farmer sh. Srinivas Perumal of village C Mutlur of Chidambaram on growing gladiolus for the first time in 2008 noticed a visible change in his economy and decided to go for it extensive cultivation. On noticing, SBI. C.Mutlur is ready to give crop loans. For the commercial cultivation of gladiolus.

We have made a documentary on scientific cultivation of gladiolus entitled “Exploring Gladiolus for Colour revolution in India” presently it is dubbed in Hindi and English now I will dub it in Telugu and Tamil for the farmers of these regions totally free of cost that will enable them to know more about its cultivation. we have also published technical brouchers about scientific cultivation of gladiolus in Hindi, Urdu, Dogri, Kashmiri, Tamil languages till date besides English.

Cost of one corm ranges between Rs.2-3. If grown scientifically and only stable and promising varieties for that area a farmer can get 2-3 spikes per corm. Cost of cultivation per corm is 25 paisa. Market value of one spike is 3-4 rupees. Total min. amount earned is Rs. 6-9 per corm. Net profit from spikes is Rs. 6-9 minus 2.25-3 .25 = 3.75- 5.75. BIOPESTICIDE: AN ECOFRIENDLY APPROACH FOR SUSTAINABLE FUTURE**RASHMI NIGAM, JOGINDER SINGH, RAM JILAL AND WAJID HASAN***Department of Plant Pathology, Janta Vedic College, Baraut, Baghpat (U.P.)**Department of Plant Pathology, Janta Vedic College, Baraut, Baghpat (U.P.)**Division of Crop Protection, ICAR- Indian Institute of Sugarcane Research, Lucknow 226002**¹Krishi Vigyan Kendra, Jahanabad-804432, Bihar, India (Bihar Agricultural University, sabour Bhagalpur)*

Agriculture is central to human survival it provides food and fuel and other ecosystem services, is an important source of livelihood, and plays a crucial role in economic development, it also plays a role in improving economy of the country. Emphasis of present day agriculture is to produce more with lesser land, water and man power. The Green Revolution technology adoption has increased wide varieties of agricultural crop yield per hectare which increased food supply in developing countries. Inputs like fertilizers, pesticides helped a lot in this regard. But in spite of this fact, food insecurity and poverty still prevails prominently in our country. Use of chemical pesticides and fertilizers have caused negative impact on environment by affecting soil fertility, water hardness, development of insect resistance, genetic variation in plants, increase in toxic residue through food chain and animal feed thus increasing health problems and many more which makes bio pesticides to come into picture. The present study deals with different type of biopesticide used in agriculture for the sustainable development.

Keywords: Biopesticide, Ecofriendly, Biofungicide, Sustainable.

INTRODUCTION

Agriculture plays a vital role in a developing country like India. Apart from fulfilling the food requirement of the growing Indian population, it also plays a role in improving economy of the country. The Green Revolution technology has increased wide varieties of agricultural crop yield per hectare which increased 12-13% food supply in developing countries. Inputs like fertilizers, pesticides helped a lot in this regard. But in spite of this fact, food insecurity and poverty still prevails prominently in our country. The indiscriminate use of chemical pesticides and fertilizer in modern agriculture resulted in the development of several problems such as pesticide resistance insects, resurgence of target and non-target pests, destruction of beneficial organisms like honey bees, pollinators, parasitoids and predators and pesticide residue in food, feed and fodder (Al-Zaidi *et al.*, 2011). Sustainable food security requires not only that all people at all times have access to sufficient and nutritious food, but also that this food be produced with minimal environmental impact. Sustainable agricultural development, instead, requires that agriculture meet the needs of the present without compromising the ability of future generations to meet their own needs.

Hence, the today's need is to produce maximum from the decreasing availability of natural resources without adversely affecting the environment. Therefore, alternative, environmentally safe methods are needed for pest management. The present study deals with different type of biopesticide used in agriculture

Bio-pesticides are ecofriendly pesticides which are obtained from naturally occurring substances (biochemicals), microbes and plants. They are also biochemical pesticides that are naturally occurring substances that control pests by nontoxic mechanisms. Biopesticides are living organisms (natural enemies) or their products (phytochemicals, microbial products) or by products (semiochemicals) which can be used for the management of pests that are injurious to plants. They pose less threat to the environment and to human health. Bio-pesticides for Insect-pest and Disease Management, Biological Pest Control and Biological Weed Control are some of the methods for minimizing the adverse effect of pesticides. Bio-pesticides are ecofriendly pesticides which are obtained from naturally occurring substances (biochemicals), microbes and plants (Dutta, 2015). They are also biochemical pesticides that are naturally occurring substances that control pests by nontoxic mechanisms. Biopesticides are living organisms (natural enemies) or their products (phytochemicals, microbial products) or by products (semiochemicals) which can be used for the management of pests that are injurious to plants. The most commonly used biopesticides are living organisms, which are pathogenic for the pest of interest. These include biofungicides (*Trichoderma*), bioherbicides (*Phytophthora*) and bioinsecticides (*Bacillus thuringiensis*). There are few plant products also which can now be used as a major biopesticide source (Salma *et al.*, 2011). Biopesticides are an important ingredient of Integrated Pest Management (IPM) packages due to their capability in maintaining the natural diversity without the use of any artificial or synthetic residues. The origin of Biopesticides can be microbial (bacteria, fungi or virus), herbal (plant extracts) or genetically modified plants (GM). *Beauveriaspp.*, *Trichodermaspp.*, and *Bacillus spp.*, are some of the microbial biopesticides. Biopesticides may be broadly categorized into three major groups: 1) Biochemical biopesticides 2) Microbial pesticides and 3) Plant-Incorporated Protectants (PIPs).

Biochemical pesticides are herbal-based substances that are naturally produced by a plant or an organism. They are non-toxic and biodegradable. Plant biochemicals are collectively called botanicals and the most important botanical is pyrethrum, followed by neem, rotenone and essential oils, typical used as insecticides (e.g. pyrethrum, rotenone, rape seed oil, quassia extract, neem oil, nicotine), repellents (e.g. citronella), fungicides (e.g. laminarine, fennel oil, lecithine), herbicides (e.g. pine oil), sprouting inhibitors (e.g. caraway seed oil) (Isman, 2006). They help the plant in counter-attacking its pests or producing chemicals that would prevent pest attack on the plant.

Microbial pesticides originate from micro-organisms such as bacteria, fungi or other protozoan groups. The widely used microbial pesticides are *Trichoderma viride*, *Bacillus thuringiensis*, *Bacillus sphaericus*, *Pseudomonas fluorescence* (Bacteria), *Beauveria bassiana* (Fungi), Baculo virus and Nucleopolyhedrosis Virus. These are mostly target-specific organisms that are aimed at killing one or a group of pests. Microbial pesticides consist of a microorganism (e.g., a bacterium, fungus, virus or protozoan) as the active ingredient.

Plant-Incorporated-Protectants (PIPs) These are genetically modified materials produced by modifying a protein and introduced into the plant so that it produces its own pesticide. For example, the gene for Btpesticidal protein, was introduced into the genetic material of cotton plant and plant manufactures the substance that destroys the pest.

Applications of Biopesticide

Biopesticides are usually applied in a manner similar to chemical pesticides, but achieve pest management in an [environmentally friendly](#) way. With all pest management products, but especially microbial agents, effective control requires appropriate [formulation](#) (Burges, 1998) and [application](#) (Matthews *et al.*, 2014, Lacey and Kaya, 2007). Biopesticides for use against crop diseases have already established themselves on a variety of crops

Advantages of Biopesticide

Biopesticides are usually inherently less toxic than conventional pesticides. No harmful residues detected.

Biopesticides generally affect only the target pest and closely related organisms, in contrast to broad spectrum, conventional pesticides that may affect organisms as different as birds, insects and mammals.

Biopesticides often are effective in very small quantities and often decompose quickly, resulting in lower exposures and largely avoiding the pollution problems caused by conventional pesticides. It can be cheaper than chemical pesticides when locally produced.

When used as a component of Integrated Pest Management (IPM) programs, biopesticides can greatly reduce the use of conventional pesticides, while crop yields remain high. Biopesticides can be more effective than chemical pesticides in the long-term

CONCLUSION

To develop eco-friendly pest control technologies are the need of day and challenging tasks for developing countries to improve agricultural productivity in a sustainable manner. Biopesticides are considered as one of the eco-safe alternatives due to their biodegradation in nature, multiple mode of action on target pests and may not leave toxic residues, are used globally for controlling insect pests and diseases.

MANAGEMENT OF DIAMOND BACK MOTH, *PLUTELLA XYLOSTELLA* L., IN BRASSICAS**WAJID HASAN¹, NIDA ASIF¹, RASHMI NIGAM AND JOGINDER SINGH**¹Krishi Vigyan Kendra, Jahanabad-804432, Bihar, India (Bihar Agricultural University, sabour Bhagalpur)

Agricultural intensification and greater production of Brassica vegetable and oilseed crops over the past two decades have increased the pest status of the diamondback moth (DBM), *Plutellaxylostella* L. (Lepidoptera: Plutellidae), and it is now estimated to cost the world economy US\$4-5 billion annually. Proven technologies for the sustainable management of DBM currently exist, but overcoming the barriers to their sustained adoption remains an enormous challenge (Furlong et al, 2013). Diamondback moth, *P.xylostella*) is a major pest of cruciferous plants around the world (Talekar & Shelton 1993). It is known to be resistant to main groups of insecticides (Perez et al. 1995), ranking among the twenty most resistant pest species reported up to now (Mota-Sanchez et al. 2002; Mohan & Gujar 2003; Shelton 2004). The *P.xylostella* has a cosmopolitan distribution and its occur where brassicas are grown (Talekar and Shelton, 1993). It is highly migratory with seasonal movement (Talekar and Shelton, 1993). It has 20 generation per year in tropics and due to its genetic elasticity, it leads to development of resistance insecticides (KahutiaGathu et al 2009, Shelton, 2004). The diamond-back moth, *P.xylostella*, appeared in the beginning of September and population steadily reached its peak by the end of November followed by a declined phase from the last week of December to the last week of January. The pest population abruptly increased from February and peaked in April. Overall study revealed temperature as key abiotic factor in regulating the field population of *P. xylostella*. Hot conditions favoured its multiplication while cold ones in November-February limited it (Shukla and Kumar, 2004). Diamondback moth, *Plutellaxylostella* (L.), became the major pest of Brassica vegetable production in Guangdong, a province in southeastern China, in the late 1980s and has continued to challenge growers, particularly during the spring and autumn. Local production breaks, and strict post harvest hygiene are associated with lower pest pressure on large-scale production units. As more and more insecticides become ineffective the need to implement an insecticide resistance management strategy, as well as basic integrated pest management practices, will become more pressing. The potential use and development of a better forecasting system for diamondback moth that will assist these developments is outlined (Zhenyu et al 2012). Since 1993, the annual worldwide cost of diamondback moth, *P.xylostella* (L.) control has been routinely quoted to be US\$1 billion. This estimate requires updating and incorporation of yield losses to reflect current total costs of the pest to the world economy.. The "length of the string" is somewhere between US\$1.3 billion and US\$2.3 billion based on management costs. However, if residual pest damage is included then the cost estimates will be even higher; a conservative estimate of 5% diamondback moth-induced yield loss to all crops adds another US\$2.7 billion to the total costs associated with the pest. A conservative estimate of total costs associated with diamondback moth management is thus US\$4 billion-US\$5 billion (Zalucki et al, 2012).

The preoviposition (1-5 days) and oviposition period (6-14 days) decreased with increase in temperature. Lifetime fecundity was highest at 20 degrees C, followed by 15 degrees C. An increase in egg hatching was also observed with the increase of temperature up to 25 degrees C. Growth period of individual life stages, and hence, the total life cycle duration, decreased with the increase of temperature. Growth index was higher at 25 degrees C than at 30 degrees C. Similarly, larval survival and adult emergence were highest at 25 degrees C. Larval size in instars were maximum at 25 degrees C and minimum at 30 degrees C (Gupta et al, 2013). The mean incubation period ranged from 3.25 to 4.24 days at 24.73 to 28.07 degrees C. The larval and pupal period lasted for 9.83 to 14.25 and 5.72 to 5.99 days, respectively at 24.74 to 31.55 degrees C and 39.50 to 58.76 per cent relative humidity. With the rise in temperature, adult emergence decreased from 100 to 75 per cent. Maximum adult longevity (5.62 days) was observed at temperature range of 26.47 to 29.34 degrees C. The temperature and humidity also affected the fecundity. The maximum number of eggs (168.50) were laid at 24.74 to 27.50 degrees C and 51.93 to 58.76 per cent humidity. The mean time taken to complete the life cycle was 27.43 days with a range of 19 to 40 days (Kaur et al, 2012).. Significant fewer males were captured in pheromone-treated and conventional-practice fields than in the blank control field, but the difference was not significant between the pheromone-treated and conventional-practice fields. In addition, fewer eggs and larvae were observed in pheromone-treated fields. Our results suggest mating disruption coupled with minimal insecticidal supplements is a promising solution for resistance management and control of diamondback moth infestation (Qu et al, 2012). *P.xylostella* is one of the main pests that affect vegetable commodity output. Current treatment by chemical pesticide spray has been considered the effective control of *P. xylostella*. This treatment has also developed the insecticide resistance, increased pesticide residue risks and threatened pollution-free vegetable production. In the present study, the effects of abio-chemical conditions such as temperature, soil moisture, water-logging and soil cover on *P. xylostella* pupae eclosion were investigated. The rate of pupa emergence exceeded 73% at 26-30 degrees C, which declined to 46.67% at 34 degrees C. When treated at 4 degrees C and then grown at room temperature, the rate of pupae emergence dropped significantly. The longer the 4 degrees C pretreatment, the lower was the rate of pupae emergence. However, the emergency rate recovered to normal levels after long time of growth at room temperature. When soil moisture was 10% and 20%, the emergence rate was respectively 12.5% and 6.2% of that under normal moisture condition. No pupa emergence was observed within 6 d at soil moisture of 30%. When treated with water-logging for 12 h and 24 h and then returned to surface soil, the rate of emergence of *P. xylostella* pupae dropped respectively by 25.0% and 50.0% and emergency was delayed too.

No pupa emergence was observed under extended treatment time of 36 h. Soil covering also had noticeable effects on *P. xylostella* pupa emergence. The emergence of pupae was delayed by 2 d when covered at 1 cm depth soil. Pupa did not successfully emerge when soil cover was 1.5 cm deep. The above results suggested that timely irrigation, paddy/dryland rotation and soil plowing were critical control factors of *P. xylostella* pupae in vegetable fields (Zhou et al, 2012). The effects of host-plant resistance on the olfactory response and parasitism success by *Cotesiavestalis*, a parasitoid of diamondback moth (*P. xylostella*) larvae were examined. Here, it was demonstrated that host-plant resistance can strongly influence foraging behavior and parasitism success of the parasitoid. In olfactometer experiments, *C. vestalis* did not differentiate between crucifer plant types with similar levels of susceptibility or resistance to *P. xylostella* but showed a strong preference for susceptible compared with partially-resistant host plants. The influence of previous oviposition activity varied with the host-plant type experienced by the parasitoid. In cage experiments, *C. vestalis* preferred to parasitize *P. xylostella* larvae on a susceptible plant compared with larvae on a partially resistant host plant when exposed to hosts for 24 h. However, this preference appeared to be transitory, and was not found after 96 h exposure. Combining partial host-plant resistance with biological control by *C. vestalis* for the control of *P. xylostella* may in some circumstances be antagonistic and negatively affect parasitism success (Karimzadeh et al 2013).

The susceptibility of field populations of *P. xylostella*, increased their resistance to lambda-cyhalothrin, but there is little or no resistance to spinosad and indoxacarb and reduced resistance to methamidophos. This mitigation of resistance in DBM is attributed to, in particular, a decade-long regional adherence by the vegetable industry of rotating spinosad with indoxacarb in a two-windows-per-year rotation strategy. The original insecticide resistance management rotation strategy had to be updated to incorporate chlorantraniliprole registered as a foliar spray, and recently a mixture of chlorantraniliprole and thiamethoxam as a seedling drench. Seedling drenches have been removed from the two-window strategy used for foliar sprays, with drenches now aligned with periods targeting the highest pest pressure, allowing mode of action (MoA)-free periods and rotation of different MoA insecticides to mitigate any resistance build-up in DBM (Walker, 2012). The feeding potential of *P. xylostella* was significantly higher on cauliflower (6.35 cm²) followed by cabbage (6.22 cm²), and then broccoli (4.22 cm²) and mustard (2.37 cm²) (Tufail et al, 2012). Fipronil 80 WG was tested in the field at three dose levels (50, 62.5 and 75 g a.i./ha) against Diamond back moth in Cabbage in rabi season of two consecutive years, 2009 and 2010 at University Experimental Farm, BCKV, Kalyani, West Bengal. Two standard check i.e., Cartap Hydrochloride 50 SP @ 250 g a.i./ha, Spinosad 2.5 SC @ 15 g a.i./ha along with a untreated check were also taken for comparison. The highest yield were recorded in Fipronil 80 WG treated plots @ 75 g a.i./ha followed by 62.5 g a.i./ha of the same product. Fipronil 80 WG was also found to be very soft to major predatory groups (Alam et al 2014). Eleven pesticides were effective (emamectin benzoate, cartap, tolfenpyrad, fipronil, pyridalyl, chlorfluazuron, teflubenzuron, BT-kurstaki, BT-aizawai, chlorantraniliprole and flubendiamide: 85.7 to 100% lethal), whereas three (permethrin, acetamiprid and clothianidin) were ineffective (6.7 to 36.7%). Nine pesticides were harmless against the native parasitoid *Cotesiavestalis* (acetamiprid, emamectin benzoate, pyridalyl, chlorfluazuron, teflubenzuron, BT-kurstaki, BT-aizawai, chlorantraniliprole and flubendiamide: 0 to 20%), whereas five were harmful (permethrin, clothianidin, cartap, tolfenpyrad, and fipronil: 53.3 to 100%) (Kikuchi et al 2013). Using high doses of insecticides is very dangerous for the environments and for humans. Decreased concentrations are necessary. Insecticides have lethal and sublethal effects. Understanding of some fundamental aspects of DBM biology and ecology, particularly host plant relationships, tritrophic interactions, and migration, has improved considerably but knowledge of other aspects, e.g., its global distribution and relative abundance, remains surprisingly limited. Biological control still focuses almost exclusively on a few species of hymenopteran parasitoids. Although these can be remarkably effective, insecticides continue to form the basis of management; their inappropriate use disrupts parasitoids and has resulted in field resistance to all available products. Improved ecological understanding and the availability of a series of highly effective selective insecticides throughout the 1990s provided the basis for sustainable and economically viable integrated pest management (IPM) approaches. However, repeated reversion to scheduled insecticide applications has resulted in resistance to these and more recently introduced compounds and the breakdown of IPM programs.

DEVELOPMENT OF ORGANO-CHEMICAL FERTILIZER WITH HORMONE MIXED FORMULA FOR SOIL IMPROVEMENT AND GROWTH OF MAIZE (ZEA MAYS L.)**AGBESI KWADZO KETEKU*, PUMISAK INTANON AND SUWAT TERAPONGTANAKORN***Department of Agronomy/Fertilizer Technology, Faculty of Agriculture, Naresuan University, Muang Phitsanulok, Thailand*

In this study, a new fertilizer was developed for soil improvement and growth of maize. Six treatments; T1 control (no fertilizer), T2 NPK (15-15-15), T3 chemical and granular organic fertilizer with hormone mixed formula 1 (HO-1), T4 formula 2 (HO-2), T5 formula 3 (HO-3) and T6 granular organic fertilizer (GOF) were replicated thrice in RCBD, in a plot size of 6 m x 5 m at Phitsanulok, Thailand, 2017. The maize cultivar (*Pacific 999 Super*) was sown at a row and inter-row spacing of 75 cm x 25 cm. Fertilizer rate of 50 kg rai⁻¹ (rai = 0.16 ha) was used. Among the fertilizers treatments, T5 (HO-3) had the highest best balanced plant nutrients N (10.9 %), P (9.3 %), K (9.2 %), Ca (7.97 mg kg⁻¹), Mg (1.6 mg kg⁻¹), S (0.05 mg kg⁻¹), micronutrient, OM (1.25 %), CEC (21.9 cmol kg⁻¹), EC (1.9 dS m⁻¹) and pH (7.6). The initial soil analysis showed a lower rate of soil properties, however after the trial a significant ($p < 0.05$) improvement were observed, the highest residual NPK (0.875 %, 0.0275 % and 0.0267 %) and other properties were evident in T5 (HO-3). Plant height, leaves number, stem diameter, dry matter, leaf area and leaf chlorophyll content (275.5 cm, 19.4, 33.4 mm, 286.56 g, 155.09 dm² and 57.98) respectively were highest in HO-3 treatment. A significant 54.6 % increment in total dry matter was obtained with HO-3 over control. Plant growth indices; RGR (0.142 g g⁻¹ day⁻¹), LAI (5.92) and dry matter efficiency (36.4 %) were best in HO-3. The percentage increment of leaf area index of HO-3 was 57.1 % compare to the control. HO-3 was the best fertilizer for soil improvement and enhancement of maize growth.

Keywords: Growth: HO: maize: NPK: soil improvement**COMPARATIVE ANALYSIS OF FERTILIZER MANAGEMENT SYSTEMS ON YIELD, YIELD COMPONENTS AND PRODUCTION ECONOMICS OF "PACIFIC 999 SUPER" MAIZE CULTIVAR IN THAILAND.****AGBESI KWADZO KETEKU*, PUMISAK INTANON SUWAT TERAPONGTANAKORN AND RUANKWAN INTANON***Department of Agronomy/Fertilizer Technology, Faculty of Agriculture, Naresuan University, Muang Phitsanulok, Thailand*

This trial was conducted to offer on-research evidence to the universal dispute on the economic viability and productivity of divergent fertility management strategy (chemical, organic and integrated approach), Six treatments: T1 control (no fertilizer), T2 NPK (15-15-15), T3 chemical and granular organic fertilizer with hormone mixed formula 1 (HO-1), T4 formula 2 (HO-2), T5 formula 3 (HO-3), T6 granular organic fertilizer (GOF), replicated thrice in RCBD, in a plot size of 6m x 5m at Phitsanulok, Thailand. A fertilizer dose of 50 kg rai⁻¹ (rai = 0.16ha) was used. The maize cultivar (*Pacific 999 Super*) was sown at a row spacing of 75 cm and intra-row spacing of 25 cm. The experimental results revealed that T5 (HO-3) treatment produced the highest yield components and a significant ($p < 0.05$) yield of (1,524.27 kg rai⁻¹), representing an increase of (54 %) over the control. Also, HO-2 and NPK treatments recorded equal effects on maize yield (1,287.20 and 1,262.67 kg rai⁻¹) respectively. From the economic studies, the production cost of HO-3 was the highest (6,103.98 baht rai⁻¹), seemingly, it gave the best revenue of (12,663.49 baht rai⁻¹) and profit (6,559.51 baht rai⁻¹). A significant 17.4 % rise in profit was realized with HO-3 application over NPK treatment. Moreover, the Benefit: Cost ratio of HO-3 fertilizer was the best (2.33) and ideally suitable for maize farmers to maximize returns in Phitsanulok.

Keywords: Fertilizer: hormone: maize: profit: yield improvement**ISOLATION OF METHYL EUGENOL FROM OCIMUM BASILICUM LEAVES AND INFLORESCENCE AND ASSESSMENT OF THE PLANT POTENTIALITY AS FRUIT FLIES ATTRACTANT****AMANI M. K.ABBAS¹, FAIZA M. A. MAGID² & SELMA M. O.ABDULLAH³***^{1&3}Department of Zoology, faculty of science and Technology, University of Shendi, Sudan. ²Department of Pests and Plant Health, College of Agriculture, University of Bahri, Khartoum North, Sudan*

Ocimum basilicum L. (basil), which is annual plant belong to the plant family Lamiaceae. Methyl Eugenol was found as one of the basil oil component. This study was carried out at Shendi area to assess the amount of Methyl Eugenol extracted from the plant and the potentiality of raw plant as fruit flies attractant. Basil plant parts were extracted using Soxhlet apparatus, steam and water distillation, the highest produced oil percentages from flowers and leaves were (5.75 and 3.03%) respectively, while, the lowest percentages were obtained from the seed and stem (0.02 and 0.21%) respectively. The produced oil was analyzed using GCMS, Methyl Eugenol was found as one of 32 compounds produced. The raw plant parts (leaves and flowers) were baited and used into two forms (powder and paste) to test the basil efficiency in fruit flies attraction. The basil traps catch was too low compared with that of the control traps. The Methyl Eugenol extracted from basil plant was verified and compared with the standard synthetic Methyl Eugenol. The extracted Methyl Eugenol from basil

plant when used in the insect traps gave lower catch of fruitflies numbers than the synthetic Methyl Eugenol traps, but the difference was not significant.

Key words: *Ocimum basilicum* , Attractant . Fruitflies.

EFFECT OF ORGANIC PLANT NUTRIENT MANAGEMENT ON GROWTH, YIELD AND POST HARVEST STATUS OF BROAD LEAF MUSTARD (*BRASSICA JUNCEA* VAR. *REGOSA*)

B.P. BHATTARAI AND P.BUDHATHOKI

Himalayan College of Agricultural Sciences and Technology/PU, Kathmandu, Nepal

The field experiment was conducted to evaluate “Effect of organic plant nutrient management on growth, yield and post harvest status of Broad Leaf Mustard (*Brassica juncea* var. *rugosa*)” was carried out in Dakshinkali municipality-2 , Kathmandu , Nepal in 2017. There were five treatments viz. T₁ (24 t.ha⁻¹ FYM), T₂ (8 t.ha⁻¹ vermicompost), T₃ (4 t.ha⁻¹ poultry manure) , T₄(12 t.ha⁻¹ compost) and T₅ (Control) with three replication. The experiment was laid out in a Randomized Complete Block Design. The results showed that maximum plant height (36cm), number of leaves per plant (13) , leaves size (868.89cm²) and leaf canopy (0.053m³) were found in with the treatment T₂(8 t.ha⁻¹ vermicompost). The yield per plant (0.149kg/plant), yield per plot (4.37 kg/plot) and yield per hector (8.65kg/ha) were found maximum in T₂ (8ton/ha vermicompost). The maximum vitamin C contained in BLM was found in the treatment T₂ (8 t.ha⁻¹ vermicompost) (48mg/100gm). Similarly in case of post harvest status, the maximum shelf life period in BLM was observed in T₂ (8 t.ha⁻¹ vermicompost) and T₄ (12 ton/ha compost) (9 days each). In terms of organoleptic test, maximum acceptance was found in T₂ (8 t.ha⁻¹ vermicompost) (7.5).

Key world: Organic, FYM , vermicompost , poultry manure , growth , yield

EVALUATION OF SOME WHEAT GENOTYPES UNDER SOWING DATES AND NITROGEN LEVELS: 1. GROWTH AND STRAW YIELD

EL-SAYED M. GHEITH, AHAMAD ABDEL SHAHEED, OLA Z. EL-BADRYANDSAFAA A WAHID

Agronomy Department, Faculty of Agriculture, Cairo University, Egypt

A study on the response of five wheat genotypes (Sids 1 and Gemmiza 9 from Egypt, L.R.-52 from Sudan, L.R.-62 and L.R.-67 from Yemen) to three sowing dates (25th November, 10th and 25th December) and two nitrogen levels (120 and 240 kg N/ha.) was conducted at the Agricultural Experimental and Research Station, Faculty of Agriculture, Cairo University, Egypt during 2011/2012 and 2012/2013. The experiment was laid out in RCBD in a split plot design, placing sowing dates in the main plots, nitrogen levels in the sub plots and genotypes in the sub sub-plots with three replications. Sowing dates had significant effect on the number of days to 50% heading, flag leaf area, plant height and straw yield in both seasons. The highest values of the previous traits were obtained at early sowing on 25th November in both seasons. All the studied traits significantly increased by increasing nitrogen levels up to 240 kg N/ha. The genotype L.R.-67 emerged 50% of its heads earlier, Gemmiza 9 and L.R.-67 gave taller plants, L.R.-62 produced the highest number of tillers, whereas Gemmiza 9 and L.R.-62 produced the highest straw yield in both seasons. The earliest heading and the largest flag leaf area were obtained from sowing on 25th December at 240 kg N/ha. in both seasons. Late sowing (December) and low nitrogen applications significantly declined the yielding capacity of the wheat genotypes. Gemmiza 9 and L.R.-62 performed better in term of straw yield as compared to the other genotypes.

Key words: Wheat, sowing dates, N levels, genotypes.

MANAGEMENT OF FRUIT FLIES IN SHENDI AREA, SUDAN FOR SUSTAINABLE MANGO PRODUCTION

FAIZA M. A. MAGID¹, AMANI M. KHAIR²

Department of Pests and Plant Health, College of Agriculture, University of Bahri, Khartoum North, Sudan. Department of Zoology, Faculty of Science and Technology, Shendi University.

Mango (*Mangifera indica*) is universally considered as one of the most important. Fruit crops in tropical and subtropical areas in the world. In Sudan, more than 40 commercial mango cultivars of international recognitions for their excellent quality grown in different regions of the Sudan. However, in recent years production targets have been seriously hampered, mainly, because of the Sudden and persistent out breaks of fruit flies infestations which exceeded 80% in some of the seriously effected areas This study was conducted at Shendi area in the River Nile State (one of the main mango production areas in Sudan) to investigate the role of cultural practices as a part of integrated pest management to control fruit flies. Three orchards within the study area were chosen and subjected to a package of cultural practices -included hoeing, flooding, orchard cleaning and early harvesting of fruits before ripening. Results showed a highly significant difference in the level, percentage and degree of infestation for the different mango varieties grown on the study areas. The reduction percentage

ranged from (49-73%, 57.3-99 %),(44.9-72%,64.6-83.4) and (29-55%49.6-75.4)% for the three parameters respectively for the two seasons. This result was in accordance with the number of trapped fruit flies per month. High performance of cultural practices on lessening infestation levels of fruit flies give it the priority to be applied as an effective method in management of fruit flies to avoid overlapping of generations and to reduce the growth rate of insects' population.

Sudan is a wide country estimated 1,765,048 Km² with population 41,511,526 in 2018 (World Bank 2018), the arable land estimated to reach 83.333.3 million hectares. Different climatic zone enable the production of many crops especially horticultural crops through out the year. Agriculture sector in Sudan is the most important source of income and livelihood for 60 – 80% of the population. Mango (*Mangifera indica*) is universally considered one of the most important Fruit crops in tropical and subtropical areas in the world. In Sudan, more than 40 commercial mango cultivars of international recognitions for their excellent quality grown in different regions of the Sudan. However, in recent years production targets have been seriously hampered, mainly, because of the sudden and persistent outbreaks of fruit flies infestations which exceeded 80% in some of the seriously effected areas. In the year , 2007 the fruit flies problem became so severe to the extent that they were up graded and added to the list of the notorious national pests of the Sudan. There is always a growing demand locally regionally and globally for fruits and vegetables and thriving export and import trade on these commodities. Sudan is producing fruits and vegetables in, almost, all the comers of the country and its center, especially in areas along the Nile valley and areas where adequate irrigation water is available. The modest production of Sudan fruits and vegetables has always been far less than the local or the regional demand. Consequently there is a serious attempt to increase the production to meet the ever increasing demand . However, in recent years production targets have been seriously hampered, mainly, because of the sudden and persistent outbreaks of fruit flies infestations which exceeded 80% in some of the seriously effected areas. In the year , 2007 the fruit flies problem became so severe to the extent that they were up graded and added to the list of the notorious national pests of the Sudan.

YIELD AND QUALITY OF RHODES GRASS (*CHLORIS GAYANA L. KUNTH.*) AS AFFECTED BY SEED RATE AND NPK FERTILIZER APPLICATION

FATHI I. A. BRIMA¹ AND AWAD O. ABUSUWAR²

¹ Department of Crop Science, College of Agriculture, University of Bahri, Khartoum, Sudan

² Departments of Agronomy, Faculty of Agriculture, University of Khartoum, Khartoum, Sudan

* Fathi I. A. Brima, Department of Crop Science, College of Agriculture, University of Bahri, Khartoum – Sudan.

A field experiment was conducted for one season (2006/2007) at the Demonstration Farm of the Faculty of Agriculture, University of Khartoum, Shambat, Sudan, to investigate the effect of seed rate and NPK fertilization on yield and quality of Rhodes grass forage (*Chloris gayana* L. Kunth) cv. Finecut. The treatment consisted of three seed rates (SDR₁, SDR₂ and SDR₃) namely 5, 10 and 15 kg/ha and three NPK fertilizer levels (F₀, F₁ and F₂) namely 0, 120 and 240 kg/ha respectively. NPK fertilizer compound N₁₇ P₁₇ K₁₇. The experiment was laid out in a Factorial CRBD with four replications. The results showed that seed rate significantly increased forage fresh and dry yield. NPK fertilization significantly increased forage fresh and dry yield. Neither seed rate nor NPK fertilization were significantly affected crude protein and fiber content of leaves and stems of Rhodes grass, but the increase in seed rate and fertilizer levels slightly increased crude protein and decreased fiber percentage. Seed rate × NPK fertilization interaction showed significant effect on crude protein and crude fiber contents. The highest protein percentage obtained under SDR₂ with highest fertilization level (F₂), and lowest value obtained under SDR₁ with (F₁) fertilization and SDR₁ under control of fertilizer treatment (F₀). Regarding crude fiber, highest value obtained under SDR₂ with F₁ and SDR₃ under control treatments of fertilization (F₀).

Keywords: Rhodes grass, seed rates, NPK fertilizer, yield, quality

EFFECT OF ROOT AND FOLIAR APPLIED FERTILIZER ON YIELD OF POTATO AND CABBAGE

K.M.S. KODIKARA¹, H.M.M.S.K. SENEVIRATHNE², B.W.P.K. SAMARAWEEA¹ AND I.P.YAPA²

¹ Regional Agriculture Research and Development Centre, Diyatalawa Road, Bandarawela, Sri Lanka.

² Sabaragamuwa University of Sri Lanka, Belihuloya, Sri Lanka.

An investigation was conducted to estimate the absorption efficiency of root and foliar applied nutrients on cabbage and potato in Regional Agriculture Research and Development Centre, Bandarawela (6°49'59.99" N 80°58'59.99" E), Sri Lanka during 2014 and 2015. Experiment was conducted in 1x1x0.2 m wooden boxes filled with soil less medium (Cair dust based) and maintained in protected environmental conditions. A complete nutrient mixture (Albert solution) was applied directly into plant roots, sprayed into leaves to drain out the excess into medium, foliar application only without allowing draining out to medium and compared with no fertilizer control. Experiment was laid out in CRD with three replicates. Plant growth and yield were recorded and Nutrient Use Efficiency (NUE) was calculated. Results showed that, growing medium pH and EC

were varied with initial values and after the crop pertinent to fertilizer application methods and root applied treatment showed higher variations. Root application of plant nutrients was recorded significantly higher yield than foliar application. Significant yield increment recorded by root absorbed nutrients from drained portion of fertilizer to growing medium than only foliar applied treatment according to plant growth and yield of cabbage and potato. It reflected superior NUE in root applied plant nutrients and always cabbage shows higher NUE than potato. Foliar application was not able to fulfill the total plant nutrient demand of cabbage and potatoes.

Key Words – Cabbage, Fertilizer, Foliar application, Potato, Root application

GROWTH AND PRODUCTIVITY OF BARELY (HURDIUM VULGARE L.) AS AFFECTED BY SOWING METHODS AND NITROGEN FERTILIZER LEVELS

OLA Z. EL-BADRY AND EL-SAYED M. GHEITH

Faculty of Agriculture, Cairo University, Egypt Department of Agronomy,

Growth and productivity of barely (*Hurdium vulgare* L.) as affected to two sowing methods (drilling and broadcasting) and three nitrogen levels, i.e. 60, 80 and 100 kg N/fed. (one feddan = 4200m²) were studied at the Agricultural and Experimental Research Station at Giza, Faculty of Agriculture, Cairo University, Egypt during two successive winter seasons 2015/2016 and 2016/2017. The experiments design was split-plot in randomize complete pluck design in four replications. Results indicated that both of sowing method and nitrogen levels significantly affected all growth characters, except leaf area index in the second season, as well as grain yield and its related favorable, except spike length and grain weight/spike, in both seasons. Increasing nitrogen levels up to 80 kg N/fed. caused an obvious increase in net assimilation rate, plant height, number of spikes/m², spike length, weigh of grains/spike, grain yield, straw yield and harvest index. On the contrary, number of days to 50% heading, leaf area index and crop growth rate produced the maximum values at 100 kg N/fed. Drilling method exceeded broadcasting in all studied characters in both seasons. The interaction had significant effect on leaf area index, number of spikes/m² and grain yield which produced the highest values with using drilling method and application of 100 kg N/fed. and 80 kg N/fed., respectively in both seasons. It could be concluded that planting barley with drilling method and application of 80 kg N/fed. are the optimum for increasing barley production under the experimental site and the same conditions.

Key words: Barley, sowing method and nitrogen fertilizer.

ENHANCING MICRONUTRIENTS IN SOIL THROUGH THE USE OF IRON SLIME

S P VISTA

Nepal Agricultural Research Council, Mountain Agriculture Research Institute, Jumla, Nepal

Micronutrient deficiencies are critical in South East Asian Countries and huge amount of government annual budget in health sector has been continuously spent in Zinc and Iron supplement in Bangladesh, Nepal, India, etc. for many years. Micronutrient deficiency in the soils of this region is pertinent and therefore cheaper sources for micronutrient supplementation should be explored. In this line, a research was conducted using waste product of iron and steel industries-iron slime as source of micronutrient and evaluated in cabbage and rice both under green house and field condition. Results in rice growing soil under greenhouse condition showed that the concentration of available Zn was found extremely high in all the treatments and stages of crop growth. Irrespective of treatments, DTPA extractable Zn increased at harvesting stage of rice. Addition of iron slime to soil in proportion of 1:1 showed better availability of Zn than the soil amended with 2:1 proportion of iron slime. Similarly, there was higher concentration of available Cu in both sole soil and iron slime systems. But in case of rice plant, higher amount of total Fe and Cu was observed in rice plant grown with iron slime. With increasing proportion of iron slime, the total Fe and Cu were also found increased. In the soil growing cabbage under greenhouse condition, the concentration of available Zn in iron slime was found of higher order under all the treatments and stages of crop growth. Higher amount of available Cu and available iron content were observed in iron slime throughout the period of experimentation. Addition of iron slime in soil influenced soil available Fe to a great extent. Higher the amount of iron slime added to the soil, higher was the amount of available Fe in the system. With respect to the period of experimentation, the available iron was of higher order at the last stage of the experiment. The total micronutrients content in cabbage plant especially Fe, Mn Cu and Zn were found to be of higher order in cabbage grown in sole iron slime and iron slime treated soil. The total Fe content in cabbage was directly proportional to the amount of added iron slime. Under field condition in rice crop, the total Zn content increased progressively as the crop tended to mature. Higher concentration of Zn was obtained at harvesting stage. Sole iron slime treated soil showed least amount of total Mn in rice plant. Irrespective of treatments, the total iron increased significantly with the period of experimentation up to dough stage of crop growth and then decreased at harvesting stage. Plots amended with iron slime showed higher amount of total iron in plant samples. Addition of iron slime to soil increased micronutrient uptake by rice grains. Comparatively higher amount of Fe and Zn than that of Mn and Cu

were taken up by rice grains. Practically very lower amount of Cu is taken by rice grains. Very little variation was recorded in uptake of micronutrients under different iron slime added treatments. However, it was recorded that grains contain appreciable amount of Zn, Fe and Mn but contained very less amount of Cu.

Having studied all the parameters by treating soil with iron slime, it could be concluded that for enhancing micronutrient in soil system, application of iron slime can be a cheap and environment friendly option.

Keywords: Iron slime, Micronutrients, Greenhouse experiment, Soil, etc.

NEED OF COMMUNITY BASED ANIMAL HEALTH CARE (CBAHC) FOR ANIMAL HEALTH DELIVERY SYSTEM

¹SHEETLA PRASAD VERMA AND ²ADESH KUMAR VERMA

¹Associate Professor, Department of A.H. and dairying ² Assistant Professor, Department of Agricultural Extension
Kulbhaskar Ashram P. G. College, Allahabad

Livestock health service delivery requires massive infrastructure by the government. However, the existing infrastructure is not adequate considering the vastness and the population. As such, livestock health service delivery—like other services—, in many countries privatization as part of an international re-structuring for economic development. One important initiative to refocus livestock health service delivery has been the introduction of community based animal health service (CBAHS). The CBAHC is an approach aimed at delivering service that are controlled by the community as opposed to the conventional government controlled or central service delivery approach. It is the delivery of animal health service by selected members of the community who are trained to handle basic animal health care issues at village level. These trainers are called as CAHWs. For sustainability, they are linked to a drug supply system as well as a referral system with veterinary professionals. The CBAHS has now become very popular in many countries. This approach has also been used in the provision of animal health care service in India.

CHARACTERIZATION AND CLASSIFICATION OF SOILS OF SOHAG-RED SEA ROAD SIDES, EASTERN DESERT, EGYPT

ALI R. A. MOURSY, A.ABDEL GALIL, M.S.IBRAHIM, A.A. ABDEL HADY

1.Soil and water Dept., Faculty of Agriculture, Sohag University, Egypt

2.Soil Dept., Faculty of Agriculture, Cairo University, Egypt

An investigation was carried out to characterize and classify the soils of area about 204 km² where lies between 26° .75, 26° .65 latitudes (N) and 32° .70, 32° .90 longitudes (E) of Sohag-Red Sea Road-sides, Eastern Desert, Egypt. Twelve representative pedons were chosen based on six mapping units identified from the DEM extracted from the Landsat 8 ETM+ satellite image. All pedons were moderate to deep in depth, well drained, slightly to strongly alkaline in soil reaction (7.6-8.4), slightly to moderately saline (3.5- 16 dS m⁻¹), low in organic matter (0.1-0.4%), CEC is low (1.5-7.0 cmol (p+) kg⁻¹), Calcium Carbonates ranged from (1.2-18.2%). Regarding nutrients, the soils were low in available N (1.5-30kg ha⁻¹), low in available P 1.0-9.0kg ha⁻¹), medium to high in available K (100-680 kg ha⁻¹). Further, the soils were low to moderate in available Fe, Mn, Zn and Cu. Soil classification of the investigated area done according to the field survey, morphological description and soil analyses. Two orders of Entisols and Aridisols were recognized representing three subgroups Typic Torriorthents, Typic Torripsammets and Typic Haplocalcids. These results can be used by decision makers to focus on prospective agricultural areas and to achieve land reclamation and better agricultural production.

IN VITRO AND IN VIVO STUDIES OF SYRIAN NATIVE ISOLATES OF *TRICHODERMA* SPP. AGAINST ROOT KNOT NEMATODE *MELOIDOGYNE INCOGNITA* ON TOMATO

RAMI KASSAM¹, DR. UMA RAO², DR. NADA ALLOUF³, DR. MAYSA YAZIJI⁴

^{1,2}Division of Nematology ICAR-IARI, New Delhi, India

³Division of Plant Protection, ⁴Division of Plant Biology, Tishreen University, Syria.

Seven isolates of three *Trichoderma* species *T. viride*, *T. longibrachiatum* and *T. harzianum* were isolated and tested in order to identify the most appropriate native strains to control root knot nematodes (RKN) under laboratory and semi-field conditions comparing with commercial imported product of *Trichoderma*. Results showed that all native isolates had a potential virulence to parasite some stages of RKN. *T. harzianum* isolate showed highest rate of parasitism on egg masses, the eggs inside them and female stages 95, 43.7% & 90.6% respectively, compared with the commercial product 39.8, 26.2% & 63.2% respectively, this isolate also damped eggs hatching of (RKN) to 5.75% compared with commercial product and control 41.50 & 51% respectively. Three isolates, which had proved its superiority in vitro, was evaluated against

Venue : Sardar Patel Auditorium, Swami Vivekanand Subharti University, Meerut (U.P.) India 20-22 October, 2018

Meloidogyne incognita in vivo on tomato seedlings under greenhouse conditions, after 30 days the outcomes indicated the ability of *T. harzianum* isolate to decrease the numbers of knots and egg masses per root, but after 90 days the *T. longibrachiatum* isolate exhibited significantly reducing in knots and egg masses' numbers per root 181.30, 166.50 respectively comparing with the commercial product 332.26, 305.76 and comparing with control 493.61, 488.94 respectively. In addition, *T. longibrachiatum* isolate significantly improved plant parameters especially shoot wet weight 198.66 g comparing with the commercial product and control 161.06, 123.86 g respectively.

REJUVENATION OF OLD SENILE ORCHARDS TO RESTORE FRUIT PRODUCTION

NAZIR AHMAD GANAI, KHALID RASOOL, ANGREJ ALI AND AMIT KUMAR¹

Division of Horticulture, FOA, SKUAST-Kashmir, Wadura Campus, Sopore (J & K)

¹*Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K)*

Old and senile orchards that have lost their production potential are a matter of great concern for orchardists. The trees which have become old with dense tree canopy are less productive and produce fruits with inferior quality. This is attributed to overcrowded and intermingled branches and meager foliage, allowing poor light availability to growing shoots within the canopy and renders them uneconomical. There are several reasons for the low productivity and quality of fruit trees which can be compensated by adopting rejuvenation technique. It has been found that replantation of old orchard sites is also cumbersome as it leads to drastic economic loss due to uprooting of old trees combined with poor establishment of new plants on old orchard sites *vis-a-vis* its juvenile period. Thus every effort should be made to invigorate old and neglected trees in order to restore their production potential. However, it must be noted that every tree cannot be rejuvenated. For instance it will be useless to invigorate a tree which is too old, suffering from an inherent virus disease or growing poorly as it has been grown on poor soil, hard pan or rock. Rejuvenation produces best results on trees which have otherwise healthy root system, good vigour but are unproductive because of defects in pruning or cultural practices. The technique of rejuvenation will be different for every large apparently healthy tree, stunted tree and aged and less vigorous tree. Reduced crop productivity in fruit trees because of repeated planting of the same or closely related species has been definitive and recognized by various names including soil sickness, soil exhaustion, and replant disorder and replant problem. In temperate fruits replant problem and replant disorder have been attributed to diminished soil fertility, degraded soil structure and residual herbicide activity. Therefore, retention of juvenility though a tedious practice is important in plant propagation to restore productivity and fruit quality and thus needs to be adopted scientifically to avoid tree mortality or excessive damage.

OPTIMIZING DRIP IRRIGATION FOR CAPSICUM USING CROPWAT MODELING UNDER PROTECTED POLYHOUSE CONDITIONS

NIGHAT MUSHTAQ, NAZEER AHMED¹, KHURSHEED HUSSAIN² AND SAJAD AHMAD BHAT³

Division of Vegetable Science, SKUAST-Kashmir, Shalimar Campus ¹*Hon'ble Vice Chancellor SKUAST-Kashmir, Shalimar Campus* ²*Division of Vegetable Science, SKUAST-Kashmir, Shalimar Campus* ³*Division of Basic Science and Humanities, SKUAST-Kashmir, Shalimar Campus*

Due to overexploitation of available water resources, it has become very important to optimize water requirements for management of water resources. The study aims to develop an optimal irrigation scheduling, to increase crop yield under water scarcity conditions. The crop water requirement was found to be 560.7 mm and irrigation requirement 540.2 mm. On refilling soil to field capacity with irrigation at critical depletion gave a yield reduction of about 0 %. The research shows that the irrigation management model can effectively and efficiently estimate the crop water requirements. The model, that calculates evapotranspiration and crop water requirements, allows the development of recommendations for improved irrigation practices, the planning of irrigation schedules under varying water supply conditions and yields reduction under various conditions.

AGRONOMIC BIOFORTIFICATION

YOGITA

Agronomy Department, CCS Haryana Agricultural University, Hisar

Nearly 2 billion people suffer from iron (Fe), zinc (Zn) and/or other (multiple) micronutrient deficiencies in the world. Hidden hunger or micronutrient deficiency retards the growth and development of both crops and humans. Agronomic biofortification is the application of mineral micronutrient fertilizers to soils or plant leaves. Through agronomic biofortification micronutrient concentration in edible crop products can be enhanced and indirectly it will aid in improving human health. There is evidence that agronomic biofortification can increase yields and the nutritional quality of staple crops. Micronutrient fertilization is found to be effective when combined with NPK, organic fertilizers and improved crop varieties, accentuating the importance of integrated soil fertility management. Application of micronutrient-enriched fertilizers is considered to have minimal negative environmental impact.

COMBINED APPLICATION OF MANURES AND FERTILIZERS ON THE GROWTH OF YOUNG TEA PLANTS (CAMELLIA SINENSIS (L.) O. KUNTZE) INTER-PLANTED IN ARECANUT GARDEN**ANJANEYULU*, H. BHATTACHARJEE AND P. S. MEDDA***Department of Plantation Spices Medicinal and Aromatic Crops, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, Nadia, West Bengal 741252.*

Combined application of manures and fertilizers on the growth of young tea plants (*Camellia sinensis*(L.) o. kuntze) inter-planted in arecanut garden, was investigated at Instructional plots of the Department of Plantation Crops and Processing, UBKV, Pundibari, West Bengal during March, 2016 to May, 2017. The experiment was conducted with five treatments (T_1 : Control), (T_2 : FYM@2.0kg+1/2RDF), (T_3 : Vermicompost@1.0kg+1/2RDF), (T_4 : FYM@2.0kg+RDF) and (T_5 : Vermicompost@1.0kg+RDF) with four replications and laid out in Randomized Complete Block Design (RCBD). Fertilizer is one of the major agro-inputs contributing to the cost of production and productivity in tea plantation, for proper maintenance of the health of tea bushes and to obtain high yield a well-balanced fertilization is necessary throughout the year. For maintaining the soil health integration of various factors like physical, chemical and biological properties of soil, climate, addition of organic matters are vital for achieving maximum return from the investment and productivity of the soil, so that the use of integrated nutrient management is very important, best approach to maintain and improve soil fertility thereby to increase crop productivity in an efficient and environmentally, without sacrificing soil productivity of future generations. Growth parameters were recorded from 30 to 360 days after planting. Experimental results were not statistically significant difference among the treatments on 30 days after planting. The treatment T_5 : VC+RDF has given best results regarding the growth parameters like minimum number of days taken to reach pluckable height of 55cm (98.00), maximum number of leaves (75.5 per plant), number of branches (15.55 per plant) and plant girth (29.43 mm) at collar region, followed by T_4 : FYM+RDF and T_3 : VC+1/2 RDF whereas the minimum results was recorded by T_1 : control. Results were varied significantly with application of manures and fertilizers inter planted in arecanut garden among the treatments from 60 to 360 days after planting.

Key words: Growth, Integrated nutrient management, Form yard manure and Vermicompost.

SURVEY OF RICE SHEATH ROT DISEASE AND ASSESSING THE GROWTH AND PATHOGENICITY OF *SAROCLADIUM ORYZAE*.**VENGADESHKUMAR AND T. MEERA***Department of Plant Pathology, Faculty of Agriculture, Annamalai University, Annamalai Nagar, Chidambaram, Tamil Nadu, India-608 602.*

Rice sheath rot is caused by *Sarocladium oryzae* also one of the major factor of rice production constrain. Hence, the present study was conducted with an objective to assess the prevalence and incidence of rice sheath rot disease in different regions of Nagapattinam district, Tamil Nadu, India and assess the cultural characters and pathogenic variability among the isolates of *S. oryzae*. The survey clearly revealed that the disease incidence ranged from 12.32 to 30.43 per cent showing the endemic nature of the disease. Among the media tested both solid and liquid, PDA and PD broth was found to be the best in supporting the mycelial growth (4.55cm) and mycelial dry weight (317.34mg) of the pathogen. Among the isolates SO_{17} was found as the most virulent which recorded maximum per cent disease incidence (58.33%) with maximum lesion size 39.40 mm length and 5.31 mm width on rice variety ADT 39. Also, the study proved that grain inoculation method is a best in taking infection and affecting crop among the different methods of artificial inoculation tested.

CONSORTIUM OF FUNGAL AND BACTERIAL ANTAGONIST FOR THE MANAGEMENT OF STEM ROT OF CLUSTER BEAN**A. MUTHUKUMAR***Department of Plant Pathology, Faculty of Agriculture, Annamalai University, Annamalai Nagar-608002, Chidambaram, Tamil Nadu, India.*

Cluster bean (*Cyamopsis tetragonaloba* L.) which is known as Guar means "cow food" (Hindi) belonging to the family leguminosae. It is an annual, arid and semi-arid legume crop. The crop has got a special importance because of gum content in its seed. The crop is subjected to be infected by several fungal diseases. Among these, stem rot caused by *Sclerotium rolfsii* Sacc. cause 50-70% mortality of seedlings in the field. The objectives of the present study were isolation and identification of antagonistic microorganisms from native soil and tested for its efficacy against *S. rolfsii* *in vitro* and *in vivo*. Results of the *in vitro* studies reveals that *T. harzianum* isolate 4 (THM) recorded maximum growth inhibition (68.10 per cent) of pathogen by using dual culture technique. Of the bacterial antagonists tested, *P. fluorescens* isolate 3 (PFV) recorded the maximum inhibition zone (13.33 mm)

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

with a minimum mycelia growth (23.00 mm) of *S. rolfsii* over control. Results of the *in vivo* studies reveals that the combined application of selected isolate of talc-based formulation of *T. harzianum* + *P. fluorescens* (ST+SA) and challenge inoculated with *S. rolfsii* to soil recorded maximum plant height (110.33 cm), pod length (9.8 cm) and highest pod yield (8.0 t/ha) of cluster bean.

EFFECT OF DIFFERENT MULCHES FOR MANAGEMENT OF OKRA FLEA BEETLE (*PODAGRICA BOWRINGI*) Baly

A. P. KELKAR*, A. Y. MUNJ, V. S. DESAI AND G. M. GOLVANKAR

Department of Entomology, College of Agriculture, Dapoli, Balasaheb Sawant Konkan Krishi Vidyapeeth, Dapoli, Dist- Ratnagiri 415712 (M.S.)

The research was conducted to evaluate different mulches for management of okra flea beetle (*Podagrica bowringi*) Baly at Agronomy farm, College of Agriculture, Dapoli during *kharif* 2017. The observations recorded at 1st week after first soil application indicated that the treatment (M₃) black polythene mulch (7.17) was found to be effective treatment. At 2nd week, (M₃) black polythene mulch treatment recorded (6.97 shot holes/three leaves/plant). At 3rd week the treatment (M₃) black polythene mulch was found to be the effective treatment which recorded 7.17 shot holes/3 leaves/ plant. At 1st week after second soil application indicated that the treatment black polythene mulch (M₃) was found to be effective treatment (8.70 shot holes per three leaves per plant). At 2nd week, minimum numbers of shot holes were recorded in the treatment (M₃) black polythene mulch (9.50 shot holes/3 leaves/ plant). At 3rd week revealed that (M₃) black polythene mulch, (M₂) silver polythene mulch and (M₁) transparent polythene mulch recorded 8.60, 9.77 and 10.11 shot holes per three leaves per plant, respectively and all these treatments were at par with each other. There was same trends observed during third soil application.

Key words: Mulches, *Podagrica bowringi*, Flea beetle, transparent mulch, Silver mulch, Black mulch etc.

STUDIES ON SEEDS MYCOFLORA OF *WITHANIA SOMNIFERA* (L.) DUNAL DURING PRE HARVEST, POST HARVEST AND STORAGE CONDITIONS ALONG WITH BIOCHEMICAL ESTIMATIONS OF INFECTED STORED SEEDS

A. R. ANSARI¹ AND ADEEBANWAR²

¹Govt. Degree College Gairsain, Chamoli, Uttarakhand, India, ²M. B. Govt. P. G. College, Haldwani, Nainital, Uttarakhand,

Withania somnifera (L.) Dunal is an important medicinal plant belonging to family Solanaceae. In order to screen the succession of mycoflora associated seeds of *W. somnifera*, seeds were obtained at pre harvest, post harvest and at storage conditions. In total 36 fungal species were isolated by using three incubation methods i.e. agar plate method, standard blotter paper method and deep freezing method. A qualitative and quantitative differences were recorded with seeds obtained from three different stages. A significant changes in the mycoflora was noted with the advancement of age. In general, the number of fungal species associated were found to be the highest in storage seeds followed by post harvest seeds and then in pre harvest seeds. Fungal association with seeds not only affected seed health but also caused loss in nutrients. Healthy and infected seeds of *W. somnifera* were also evaluated quantitatively for their protein, carbohydrates and total alkaloid contents. A comparative study revealed a reduction of 1.70%, 2.74% and total 15.39 mg/kg in protein, carbohydrate alkaloid contents respectively in infected seeds in comparison to their healthy counterparts.

DROUGHT ASSESSMENT UNDER CLIMATE CHANGE BY USING NDVI AND SPI FOR MARATHWADA

A. U. WAIKAR^{1*}, U. M. KHODKE² AND P. S. PAWAR³

¹Dept. of Irrigation and Drainage Engineering, College of Agricultural Engineering & Technology, ²AICRP on Irrigation Water Management, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani-431402

Drought is considered to be the most vulnerable natural hazards which affect large amount of people. The impacts of drought are nonstructural and spread over a large geographical area damaging the life of human beings. Marathwada the most vulnerable region to frequent droughts located in central India was selected as the study area. The spatial and temporal data of region required for the drought analysis was collected from meteorological stations and satellite data Resourcesat-1 Awifs was procured from NRSC, Hyderabad. GIS was used to analyze the spatial and temporal variation of drought across the study area to determine the drought affected area accurately so as to provide effective drought proofing. Meteorological drought analysis was performed by Standardised Precipitation Index (SPI) to determine drought severity classes. Using NDVI analysis, Marathwada region is classified into severe, moderate, mild drought classes. Frequencies of various drought classes were determined by using SPI. Drought classification based on SPI indicated that majority of the region suffered from extreme to severe drought conditions for 2 to 3 times during study period. Based on the drought risk

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

area map was prepared for Marathwada region.

AZOLLA AN ALTERNATIVE GREEN FODDER FOR LIVESTOCK

AARADHANA CHILWAL¹, SHIVANI KOTHIYAL² AND NEHA JOSHI³

Punjab Agricultural University, Ludhiana, Punjab, 141004, Navsari Agricultural University, Navsari, Gujrat, 396450

India has the largest livestock population and is first in terms of milk production in the world too. But the average milk productivity has become stagnant and needs to be improved. Nowadays greatest problem that Indian livestock farmers are facing is the shortage of fodder due to cultivation of high yielding varieties, shrinkage of grazing lands, urbanization, replacement of traditional sources of cattle feed like coarse grains and oilseeds by cash crops etc. Under such pressure a number of steroids, synthetic antibiotics and vitamins are used to increase production of milk, meat, egg etc. These chemicals accumulate in the human body, through the consumption of animal products and could cause various degenerative diseases. If we can substitute the cattle feed with natural feeds that are rich in useful nutrients, it will be of great importance for human and animal health. Hence Azolla can be used as unconventional high potential feed for non-ruminants. Azolla is highly beneficial in terms of - good source of protein (contains almost all essential amino acids), vitamin A, precursor beta-carotene, vitamin B₁₂, growth promoter intermediaries and minerals like calcium, phosphorous, potassium, ferrous, copper, magnesium etc., contains 25-35% protein, 10-15% minerals and 7-10% of amino acids, bio-active substances and bio-polymers on dry weight basis, the carbohydrate and fat content is very low, its nutrient composition makes it a highly efficient and effective feed for livestock as livestock easily digest it, owing to its high protein and low lignin content, and quickly grow accustomed to it, easy and economical to grow, Azolla as feed substitute shows overall increase of milk by 15-20%, Azolla feeding improves the quality of milk and animal health, improves the weight of broiler chicken and increases the egg production in case of layer and it can also be feed to sheep, goat, pig and rabbit as feed substitute for better growth. By this way, Azolla can be used as a good substitute for the cattle feed. It is palatable and cheapest nutrition to cattle, buffaloes, ducks, chickens, pigs, goats, sheep and rabbits. Cultivation and harvesting of Azolla is also very easy. Moreover, the bio-product of Azolla cultivation after 6 month can be used as bio fertilizer in organic farming or fields. Azolla cultivation is thus a sustainable way out for fodder crises

AMELIORATION OF TEMPERATURE STRESS DAMAGE IN FRUIT CROPS

ABHAKUMARI, RUBY RANI, ANKITA AMAN, POOJA KUMARI

Department of Horticulture (Fruit and Fruit Technology), Bihar Agricultural University, Sabour, Bhagalpur-813210, India

Any deviation from this optimal condition of any factor essential for its growth will lead to aberrant change in physiological processes and due to this plant body will experience tension and this state can be referred as plant under stress. Abiotic stress is defined as the negative impact of non-living factors on the living organisms in a specific environment. This stress may have adverse effect on germination, photosynthesis, respiration, water relations and membrane stability, may also modulate levels of hormones and primary and secondary metabolites. Among the abiotic environmental factors temperature is the most important factor which significantly affects life processes of all organisms. Temperature stresses experienced by plants are usually classified into three types: high temperature stress, chilling stress (occurring at temperatures below freezing) and freezing stress (occurring at low temperatures above freezing). Both low and high temperatures affect plant growth and development at whole plant level, tissue and cell level and even at sub-cellular level. Temperature variation may affect morphology, anatomy, phenology and plant biochemistry at all levels of organization. Direct injuries due to high temperatures in plants include protein denaturation and aggregation, and increased fluidity of membrane lipids. Indirect high temperature injuries include inactivation of enzymes in chloroplast and mitochondria, inhibition of protein synthesis, protein degradation and loss of membrane integrity. Low temperature stress during reproductive development induces flower abscission, pollen sterility, pollen tube distortion, ovule abortion and reduced fruit set, which ultimately lowers yield. Temperature stress is a multigenic trait and a number of approaches are being used to alleviate the effect of temperature stress in fruit crops: addition of low concentration of inorganic salt, osmoprotectants, signalling molecules (growth hormones), oxidants (H₂O₂), preconditioning of plants, exogenous application of Ca²⁺ (CaCl₂), organic compounds (glycinebetaine and polyamines), plant nutrients like macronutrients (nitrogen, potassium, calcium and magnesium), micronutrients (boron, manganese, and selenium) and salicylic acid, mycorrhizal efficacy.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**FOLIAR APPLICATION OF MICRONUTRIENTS ON GROWTH AND YIELD OF AONLA (EMBLICA OFFICINALIS GAERTN.) CV. NEELUM****ABHIJITH, Y.C1*, DINAKARAADIGA, J2., HONNABYRAIAH, M.K3., KISHOR, H4 AND SINDHU, C5**

Department of Fruit Science, College of Horticulture, GKV campus, Bengaluru, India, Principal Scientist (Hort-Fruit Science), ICAR-DCR, Puttur-574 202, Department of Fruit Science, College of Horticulture, Bengaluru, Aeroponics Centre, PRS Horticulture Farm, Chickaballapura, Karnataka, India 5Aeroponic, Division of Food Science and Post Harvest Technology, IARI, Pusa Campus, New Delhi

Aonla (*Embllica officinalis* Gaertn.) belongs to family Euphorbiaceae and is popular as backyard fruit throughout the country. Owing to its hardy nature, suitability to waste land, high productivity, high nutritive and therapeutic value, it became an important fruit for small and marginal farmers. Though it is a hardy crop, growers are experiencing the problem of heavy premature fruit drop, incidence of nutritional disorders which leads to reduced yield and reduced quality which is accompanied with deficiency of nutrients, particularly micronutrients. Hence, to overcome the issue, the present study was conducted and the results revealed that the foliar spray of micronutrient combination of 0.5 % $ZnSO_4$ + 0.5 % $FeSO_4$ + 0.25 % Borax significantly increased overall growth of plants including plant height (0.86 m), spread in both East-West (0.90 m) and North- South (0.92 m) directions, reduced the incidence of fruit drop (45.60 % as against 79.63 % in control) resulting in increased fruit set (53.73 % as against 21% in control). The said combination of micronutrients was also associated with increased fruit physical parameters like increased fruit weight (43.69 g), pulp weight (43.03 g), fruit:pulp ratio (22.18) and higher yield levels (24.96 kg/plant).

Key words- deficiency, foliar spray, fruit drop

FARMER DISTRESS AND IMMEDIATE RELIEF FOR AGRICULTURAL DEVELOPMENT**ABHILASH SINGH MAURYA AND JOGINDER SINGH MALIK**

Department of Extension Education, CCS Haryana Agricultural University, Hisar-125004, Haryana (India)

Natural disasters such as droughts, floods, cyclones, storms, landslides and earthquakes can lead to extreme distress and hardship among farmers who predominantly lead subsistence existence. In these situations, they need at least a minimal amount of relief at rapid pace. In the past, crop insurance has been the vehicle for such relief but crop insurance typically covers only those farmers who have outstanding loans from banks. This leaves out marginal farmers who are unable to borrow from the banks. It also leaves out landless workers who depend on agricultural employment but are themselves not farmers. Therefore, a mechanism is required to bring quick relief to all those impacted directly or indirectly by natural disaster. Given that much of the cost of insurance is borne by the government, it is effectively a transfer rather than genuine commercial program. Therefore, it may be best to conduct the relief transparently as an emergency social program. The government should create a database that identifies farmers and landless workers with their respective Aadhar seeded bank accounts. In case of a natural disaster, transparently identified by weather data and a set of weather related criteria, the government should then transfer a minimum specified sum of cash immediately into these accounts. The cash would provide instant relief to those damaged by the natural calamity. For richer farmers who may want insurance above this relief, a separate commercially viable crop insurance program may be operated. If the government has a preference for an insurance program for this purpose, it should evolve a mechanism for the introduction of a diversified set of crop insurance products offered by different insurers who compete against one another. The objective should be to cover all farmers small, marginal and others with those having 2 ha or less land covered at substantial subsidy on the premium. Farmers with more than 2 ha land should be required to pay the premium in full to avail the benefits. Appropriate avenues should also be explored to create jobs for those farmers interested in exiting farming. Farm-oriented processing and small-scale industries offer two such avenues.

Key words: Natural disasters, Crop insurance

"EFFECT OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH, YIELD AND QUALITY OF CABBAGE (BRASSICA OLERACEA VAR. CAPITATA L.)."**ABHILASH SINGH, D. K. SINGH AND ASHISH K. SINGH**

Department Of Horticulture, Udai Pratap College, Bhojpur, Varanasi -221002 (U.P.) India

The experiment was conducted at research farm, Department of Horticulture, Udai Pratap College, Varanasi (U.P.) during the year 2016-17. The Nine treatments are T_1 -Recommended dose of NPK ha^{-1} (150 kg:125 kg:100 kg), T_2 - Half dose of NPK ha^{-1} + FYM @ 15 t ha^{-1} , T_3 - Half dose of NPK ha^{-1} + FYM @ 15 t ha^{-1} + *Azospirillum* @ 5 kg ha^{-1} , T_4 - Half dose of NPK ha^{-1} + FYM @ 15 t ha^{-1} + Phosphorus Solubilizing *Mycorrhiza* @ 5 kg ha^{-1} , T_5 - Half dose of NPK ha^{-1} + FYM @ 15 t ha^{-1} + Phosphorus Solubilizing *Mycorrhiza* @ 5 kg ha^{-1} + *Azospirillum* @ 5 kg ha^{-1} , T_6 - Half dose of NPK ha^{-1} + Vermicompost @ 2.5 t ha^{-1} , T_7 - Half dose of NPK ha^{-1} + Vermicompost @ 2.5 t ha^{-1} +

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Azospirillum @ 5 kg ha⁻¹, T₈-Half dose of NPK ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹ + Phosphorous Solubilizing *Mycorrhiza* @ 5 kg ha⁻¹ and T₉-Half dose of NPK ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹ + *Azospirillum* @ 5kg ha⁻¹ + Phosphorus Solubilizing *Mycorrhiza* @ 5 kg ha⁻¹ were evaluated in randomized block design with three replications.

The experimental findings was revealed that the treatment T₈ (Half dose of NPK ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹ + Phosphorous Solubilizing *Mycorrhiza* @ 5 kg ha⁻¹) showed better response to plant growth and its attributes on quality of cabbage (TSS and Ascorbic acid). Therefore, treatment T₈ can be used further in growth enhancement of cabbage.

A VIEW ON SITE-SPECIFIC NUTRIENT MANAEMENT IN RICE

ABHILASHA PATHAK, PRASHANT DEO SINGH, GOUTHU NAGA PANCHAVATHI, PRAMOD KUMAR¹

Department of Soil Science & Agricultural Chemistry, SVP University of Agri. & Tech. Modipuram, Meerut, U.P., Department of Agronomy¹, C.S. Azad University of Agri. & Tech, Kanpur, U.P.

Site-specific nutrient management (SSNM) is a plant-based approach for managing the nutrient requirements of rice. It provides principles and tools for supplying rice with nutrients as and when needed to achieve high yields while optimizing use of nutrients from indigenous sources. Three steps in SSNM are to establish a grain yield target, effectively use existing nutrients and apply fertilizer to fill the deficit between crop needs and indigenous supply. SSNM could decrease N rate to a greater extent without any sacrifice in grain yield, when compared with farmers' fertilizer practice. Number of productive panicles under SSNM but productive tiller rate was much higher under SSNM. Leaf area index LAI and root weight were lower under SSNM than those under Farmer field practices before panicle initiation, but the results were reversed after heading stage. SSNM increased efficient and high efficient LAI rates at the heading stage, dry matter accumulation from heading to maturity stage, ratio of root to shoot, photosynthetic rate in flag leaves after heading stage and light transmission rate in rice population at the full heading stage. Reasons for yield increase and nutrient uptake laws in rice under SSNM were that SSNM significantly reduced nitrogen applied rate without any sacrifice in grain yield. When compared with farmers' fertilizer practice, SSNM increased milling quality and transparency, whereas decreased chalky grain rate, chalky area and chalkiness, leading to an improvement in appearance quality. SSNM also decreased amylose content, gelatinization temperature and protein content, but increased gel consistency. This approach advocates optimal use of indigenous nutrients originating from soil, plant residues, manures, and irrigation water. Fertilizers are then applied in a timely fashion to overcome the deficit in nutrients between the total demand by rice to achieve a yield target and the supply from indigenous sources.

Keywords : Site specific nutrient management, nitrogen mangement, paddy rice system

“POPULATION DYNAMICS OF RICE INSECT-PESTS AND MANAGEMENT OF YELLOW STEM BORER (*SCIRPOPHAGAINCERTULAS WALKER*)”

ABHINANDAN YADAV AND P. K. GUPTA

Department of Entomology N.D. University of Agriculture & Technology, Narendra Nagar, (Kumarganj), Faizabad, 224 229 (U.P.)

The present investigations were carried out at NDU&T Crop Research Station of Masodha, Faizabad during *Kharif* 2015, with objectives to study population dynamics of insect-pests of rice, to study correlation between population of insect-pests of rice and abiotic factors and evaluation of newer insecticides against rice yellow stem borer. Population dynamics of insect-pests at different stages *viz.*, maximum tillering, panicle initiation, flowering and dough stages of crop. The Green Leaf Hopper, Leaf Folder, Yellow Stem Borer, Grass Hopper, and Rice Hispa were the prevailed insect pests of rice. The incidences of insect-pests were found maximum at tillering stage of crop and lowest at initial crop growth stage except Rice Hispa. The correlation coefficient between population of insect-pests and abiotic factors revealed that Yellow Stem Borer, Grass Hopper, and Leaf Folder population was negatively correlated with minimum temperature, relative humidity and rainfall. The population of Rice Hispa and Green Leaf Hoper was positively correlated with abiotic factors. Among the various insecticides evaluated against yellow stem borer, fipronil 5 SC @ 50 gm a.i./ha treated plots showed lowest infestation and gave higher grain yield (32.90q/ha) followed by imidacloprid 17.8 SC (31.90q/ha) and carbofuran 3 G (30.25q/ha). The highest cost: benefit ratio was also obtained from fipronil 5 SC followed by imidacloprid 17.8 SC and monocrotophos 36 SL which were economical than others.

Key word- Population dynamics, Rice, Abiotic factors and cost: benefit ratio.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

PLANT GROWTH REGULATORS (PGR) IN NURSERY**ABHINAV KUMAR, ATUL YADAV, DHEERAJ YADAV, SNEHA SINGH, SACHI GUPTA, RAVI PRATAP SINGH, HARENDRA AND ARCHIT SINGH***Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad*

Plant growth regulators are the chemical compounds other than nutrients which are required in small or minute quantities to regulate modify or inhibit the plant physiological processes. Plant growth hormones are the chemical compounds synthesized by the plant inside its body and transported from site of production to site of action to regulate, modify or inhibit the plant physiological processes. Gibberellins: Play important role in cell elongation in plant cells e.g., Gibberellic Acid GA1, GA3, GA7, Auxines: Play important role in cell division and cell multiplication. These substances are used mainly for the root initiation, e.g., Indol Acetic Acid (IAA), Indol Butaric Acid (IBA) and Naphthalic Acetic Acid (NAA), Cytokinins: Play important role in cell elongation, e.g., Kinetin, Zeatin, Absciscic Acid: Growth retarding substance and plays an important role in fruit drop and thinning, e.g., ABA, Ethylene: Mainly called as ripening hormone which hastens ripening in fruit crops. Ethrel also useful for sex expression in cucurbitaceous vegetable crops. Eg, Ethephon, Ethrel. Large number of plants are propagated by stem cutting, leaf cutting and layering. For promoting rooting, the commonly used hormone is IBA followed by NAA. IBA enhances root formation on cuttings. Cytokinins also help in quick and profuse root formation on cutting and layers. By use of IBA, profuse root formation is observed in cutting at fig, pomegranate, croton, rose rootstock, hibiscus, grape etc.

Keywords - Plant growth regulators, physiological processes, site of action etc

BONSAI STYLES, PLANTS, CONTAINERS, CULTURAL PRACTICES, SPECIAL PRACTICES, CARE AND MAINTENANCE**ABHINAV KUMAR¹ AND A.K.SINGH²***Department of Floriculture and Landscaping¹, Department of Fruit Science², N.D.U.A. & T. Kumarganj, Faizabad, U.P., India*

The word Bonsai is derived from Chinese Penjing and in Japanese 'bon' means, 'shallow pot' and the 'sai' means "plant" which is translated as 'tray planting'. Bonsai is the art of growing trees, proportionately in small containers, occasionally in combination with rocks of many forms, by treating them with certain techniques in order to reproduce in miniature the lordly appearance of large and aged trees or landscape as found in nature. In recent days, the demand for bonsais is growing rapidly in leaps and bounds and has attained the status of an exclusive sector in the landscape gardening industry. *Ficus benjamina*, *Ficus neriifolia*, *Schefflera arboricola*, *Crassula ovate*, *Portulacaria afra*, *Dracaena marginata*, It takes long time, in the first place growing a house plant and then successfully shaping into perfect bonsai. This system is highly practical and commonly used. It is carried out by taking cutting from the matured shoots, layering, grafting and budding methods. Seedlings of mature trees of local origin viz., gardens, terraces and fields along side of roads. For collection of these seedlings soil from the plants must be loosened using shovel, then only gently lift the plants without injuring the taproot. If the seedlings are to be planted immediately, simply cover the roots with loose and wet soil to prevent drying. If the planting delayed for few days, then cover the seedling with moist sphagnum moss or newspaper to keep the plants from drying out. After collection 2-3 year old seedling from the field, immerse the roots in a bucket of water or emulsion of clay and water.

Keyword Bonsai, small containers, demand, trees or landscape etc.

MODERN ASPECTS OF MUSHROOM CULTURE**ABHIRAM***Maya Group Of Colleges*

The production and culture of new species of mushrooms is increasing. The breeding of new strains has significantly improved, allowing the use of strains with high yield and resistant to diseases, increasing productivity and diminishing to use of chemicals for pest control. The improvement and development of modern technologies, such as computerized control, automated mushroom harvesting, preparation of compost, production of mushrooms in non composted substrate, and new methods of substrate sterilization and spawn preparation, will increase the productivity of mushroom culture. All these aspects are crucial for the production of mushrooms with better flavor, appearance, texture, nutritional qualities and medicinal properties at low cost. Mushroom culture is a biotechnological process that recycles ligninocellulosic wastes, since mushrooms are food for human consumption and the spent substrate can be used in different ways. Discover the world's

Modern aspects of mushroom culture.

USE OF AGRO-INDUSTRIAL WASTE IN CROP PRODUCTION**ABHISHEK ANEJA¹, AMAN DEEPRANGA², SOURAV KUMAR²***Department of Agronomy, ²Department of Genetics and Plant Breeding, School of Agriculture, Lovely Professional University, Phagwara-144411*

In India, about 960 million tonnes of solid waste is being generated annually as by-products during industrial, mining, municipal, agricultural and other processes. 350 million tonnes are organic wastes from agricultural sources. Agro-industrial waste is the waste generated by the agro-industrial activity which involves any material that is rendered purposeless during a production process such as that of factories, industries and mills. Most of the agro-industrial wastes are untreated and underutilized and are disposed of either by burning, dumping or unplanned landfilling. Due to high nutritional composition, these residues are not labelled as “wastes” but considered as raw materials for other product formation and developments. The existence of such nutrients in these residues offers suitable conditions for the prolific growth of microorganisms. These microorganisms have potential to reuse the waste as raw materials for their growth through fermentation processes. These raw materials consist of molasses, husks, bagasse, seeds, leaves, stem, straw, stalk, shell, pulp, stubble, peel, roots, etc. and used for animal feed, soil improvement, fertilizers, manufacturing, and various other procedures. Agricultural residues are rich in bioactive compounds and are also free from phytotoxic compounds as evident from the phytotoxicity test. The organic substrates in solid waste can be biodegraded and stabilized by composting and the final compost products could be applied to land as the fertilizer or soil conditioner. Most of the field wastes can be used globally for the production of biofuels, biogas in place of heat, and power through various technologies.

Keywords: Untreated, Underutilized, Bioactive, Phytotoxicity Test

SHIITAKE MUSHROOM: A NEW HOPE FOR MUSHROOM CULTIVATION**ABHISHEK PANDEY***Department of Genetics and Plant Breeding, Chaudhary Charan Singh University, Meerut-250001*

The Shiitake mushroom is used as anticarcinogenic, anti-inflammatory, antioxidant, antifungal, antibacterial, antiviral as well as antithrombotic in cardiovascular disorders. This article has been written to throw some light on Shiitake mushroom which has many nutritional values. In (15 gram) Niacin 11% of the RDI, vitamin B5 33% of the RDI, selenium 10% of the RDI, vitamin B6 7% of the RDI, Lentinan (1,3 beta D glucan). Cultivation practices for this mushroom where recently done with willow tree it is nearly calculated that average 750 gm of mushroom from 1 kg of willow sawdust this mushroom has a good self life and dried shiitake fetching Rs.2000/kg. This mushroom is grown with very low economic investment with high return. A successful story related to Shiitake, has further refined the growing technology by using willow wood as a substrate. He is the first farmer in the country to use willow tree wood as a substrate to grow Shiitake variety. It was found that growing Shiitake on sawdust but return was not so good production later on some scanty reference in literature about using willow tree logs as a medium for growing. Some reports are found in favor of high return with an investment of just Rs. 6,000 some years back today it is estimated worth nearly Rs. 4 crores all earned from mushroom cultivation. Explaining the procedure the entrepreneur says, “willow logs of 40 inch length and three to four inch diameter are ideal. Holes are drilled into the logs and spawns (in the form of bullets) are inserted into the holes and sealed with wax. The logs are kept in the open under shade. Fruiting of shiitake starts in just three months and continues for four to five years. Basically shiitake is boon for the medical field in relation with cancer treatment & depression patient.

MUSHROOM CULTIVATION BY WASTAE**ABHISHEK SHUKLA***Department of plant pathology, Chandra Shekhar Azad University Of Agriculture And Technology Kanpur 208002, UP, India*

Mushroom cultivation is an effective method for the production of nutritional food in addition to offering a holistic approach to agro waste management by utilization of the abundant lignocellulosic waste including sisal leaf decortication waste (SLDW). Production of 1 kg of mushrooms generates 5 kg of a co-product called spent mushroom substrate (SMS). Alternative means of disposal of the resulting SMS is production of extracellular enzymes generated by mushrooms during their growth and development. In this study, *Pleurotus HK 37* was studied for its ability to produce laccase manganese peroxidase (MnP), lignin peroxidase (LiP) and xylanase on SLDW under solid-state fermentation. Laccase activities reached the highest values of 27.3 U/ml when the substrate was fully colonised. The activity declined with each subsequent harvest to 15.0 U/ml. MnP assay had two peaks of 8.9 U/ml and 8.0 U/ml on full colonisation and during the 3rd flush, while LiP and xylanase activities had highest recorded activities of 0.34 U/ml and 0.28 U/ml, respectively. The results of this study demonstrate the potential utilization of sisal leaf decortication waste as raw materials for simultaneous production of edible mushrooms and extracellular enzymes from a commercial fungus, *Pleurotus HK 37*, which is a potential biotechnological application.

EFFICACY OF OIL CAKES EXTRACTS AGAINST LARVAL MORTALITY OF RICE ROOT KNOT NEMATODE (*MELOIDOGYNE GRAMINICOLA*).**ABHISHEK KUMAR, KAMAL KHILARI, JASKARAN SINGH, AMIT KUMAR YADAV, AJAY KUMAR MISHRA AND SATPAL SINGH***Department of Plant Pathology SVPUA&T Meerut 250110 (U.P.)*

Rice is one of the most important food crops in the world. In India, rice contributes 43 per cent of the total food grain production and 46 per cent of the total cereal production. Rice crop is affected by many fungal, bacterial, viral and nematode diseases. Among the nematodes, rice root knot nematode (*Meloidogyne graminicola*) is considered as a major problem in rainfed upland and low land rice. Root knot nematode produced different type symptoms on rice like stunted growth, leaf yellowing and wilting during the hottest part of the day. The main symptom produced by root-knot nematode was gall formation. Galls on rice roots were club and hooked shaped. In present study, the experiment was conducted to test the efficacy of oil cake extract against mortality of rice root knot nematode. In this experiment, eight oil cakes viz. Neem, cotton, linseed, groundnut, sunflower, sesamum, mustard and mahua oil cake were taken in three different @ 5, 10 and 25% concentration. The nematicidal activity of extract of oil cakes was also tested against J₂ of *Meloidogyn graminicola*. At 5% concentration, maximum larval mortality (89%) was observed in linseed cake extract after 48 hours of inoculation. After 72 hours of inoculation, 100% larval mortality was observed in all tested cake extract. At 10% concentration, after 48 hours of inoculation, maximum larval mortality (100%) was observed in linseed cake extract followed by neem cake extract (99.67%). At 25% concentration, all tested oil cake extract were effective against J₂ of *Meloidogyn graminicola* with 100% larval mortality within 24 hours of inoculation.

Key words:- *Meloidogyne graminicola*, Larval mortality, and oil cakes extract.

FARM MECHANIZATION & POST HARVEST TECHNOLOGIES AND THEIR MANAGEMENT**ABHITEJ SINGH SHEKHAWAT¹, AKANSHADEORA², PUSHPENDRA SINGH³ & BHAWANI SINGH PRAJAPAT⁴**

¹Department of Soil Science & Agricultural Chemistry, ²Department of Plant Pathology, ³Department of Horticulture & ⁴Department of Agronomy, Rajasthan College of Agriculture, MPUAT, Udaipur.

Agriculture Mechanization technology plays a key role in improving agricultural production in developing countries and should be considered as an essential input to agriculture. The term "Farm Mechanization" is used as an overall description of the application of the variety of tools, implements, equipment, machinery, power & other mechanical inputs. Empirical evidence confirms that there is a strong co-relation between Farm Mechanization and Agricultural Productivity. State with greater availability of farm power shows higher productivity as compare to others. The Govt. of India had launched Central Sector Scheme "Sub-Mission on Agricultural Mechanization (SMAM)" under the aegis of National Mission on Agricultural Extension & Technology in all states to promote the usage of farm mechanization and increase the ratio of farm power to cultivable unit area up to 2 kW/ha and the most ambitious scheme "Chief Minister Samagra Gramya Unnayan Yojana (CMSGUY)" with an objective to achieve the desired growth of Agricultural Mechanization by providing one Tractor Unit to each revenue village of the State covering 25 villages. Post harvest technologies deals in the operations required to make agricultural commodities edible after harvesting and to increase the usable economic life of the crops and commodities. By performing the operations, value addition is done to the commodities with subsequent benefits such as more profit to the producer / trader, avenues for entrepreneurs & employment generation, food security and socio-economic uplift. It is done through performing operations such as primary & secondary processing and by performing operations of preservations like canning, refrigeration, controlled atmospheric storage, dehydration or drying, chemical treatment and use of subatomic particles. The application of sustainable mechanization in post-production operations through more efficient use of labour, the timeliness of operations and more efficient field and off field operations contribute to high-productivity systems. Examples of the application of mechanization in post-production operations are threshing, dehulling and milling operations, drying, processing of roots and tubers, transportation, hire services, repair and maintenance.

STORAGE QUALITY OF POTATO TUBER MOTH (*PHTHORIMAEA OPERCULELLA*)**ABHIVIVEK* NAVEEN KUMAR** VINAY KUMAR KARDAM*****

Department of Entomology, YS Parmar UHF Nauni Solan (HP), Department of Plant Pathology, YS Parmar UHF Nauni Solan (HP),

****Department of Plant Pathology, SKRAU Bikaner (Raj.)*

Potato tuber moth (PTM), *Phthorimaea operculella*, is a serious pest in field and storage system, in most countries where potatoes are grown, where the use of repellent plants is an environmentally sound alternative to the application of chemical pesticides. Potato tuber moth is a highly destructive pest of the cultivated potato (*Solanum tuberosum* L.) in the tropics and subtropics and causes significant damage to both leaves and tubers. Entomopathogens offer promise as alternatives to broad spectrum insecticides for management of this

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

pest. Many cultural practices that are used by farmers to improve the yield and quality of potato can also limit the development of the potato tuber moth and minimize damage to tubers. Low infestation at harvest and rapid handling of the potatoes going into store established good initial storage conditions and decreased the likelihood of post-harvest losses. Potato tuber moth control was achieved by applying a synthetic pyrethroid (permethrin) or *Bacillus thuringiensis* at the beginning of the storage period.

Keywords: repellent, infestation etc.

STUDIES ON SEED MYCOFLORA OF *WITHANIA SOMNIFERA* (L.) DUNAL IN RELATION TO DIFFERENT STORAGE CONDITIONS AND THEIR EFFECT ON SEED GERMINATION AND SEEDLING VIGOUR

ADEEBAANWAR¹ & A. R. ANSARI²

¹M. B. Govt. P. G. College, Haldwani, Nainital, Uttarakhand, ²Govt. Degree College Gairsain, Chamoli, Uttarakhand, India

Withania somnifera (L.) (Ashwagandha) is an important medicinal plant belonging to the family Solanaceae. Present studies were carried out to investigate the fungi associate with seeds in relation to different storage conditions (Nature of containers, duration and temperature) and their effect on seeds germination and seedling vigour. The experiments were conducted at Deptt. Of Botany, MBPG College Haldwani, K.U. Nainital. The seeds were stored in three different containers i.e. gunny bags, polythene bags and tightly sealed steel containers at three different temperatures i.e. 20°C, 30°C & 40°C for the durations of 2, 4 & 6 months. A total 17 fungi were isolated from seeds kept in different storage conditions by using standard blotter paper method. Among three containers used in studies, the highest number of fungi was found to be associated with the seeds kept in gunny bags at all temperatures viz. 20°C, 30°C & 40°C and durations viz. 2, 4 & 6 months followed by polythene bags and tightly sealed steel containers. Similar results were also found when seeds were tested for percent germination and seedling vigour. The lowest percent germination and seedling vigour was recorded with the seeds kept in gunny bags at all durations of storage and temperatures used in experiment. The gunny bags were not found safe for storage of *W. somnifera* seeds in comparison to tightly sealed steel container and polythene bags. Seeds kept in gunny bags absorbed higher moisture as compared to other two containers. Thus the tightly sealed steel containers can be suggested as good container for storage of *W. somnifera* seeds at different temperatures for long durations of storage.

INCIDENCE OF CHICKPEA DISEASES UNDER NICRA VILLAGES

ADESH KUMAR, NISHI ROY AND ABHIJEET SRIVASTAVA

Krishi Vigyan Kendra, Bharari Jhansi-284003

India is the largest producer of pulses in the world with 24% share in the global production. The major pulse crops, viz. chickpea (*Cicer arietinum* L.), pigeonpea [*Cajanus cajan* (L.) Millsp.], mungbean [*Vigna mungo* (L.) Hepper.], urdbean [*Vigna radiata* (L.) R, Wilczek], lentil (*Lens culinaris* Medikus) and field pea (*Pisum sativum* L.) of India. Chickpea contributes the single largest share in India's export basket of pulses registering 85.64% and 84.87% share in the total pulses export during 2014-15 and 2015-16 respectively. Nearly 172 pathogens have been reported so far that infect chickpea (*Cicer arietinum* L.) in different parts of the world, but only a few of them have the potential to devastate the crop. Some diseases are persistent problems in chickpea production in wide geographical areas, notably, ascochyta blight, fusarium wilt, dry root rot, stunt [caused by bean (pea) leaf roll virus], botrytis gray mold, collar rot, black root rot, phytophthora root rot, and pythium root and seed rot, while others are sporadic in occurrence or endemic indistribution. In this study, NICRA villages (Gandhinagar and Birgua come to Block Badagaon, Jhansi) were survey during Rabi 2017. It was observed that two disease namely Fusarium wilt (*Fusarium oxysporum* f. sp. *ciceri*) and Dry root rot (*Rhizoctonia bataticola*) reported in the farmer's field with different disease incidence. It was revealed that the maximum disease incidence (20% and 18%) was found Fusarium wilt and Dry root rot respectively. Ascochyta blight disease and Botrytis gray mold are usually not seen in the field. The field symptoms of wilt are dead seedlings or adult plants, usually in patches. The disease can affect the crop at any stage.

BREEDING CLIMATE-SMART PULSE VARIETIES

ADITI ELIZA TIRKEY*, GIRISH TANTUWAY, ALOK KUMAR SINGH

Department of Genetics and Plant Breeding, Institute Of Agricultural Sciences, Banaras Hindu University, Varanasi-221005

Food legumes also play an important role in low-input agriculture by reducing the dependence on nitrogen fertilizers. India ranks first in the pulse production in the world but lags behind in productivity because of constraints like decline in area, low genetic yield potential, climate change, poor seed replacement and post-harvest losses. Climate change has major impact on the pulse production since various abiotic and biotic stress factors which are influenced by climate change directly or indirectly which ultimately affects the yield. In order to achieve high productivity, adaptability and sustainability of pulse crops breeding climate-smart varieties appears to be most practical and economical approach for managing stresses in this era of changing climatic conditions. Breeding for resistance to various abiotic and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

biotic stresses we need to have the knowledge about the effect of various stress, resistance mechanism, and sources of resistance, breeding methods, selection environment, selection criteria and screening techniques for selection of elite genotypes. For obtaining better results there should be improvement in screening techniques, use of molecular markers for identifying and utilizing economically important genes, use of in vitro culture for transferring desirable genes from wild to cultivated species, use of genetic engineering using alien genes which offer opportunities for improving stress resistance in future cultivars of food legumes. The relative importance of various stress factors differs not only from crop to crop but also from region to region for same crop, therefore it is challenging since several stresses occur together requiring multiple stress resistance. Conventional breeding approaches show success but effectiveness can be improved by application of suitable biotechnological tools.

Keywords: Legumes, Climate Change

EFFECT OF DIFFERENT LEVEL OF PHOSPHORUS ON CHICKPEA AND THEIR SPACING.

ADITYARAJ INANIYA and POONAM PANDURANG SHETE

Department of Agronomy, School of Agriculture, Lovely Professional University, Phagwara, 144411 Punjab, India, Assistant Professor, Department of Agronomy, Lovely Professional University, Phagwara, 144411, Punjab, India

A field experiment was carried out to study the effect of different spacing and levels of phosphorus on growth and yield of desi gram (*Cicer aeritimum*) variety PBG-5 at the Crop Research Farm of Lovely Professional University of agriculture and technology and sciences, Phagwara, during winter season in 2017. The results revealed that different Spacing (20cm, 30cm, and 40cm) and phosphorus levels (25 kg ha⁻¹, 40 kg ha⁻¹, 55 kg ha⁻¹, and 70 kg ha⁻¹) significantly affected plant height, no. of root nodules and number of pods per plant. The maximum plant height (28.22 cm) was recorded from treatment no. 8 (55 kg P ha⁻¹ and 30 cm spacing) at 60 DAS. Similarly, higher number of root nodules (23.62) per plant was recorded from the treatment no. 12 (40 cm spacing and 70 kg Phosphorus ha⁻¹) at 60 DAS. The maximum number of pods per plant (24.33) was observed from the treatment no. 8 (55 kg P ha⁻¹ and 30 cm spacing). Generally the results revealed that treatment no. 8 (55 kg P ha⁻¹ and 30 cm spacing) gave better performance in approx all the parameters studied.

KEYWORDS : Crop ; Chickpea; Variety ; Treatment; Fertilizer.

MULCHING IN VEGETABLE CROPS

ADITYARANJAN, MANISH KUMAR AND BIPUL KUMAR SINGH

Deptt. of Horticulture (Vegetable & Floriculture.), Bihar Agricultural College, Sabour, Bhagalpur (Bihar), 813210.

Mulching technical term means 'covering of soil'. Mulching in general is a beneficial practice for crop production. It is the practice of covering the soil or ground and enabling it favourable conditions for plant growth, development and optimum crop production. It prevents the direct evaporation of moisture from the soil and thus limits the water losses and conserves moisture. Mulch facilitates fertilizer placement and reduce the loss of plant nutrient through leaching, can improve soil biology and also provide a barrier to soil pathogens. It maintains warm temperature at night time, relatively cooler temperature at day; which enhances rapid seed germination, prevent weed growth in crop land area and helps in quick establishment of a strong root growth system which favours healthy growth of young plant seedlings as well as develop a microclimate underside of the sheet, which is higher in carbon-di-oxide due to the higher level of microbial activity. Mulching techniques for vegetable production such as very thin film is used for short duration crops and round holes are made at the centre of the film using a punch or a bigger diameter pipe and a hammer or a heated pipe end could be used. Prepare the soil well and apply the required quantity of FYM and fertilizer before mulching. Mulch film is then inserted (4-6") into the soil on all sides to keep it intact. Seeds are sown directly through the holes made on the mulch film. In transplanted crops, the seedlings are planted directly into the hole. Mulches of indigenous origin which are readily available on farm land (paddy straw, dry leaves, compost mixes etc.) and in turn, reduces the cost of cultivation and conserves the optimum moisture for efficient crop production.

GREEN SYNTHESIS OF SILVER NANOPARTICLES AND ITS EFFECT ON SEED GERMINATION AND SEEDLING GROWTH IN VIGNA MUNGO

Aiman Zafar, Irshad Mahmood and Rose Rizvi, Department of Botany, Aligarh Muslim University, Aligarh, India

Nanotechnology is emerging as new subject of research in various fields including agriculture. Keeping this in mind experiment was carried out to study the effect of green synthesised nanoparticles from leaf extract of Castor. The synthesised nanoparticles were characterised by UV-Vis spectroscopy and particle shape and size by SEM and EDX. The results showed that the seeds treated with silver nanoparticles improved both germination index and seedling growth of *Vigna mungo*. Thus, nanotreated seeds can be used in agriculture to increase the production and improve plant health for better yield.

Keywords: Castor, Green Synthesis, Plant growth, seed germination, *Vigna mungo*.

SEED LEGISLATION IN INDIA

AJAY CHAUHAN¹ AND AKHILESH SHARMA

Department of Vegetable Science, CCS Haryana Agricultural University, Hisar

Seed is a key component among all inputs for sustainable crop production. It is estimated that quality of seed accounts for 20-25% of productivity. The response of all other inputs depends on quality of seeds to a large extent. The need for a good viable seed for prosperity of human race is mentioned in Rigveda of ancient India. It is mentioned in the primeval manusmriti as "Subeejam Sukshetre Jayate Sampadyate" which literally means "A good seed in a good field will win and prosper". It is very much essential to maintain its purity and quality through various stages of seed production i.e. Breeder, foundation, registered and certified seed. Government of India besides had framed and brought out different legislations to protect the quality of seeds and planting materials. The rapid development of agricultural production necessitated the enactment of seed legislation. Need to maintain quality in terms of genetic and physical purity is realized for first time in 1963 with the establishment of National Seeds Corporation (NSC). The Seeds Act was formulated in 1963 and has come into force in 1966. On 29th December 1966, the Seeds Act was passed followed by Seed rules, 1968. It came into force throughout the country on 2nd October 1969. India is still importing the vegetable seeds from other countries major being radish followed by cabbage and pea. Therefore, The Seed Act, Seed Rules, Seed (control) order, National Seed Policy, Plant quarantine order, PPV & FR Act to not only to protect breeders, researchers but also a common farmer. These legislations have taken care of the quality of the seeds at production, processing and marketing levels to ensure that the farmer get the best quality seed. Therefore it is necessary that the information regarding seed legislations must reach to farmers also to make them aware of their rights.

IMPACT OF LAND CONFIGURATIONS, IRRIGATION SCHEDULING AND WEED MANAGEMENT ON YIELD AND ECONOMICS OF CHICKPEA (*CICERARIETINUM* L.)

CHOURASIYAAJAY*, NAIK K.R., CHAUHAN ABHISHEK AND DAS SHIVNATH

Department of Agronomy, Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur- 482004 (M.P.)

The field experiment was conducted during Rabi 2013-14 at Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur to study the impact of land configurations, irrigation scheduling and weed management on yield and economics of chickpea. The treatments comprised three land configurations (Flat bed, Broad bed furrow, Ridge-furrow); three irrigation schedules (Irrigation at branching, Irrigation at pod development, Irrigation at branching and pod development) as main plot treatments and three weed management (Weedy Check, Hand weeding twice at 25 and 50 DAS, Pendimethalin @ 1.0 kg ha⁻¹ as pre emergence) as sub-plot treatments. These treatments were tested in split plot design with three replications. Ridge-furrow method resulted in significantly higher seed yield (1512.33 kg ha⁻¹), gross monetary returns (₹74794 ha⁻¹), net monetary returns (₹43991 ha⁻¹) and benefit: cost ratio (2.40) over flatbed and broad bed furrow. Irrigation at branching and pod development gave appreciably higher seed yield of 1483.33 kg ha⁻¹, gross monetary returns (₹73366 ha⁻¹), net monetary returns (₹42089 ha⁻¹) and benefit: cost ratio (2.31) over rest of the irrigation scheduling. Application of Pendimethalin @ 1.0 kg ha⁻¹ PE resulted in 52.17 per cent more seed yield (1592.74 kg ha⁻¹), gross monetary returns (₹79225 ha⁻¹), net monetary returns (₹49504 ha⁻¹) and benefit: cost ratio (2.66) over weedy check. However, hand weeding twice registered in significantly higher seed yield 1719.56 kg ha⁻¹ and gross monetary returns (₹84998 ha⁻¹) but had lower B: C ratio.

FORECASTING WHEAT YIELD USING TIME SERIES MODELLING IN HARYANA

AJAY KUMAR¹*, URMIL VERMA¹ AND ANIL²

¹Department of Mathematics and Statistics, College of Basic Sciences and Humanities, CCS Haryana Agricultural University, Hisar-125004, ²Department of Statistics, Central University of Haryana, Mahendergarh-123031

India is an agrarian country in which Agriculture is the single most important contributor to the Indian economy because of its significance in food security, trade and industry. Wheat is the most important food grains of human in India. Wheat crop is India's prime most staple harvest, placed after Rice. It is mostly consumed in the north and north-west parts of the country. At the time of independence in 1947, production and productivity of wheat were quite low at 6.46 million tones and 663 kg/hectare respectively. At present, India is the second largest producer of wheat in world after China. The purpose of this study was to fit a model that forecast the production of wheat in Haryana by using annual time series data from 1970 to 2014. Random walk, random walk with drift, linear trend, moving average, simple exponential smoothing, Brown's linear exponential smoothing, Holt's linear exponential smoothing and ARIMA models were employed and compared for finding out a best model to forecast the yield of wheat in Haryana. The best fitted model was selected based on performance in goodness of fit criterion; Akaike Information Criterion (AIC) and Schwarz's Bayesian information criterion (SBIC). This study found that on the basis of AIC and SBIC, linear trend = 623.247 + 4.47523t and Simple exponential smoothing with alpha = 0.2093 respectively be the best model to forecast wheat yield in Haryana. The forecast value by using AIC was obtained as

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

851.484 million tones in 2020 and 878.336 million tones in 2026. Further by using SBIC, the forecasting value obtained as 793.433 million tones in 2026.

Keywords: ARIMA; Time Series Models; Forecast; Wheat yield; Exponential smoothing.

EFFECT OF DIFFERENT MEDIA ON MYCELIAL GROWTH OF THREE *PLEUROTUS* SPP. (*PLEUROTUS FLORIDA*, *P. FLABELLATUS* AND *P. SAPIDUS*)

AJAY KUMAR MISHRA, GOPAL SINGH, SATPAL SINGH, AMIT KUMAR YADAV, ABHISHEK KUMAR

Department of Plant Pathology, SVPUA&T, Meerut, UP, India.

The cultivation and various uses of mushroom have been reported from ancient time in several literatures including Vedas. The present investigations were carried out on oyster mushroom, in which three strains of *Pleurotus* spp. were used for variability in colony characters. For this purpose six different media, Barley Extract Agar, Oat Extract Agar, Wheat Straw Extract Agar, Wheat Extract Agar, Malt Extract Agar and Potato Extract Agar were used. Among the evaluation of six media, maximum radial growth in *Pleurotus florida* was observed in Barley extract agar medium and oat extract agar medium (89.50 mm). While minimum radial growth was observed on PDA (61.25 mm). In case of *P. flabellatus* maximum growth rate was observed in Barley extract agar medium (81.50 mm) while minimum growth rate was observed on PDA (50.50 mm) and In case of *Pleurotus sapidus* maximum growth rate was observed in Barley extract agar medium and oat extract agar medium (90.00 mm), while minimum growth rate was noticed on malt extract agar medium (63.50 mm). This Study Concludes that Barley extract agar medium and oat extract agar medium are the best media for radial growth of *Pleurotus florida*, and *Pleurotus sapidus*, while in case of *Pleurotus flabellatus* barley extract agar medium is the best media for radial growth.

NEMATODES AS CONSTRAINTS TO AGRICULTURAL FOOD PRODUCTION

AJAY SINGH SINDHU* AND R.S. KANWAR**

Indian Agricultural Research Institute, New Delhi, Chaudhary Charan Singh Haryana Agricultural University, Hisar

One of the most important objectives of the Millennium Development Goals is to eradicate extreme poverty and hunger. Sufficient nourishment for the whole population of the world is one of the challenges of the present era. According to an estimate plant parasitic nematodes are causing much more damage annually compared to insect pests. A crop yield loss due to these tiny unseen pests in various countries is enormous. They caused projected yield loss of 12.3 % (\$157 billion dollars) worldwide. Out of which \$40.3 million is reported from India. Farmers/growers identified insect pests, and other constraints as production problems but overlooked plant parasitic nematodes. Nematode diseases are difficult to control because of their hidden nature and hence, more often overlooked. Plant parasitic nematodes not only cause damage individually but form disease-complexes with other micro-organism and increased the crop loss. Also the symptoms of nematode damage are not specific, resemble with the symptoms of other pathogens and abiotic stresses such as water and mineral deficiency. Future agricultural growth must come from productivity growth to address the persistent problems of poverty, food insecurity and malnutrition. Recommended measures against nematode diseases include use of clean nematode free planting material, resistant varieties, and crop rotations to suppress nematode infestation. Integrated nematode management can be promoted through farmers-nematologists interactions, local production of bio-control agents and strict chemical pesticide regulations. Farmer's/grower's awareness and skills are equally important in minimizing nematode infestation and yield losses, to sustain the agriculture production.

Keywords: Plant parasitic nematodes, yield losses, Integrated nematode management etc.

EFFECT OF LOW COST MEDIA IN MICROPROPAGATION ON BANANA

AJAY YADAV, MANOJ KUMAR, AMIT KUMAR AND MANOJ KUMAR

Department of Horticulture, Sardar Vallabhbhai Patel University of Agriculture And Technology, Modipuram, Meerut (U.P.) India 250110

Tissue culturing has become a routine method for propagating plants in high technology laboratories. Bananas (*Musa* spp.) are important staple crop in tropical and sub-tropical countries providing a good source of carbohydrates, minerals and vitamins. The low cost alternative components of tissue culture media were evaluated for their potential to supply nutrients and to support growing explant of Banana cultivar *in vitro* for their cost effectiveness against conventional high cost media. Micropropagated plants are increasingly becoming the planting material of choice, but the higher costs of plantlets have prevented the growers from benefiting from tissue culture technology. Agar is the most commonly used gelling agent for preparation of media, which adds significantly to the cost of media. The use of cheaper alternative to agar eliminates the need of agar. Therefore, the efficacies of sago, isabgol, asparagus of tapioca, and corn

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

flour, as a gelling agents have been tested to reduce the cost of plantlets. The performance of low cost gelling agent's sago and tapioca starch were found to be best and could compare well with that of agar. The results showed the potential of the cheaper substitutes for economic commercial tissue culture production of banana cv. 'Udhayam' replacing the costliest gelling agent agar.

Keywords: Banana, low cost media, agar, micropropagation.

ADVANCES IN DAIRY TECHNOLOGY

AJAYKUMAR GOUR¹, BADAMA HESWARAREDDY², PINGIDI SOUJANYA³, THOTA ANITHA⁴

^{1,2,3,4} *Department of Agriculture, Bhagwant University, ajmer, rajasthan, (India) 305004*

Many of milk's functional molecules could not be discovered until the right concordance of novel separation and analytical technologies were developed and applied. Many health-promoting components still await discovery due to technical challenges in their identification, isolation and testing. As new analytical technologies are assembled, new functional milk molecules will be discovered. Bovine milk is a source of a wide array of known bioactive compounds from a variety of molecular classes, including free glycans, lipids, peptides, proteins, glycoproteins, stem cells and microRNA. Because milk is such a complex mixture, when analyzed without fractionation or purification, many components mask the analytical signal of others, so some components cannot be detected. Modern analytics allow for the discovery and characterization of hundreds of novel milk compounds with high-resolution and high accuracy. Liquid chromatography paired with electrospray ionization allows the separation of peptides, glycans and glycolipids for improved mass spectrometric detection. Target proteins and glycoproteins can now be purified from intact milk or other dairy streams by chromatography in order to better characterize these proteins for new bioactivities. The combination of advanced analytics with the new engineering capabilities will allow for high molecular resolution and separation techniques that can be scaled-up to semi-industrial and industrial scale for translation of lab-based discoveries. Bioguided analysis and design of dairy processing side streams will result in the transformation of waste into isolated functional ingredients to add value to dietary products.

Key words :-proteins, microRNA, purification, processing, Bovine milk.

ANALYSIS OF GENETIC DIVERSITY OF INDIAN MELON (*Cucumis melo* L.) LAND RACES AND ITS COMPARISON WITH GLOBAL REFERENCE MELON POPULATIONS

AJAZ AHMED MALIK

Division of vegetable science SKUAST-K

The investigation entitled, "Analysis of genetic diversity of Indian melon (*Cucumis melo* L.) land races and its comparison with global reference melon populations" was conducted at Department of Vegetable Science and School of Agricultural Biotechnology, Punjab Agricultural University Ludhiana. Eighty-eight melon accessions collected from Uttarakhand and Uttar Pradesh states of India representing four agroecological regions (six sub-regions) and eight reference accessions from USA were characterized and evaluated for nineteen morphological traits of plant and fruit, biochemical traits such as TSS, ascorbic acid content, titrable acidity and dry matter content, SSR genotyping and reaction to diseases. Significant differences were noted among all the accessions for all the characters observed. Phenotypic and genotypic coefficients of variation were found to be high for fruit weight and node at which first hermaphrodite flower appears. High heritability along with high genetic advance was recorded for fruit weight, node at which first hermaphrodite flower appears, fruit length, seed cavity length, number of primary branches per vine and total soluble solids content. D2 analysis grouped the accessions into ten clusters. The reference accessions obtained from USA and land races collected from different agro-ecological zones of India were found to be scattered in different clusters. No parallelism was found between genetic and geographic diversity. DNA polymorphism was utilized to cluster the genotypes into different clusters based on similarity as well as dissimilarity coefficients. On basis of SSR analysis, dendrogram clustered 96 accessions into three major groups. There was a significant correlation between botanical groups and the clustering pattern. Accessions belonging to *cantalupensis* cluster together in cluster I, accessions of *reticulatus* group cluster together in cluster II and *momordica* group cluster together in cluster III. However, some accessions of *cantalupensis* and *reticulatus* were intermixed in cluster I and II. Reference accessions cluster together forming a genetically unique assemblage in subgroup IIA and shared similarity coefficient of 0.65 with sub-group IIB. This suggested that reference accessions shared genetic affinities with Indian melon accessions which further established the fact that have been taken from India through trade route during ancient times, that could not have been predicted based on their geographic origin. Four accessions were free from CMV and two accessions exhibited immune reaction to downy mildew. The results inferred that these melon accessions could be used to broaden the genetic base of melon.

Keywords: CMV, downy mildew, genetic advance, heritability, melon, SSR

SOIL MICROBIAL DYNAMICS AS INFLUENCED BY SOIL MOISTURE CONDITIONS**AJEET KUMAR*, AMARJEET KUMAR AND RAMJEET YADAV***Department of Soil Science & Agricultural Chemistry, Bihar Agricultural University, Sabour, Bhagalpur, Bihar, India 813 210*

Soil moisture being a strong determinant of microbial activity, exerts dominant control over gaseous and liquid diffusion rates and at the same time affects oxygen and substrate availability. Increasing soil moisture reduces gaseous diffusion rates, directly affecting microbial physiological status and activities by limiting the supply of the dominant electron acceptors. As the matric potential in soil water decreases, cells must spend energy to attain osmotic equilibrium with the surrounding solution that reduces their growth and activity. Wetting and drying also affects microbial activity in soil, respiration rate, DHA and microbial community structure. Physiological drought induced by salinity induced osmotic stress results in poor plant growth and low soil microbial activity. The response to soil drying varies widely across organism functional types (e.g., soil fauna, bacteria, fungi) and species. Fungi are generally considered more tolerant than bacteria to soil drying. This is due to their ability to accumulate osmo-regulatory solutes that do not impair metabolism and to their filamentous structure, which allows them to reach and exploit substrates even at very low soil moisture levels, where diffusivity is low. The documented scientific literature converges towards the conclusions that soil moisture affects the microbial population, diversity and their biological and biochemical properties by affecting substrate availability, diffusion of liquids and gases and regulating the osmotic stress faced by soil micro-organisms. The functional relationships between water content or potential and the soil microbial demography appear to be hysterical in case of wetting drying cycles because usually the response time for the microbial characteristics to adapt to an altered soil moisture regime is far from instantaneous. Soil moisture conditions are inherently more dynamic than any other soil characteristic. Therefore, present study was focused on understanding of the microbial characteristics under dynamic moisture conditions together with the biochemical pathways of nutrient availability and transformations, organic matter decomposition and substrate availability that can be help in better manage of soil water and diverse soil microbial resources in agriculture.

Keywords: *Soil moisture, soil microorganisms population and activity*

UNRAVELING THE EFFECT OF FOLIAR FEEDING OF CARRAGEENAN OLIGOMERS ON GROWTH, PHYSIOLOGY, TRICHOMES AND ESSENTIAL OIL PRODUCTION IN PEPPERMINT (*MENTHA PIPERITA* L.)**AJMAT JAHAN¹*, M. MASROORA. KHAN¹, BILAL BHAT¹ AND ARSHIYAAKEEL¹***¹Plant Physiology Section, Department of Botany, Aligarh Muslim University, Aligarh, 202002, India*

Carrageenan, a marine polysaccharide, after depolymerization by Co-60 gamma rays has shown promising plant growth promotion and other biological activities. Peppermint (*Mentha piperita* L.), member of Lamiaceae family, is one of the most important medicinal plants. Considering the medicinal importance of peppermint and growth promotion activity of irradiated carrageenan, a pot experiment was conducted to investigate the effect of foliar feeding of different aqueous concentrations of radiation degraded carrageenan on growth, physiology, peltate glandular trichomes (PGTs) and essential oil production of peppermint. Crop performance was assessed 150 days after planting in terms of growth, physiological and biochemical attributes and production of menthol and menthone in peppermint. Characterization of carrageenan before and after irradiation was done by gel permeation chromatography (GPC), Fourier-transform infrared (FT-IR), Ultra Violet visible (UV-Vis) and nuclear magnetic resonance (NMR) spectroscopy. Among the various concentrations of irradiated carrageenan (IC) [0 (control), un-irradiated carrageenan (UIC), 40, 80, 120 160 and 200 mg L⁻¹ of IC], foliar application of 80 mg L⁻¹ of IC proved the best treatment followed by 120 mg L⁻¹ that gave maximal values for most of the attributes studied including essential oil content, menthol content and peltate glandular density. Thus, it may be concluded that the yield and quality of EO of peppermint may be improved by this economical, ergonomical, safe and novel technique.

Keywords: NMR, FT-IR, Menthol, PGTs, GC

INTEGRATED NUTRIENT, WEED, DISEASES AND PEST MANAGEMENT**AKANSHA DEORA¹, DEEPANSHI DEORA², ABHITEJ SINGH SHEKHAWAT³ & PUSHPENDRA SINGH⁴***¹Department of Plant Pathology, ²Graduation, ³Department of Soil Science & Agricultural Chemistry, ⁴Department of Horticulture, Rajasthan College of Agriculture, MPUAT, Udaipur.*

In agriculture, local varieties and practices are of low productivity, prone to pests and grown without proper fertilizer management resulting in poor yield and poor soil fertility. Modern technologies are often inappropriate due to lack of knowledge and training. However, a combination of traditional and appropriate modern technology like INM, IWM, IDM and IPM can reap a good harvest and support livelihood and nutritional security of farmers. Soils represent dynamic ecosystems and are the resources that provide humans with more than 90 % of all the food we eat. Our challenge is to manage soils in a sustainable fashion so that they will provide for human needs in future. Integrated Nutrient Management (INM) holds out great promise for meeting the growing nutrient demands of intensive

agriculture and maintaining crop productivity at higher levels. INM involves proper combination of chemical fertilizers, organic manure, crop residues, nitrogen fixing crops, pulses and oil seeds and bio-fertilizers suitable to agro ecosystem. Pathogens, weeds, and invertebrates cause significant crop losses worldwide and present a barrier to the achievement of global food security and poverty reduction. Integrated Pest Management (IPM) aims to protect agricultural crops from economic damage by insect pests, weeds, plant pathogens, and other harmful organisms, while reducing reliance on hazardous pesticides. Some cultural practices for organic IWM fulfil multiple functions. Diverse crop rotations reduce disease, insect pest and weed pressures, enhance beneficial habitat and balance nutrient demands on the soil. A farming system that utilizes an array of interdependent cultural, biological and herbicidal weed control practices is generally referred as Integrated Weed Management (IWM). Integrated Disease Management (IDM) involves the selection and application of a harmonious range of disease control strategies that minimize losses and maximizes returns. IDM can be considered at two levels. An integrated control program may be aimed at all of the diseases that affect a particular crop or an integrated control program may be developed for a specific disease that affects a crop.

EFFECT OF NATURAL AGENTS IN INCREASING PHOSPHATE AVAILABILITY TO UPLIFT CROP PRODUCTIVITY

AKANSHASINGH^A, ARCHANA VERMA^C, VIPIN KUMAR^A, LALI JAT^B, ANAND SINGH^A

Deptt. Of Soil Science and Agricultural Chemistry, SVPUAT Meerut-250110, (U.P.) , Deptt. Of Agronomy, SVPUAT Meerut-250110, (U.P.)

^AM.Sc. Deptt. Of Soil Science and Agricultural Chemistry, SVPUAT Meerut-250110, (U.P.)

Phosphate anion which is the least mobile element soil, precipitates as orthophosphate or is absorbed by Fe, Al and Ca ions, which makes it immobile. The concentration of bio-available P in soil solution is very low(1.0 mg kg⁻¹). Phosphorus solubilizing microbes enhancing its availability to plants through release from inorganic and organic soil P pools by solubilization and mineralization processes. Efficiency of P fertilizer throughout the world is low(10-25 %) and rest part gets wasted that's why PSB and plant growth promoting rhizobacteria (PGPR) are used, they together could reduce P fertilizer application by 50% without any significant reduction in crop yield. From the whole microbial population in soil, PSB constitute 1 to 50 %, while phosphorus solubilizing fungi (PSF) are only 0.1 to 0.5 %. Strains from bacterial genera *Pseudo-monas*, *Bacillus*, *Rhizobium* and *Enterobacter* along with *Penicillium* and *Aspergillus* fungi along with a nemato fungus *Arthrobotrys oligospora* are the groups of most powerful phosphate solublizers which has the ability to solubilize phosphate rocks. A gram of fertile soil contains 10¹ to 10¹⁰ bacterias. Phosphorus solubilizing activity leads to release metabolites such as organic acids, which through their hydroxyl and carboxyl groups which chelates the cation bound to phosphate and to other soluble forms of phosphates. The PSB dissolve the soil P through production of low molecular weight organic acids mainly gluconic and keto gluconic acids, which can also lower the pH of rhizosphere. Inorganic acids like hydrochloric acid can also solubilize phosphate but they are less effective compared to organic acids at the same pH. Phosphorus desorption potential of different car-boxylic anions citrate > oxalate > malonate / malate > tartrate > lactate > gluconate > acetate > formiate. Production of siderophores , acid phosphatase and alkaline phosphatase enzymes by plant roots or microbes hydrolyzes the soil organic P or split P from organic residues. Use of PSMs can increase crop yields up to 70 percent. *Pseudomonas* spp. enhanced the number of nodules, dry weight of nodules, yield components, grain yield, nutrient availability and up-take in soybean crop. Phosphate solubilizing bacteria. enhanced the seedling length of *Cicer arietinum*, while co-inoculation of PSM and PGPR reduced P application by 50 % without affecting corn yield. Inoculation with PSB increased sugarcane yield by 12.6 percent. Mycorrhiza along with *Pseudomonas putida* increased leaf chlorophyll content in barley. Seed yield of green gram was enhanced by 24 % following triple inoculation of *Bradyrhizobium* + *Glomus fasciculatum* + *Bacillus subtilis*. Integration of half dose of NP fertilizer with biofertilizer gives crop yield as with full rate of fertilizer; and through reduced use of fertilizers the production cost is minimized and the net return maximized.

Keywords: Phosphate, Organic acids, Phosphate Solubilizing Microorganisms (PSMs), Plant Growth Promoting Rhizobacteria (PGPR)

GENE EDITING AND CROP IMPROVEMENT USING CRISPR-CAS9 SYSTEM

AKASH GAURAV SINGH¹, TANUJA POONIA², TARA YADAV³

¹Department of Genetcs and Plant Breeding ,Navsari Agriculture University, Navsari. ²Department of Agronomy, College of Agriculture, S.K. Rajasthan Agricultural University, Bikaner. ³Department of Entomology, Rajasthan Agriculture Research Institute, Jaipur.

Advancements in Genome editing technologies have revolutionized the fields of functional genomics and crop improvement. CRISPR/Cas9 (clustered regularly interspaced short palindromic repeat)-Cas9 is a multipurpose technology for genetic engineering that relies on the complementarity of the guideRNA (gRNA) to a specific sequence and the Cas9 endonuclease activity. It has broadened the agricultural research area, bringing in new opportunities to develop novel plant varieties with deletion of detrimental traits or addition of significant characters. This RNA guided genome editing technology is turning out to be a groundbreaking innovation in distinct branches

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

of plant biology. CRISPR technology is constantly advancing including options for various genetic manipulations like generating knockouts; making precise modifications, multiplex genome engineering, and activation and repression of target genes. The review highlights the progression throughout the CRISPR legacy. We have studied the rapid evolution of CRISPR/Cas9 tools with myriad functionalities, capabilities, and specialized applications. Among varied diligences, plant nutritional improvement, enhancement of plant disease resistance and production of drought tolerant plants are reviewed. The review also includes some information on traditional delivery methods of Cas9-gRNA complexes into plant cells and incorporates the advent of CRISPR ribonucleoproteins (RNPs) that came up as a solution to various limitations that prevailed with plasmid-based CRISPR system.

Keywords : Genome editing technologies, guide RNA, Cas9 endonuclease

EFFECT OF ZINC AND SULPHUR ON WHEAT CROPS

AKASH KUMAR, PANKAJ CHAURASIYA, LAXMAN KUMAWAT AND S.P. SINGH

"Department of Soil Science & Agricultural Chemistry", Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut 250110

Zinc plays very important role in plant metabolism by influencing the activities of hydrogenase and carbonic anhydrase, stabilization of ribosomal fractions and synthesis of cytochrome. Plant enzymes activated by Zn are involved in carbohydrate metabolism, maintenance of the integrity of cellular membranes, protein synthesis, regulation of auxin synthesis and pollen formation. The regulation and maintenance of the gene expression required for the tolerance of environmental stresses in plants are Zn dependent. Its deficiency results in the development of abnormalities in wheat crop which become visible as deficiency symptoms such as stunted growth, chlorosis and smaller leaves, spikelet sterility. Micronutrient Zn deficiency can also adversely affect the quality of harvested products, wheat susceptible to injury by high light or temperature intensity and to infection by fungal diseases can also increase. Zinc seems to affect the capacity for water uptake and transport in wheat and also reduce the adverse effects of short periods of heat and salt stress. Sulphur is present in some amino acids and vitamins and required for the production of chloroplast. That's why sulphur is very important for photosynthesis in green plant as its presence in iron sulphur complexes of the transport chain. The deficiencies of sulphur first affect younger tissues of plant because sulphur is immobile in plants. The deficiencies of sulphur are reported as the appearance of these symptoms such as yellowing of plant leaves and stunted growth of plants. Sulphur deficiency significantly effects the production and quality of wheat.

Key words: environment, waste management,

MAJOR AGRICULTURAL PROBLEMS IN INDIA

AKASH TANWAR* RAM KISHAN BAIRWA**

Scholar, Department of Extension Education, Department of Horticulture, College of Agriculture, SKRAU, Bikaner (Raj.) India -334006

Small and fragmented land-holdings:-The seemingly abundance of net sown area of 141.2 million hectares and total cropped area of 189.7 million hectares (1999-2000) pales into insignificance when we see that it is divided into economically unviable small and scattered holdings. Seeds:- Seed is a critical and basic input for attaining higher crop yields and sustained growth in agricultural production. Distribution of assured quality seed is as critical as the production of such seeds. Unfortunately, good quality seeds are out of reach of the majority of farmers, especially small and marginal farmers mainly because of exorbitant prices of better seeds. Manures, Fertilizers and Biocides:- Indian soils have been used for growing crops over thousands of years without caring much for replenishing. This has led to depletion and exhaustion of soils resulting in their low productivity. The average yields of almost all the crops are among the lowest in the world. This is a serious problem which can be solved by using more manures and fertilizers. Irrigation:- Although India is the second largest irrigated country of the world after China, only one-third of the cropped area is under irrigation. Irrigation is the most important agricultural input in a tropical monsoon country like India where rainfall is uncertain, unreliable and erratic India cannot achieve sustained progress in agriculture unless and until more than half of the cropped area is brought under assured irrigation.

Key Word:- Agricultural production, manures and fertilizers etc.

DOUBLING FARMERS INCOME THROUGH COLD CHAIN NETWORK

AKKAMAHADEVINAIAK¹, ASHOKKUMAR². BAND L. MAHESH³

Department of Agricultural Extension, UAS, GKVK, Bengaluru-65

Agriculture is a backbone for Indian farmers because India is one of the largest producers and consumers of food products. This sector plays an important role in contributing to the development of rural economy. Domestically the spending on the food and food products

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

amounts to nearly 21 percent of gross domestic product of the country. The most important problem faced by the Indian agriculture is the highly inefficient supply chain. Because of lack of cold chain infrastructure and also food processing industry, about 50 percent of the food produces gets wasted and farmers are suffering from the distress sale. A well developed food processing industry is expected to increase farmers produce price, reduce wastages of fruits and vegetables, ensure value addition, and it also generate employment opportunities to the rural poor as well as export earnings and thereby helping farmers to increase their incomes. A Cold chain is the uninterrupted handling of the food product within a low temperature environment during the post harvest steps of the value chain including harvest, collection, packing, processing, storage, transport and marketing until it reaches the final consumer. Cold chain network will help to boost the farmers income by establishment of modern cold chain networks it not only reduces the food losses, but also empowers the farmers to reach across to more distant markets. As the cold storage facilities reduce the transpiration, the water content in the perishables is retained and causes less shriveling. Further it inhibits the ethylene production and slows down the ripening process of fruits. Efficient cold chain network reduces the post harvest losses and it generates additional income to the farmer. So It will be helpful the farmers to more market driven and profitable farming activities.

Keywords: Post harvest losses, Doubling farmers income and cold chain network

ENRICHED COMPOST AND ITS APPLICATION IN CROP PRODUCTION

AKSHAY KUMAR YOGI¹, RAKESH KUMAR².

Division of Agronomy, ICAR-IARI, Assam, ²Division of Agriculture Chemicals

The use of high analysis fertilizers has increased the crop productivity over the years. However, indiscriminate and non-judicious use of fertilizers has caused several ill-effects on soil health. Therefore, to sustain the productivity and soil health in long run, organic nutrient sources could be an alternative. However, due to lack of proper composting technique and low nutrient concentration in organic sources, their use is limited in crop production. The conversion of organic waste into the compost not only helps to enhance soil organic matter and efficient crop nutrition but also reduces environmental pollution and associated health risk. The enrichment of organic manure with nutrient enhances the crop productivity and nutrient use efficiency. The effectiveness of low grade rock phosphate (RP) could be improved through compost enrichment.. The enriched compost (EC) supplies a substantial amount of P and also helps in mobilizing the native pool of soil P. The recycling of rice residues through composting with RP and bio-inoculants serves as a supplemental source of plant nutrients. Application of enriched Farm yard manure (FYM) with inorganic fertilizers + plant growth promoting rhizobacteria (PGPR) enhances grain yield and improves the physico-chemical properties of soil. FYM enriched with non-edible oil cake resulted highest yield and economics in rice based cropping system. Application of EC enhances nutrient mineralization in soil. The use of microbial consortia for nutrient enrichment is a viable option to enhance nutrient concentration in organic manures. The use of EC for crop production could help in improving soil health and sustaining crop productivity.

Key word: Compost, nutrient, production, recycling, rock-phosphate, sustainable

EFFECT OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH AND PRODUCTIVITY OF HYBRID RICE

AKSHIKA BHAWARIYA¹ SHANKAR LAL SUND², TANUJA POONIA³, S. R. BHUNIA⁴

Department of Agronomy, College of Agriculture, S.K. Rajasthan Agricultural University, Bikaner.

Sustaining rice (*Oryza sativa* L.) productivity at high level is a great challenge, particularly in areas where rice productivity declines in spite of following recommended nutrient management practices. Nutrient management by integrating organic manures, inorganic fertilizers and biofertilizers may play an important role in improving and sustaining rice productivity. In this study, the authors tried to evaluate the suitable proportion of organic manures and inorganic fertilizers along with biofertilizer to maximize growth and productivity of hybrid rice on sandy-loam lateritic soils of West Bengal, India. The crop having 50% recommended dose of fertilizer (RDF) + 50% recommended dose of nitrogen (RDN) through mustard oil cake (MOC) and 75% RDF + 25% RDN through MOC + biofertilizer significantly increased plant height, number of tillers/m², leaf area index (LAI), dry matter accumulation (DMA) and crop growth rate (CGR) at initial and vital period of grain growth over those of 25% RDF + 75% RDN through MOC and 100% RDN through MOC. The former two treatments also increased number of panicles/m² and number of grains/panicle over those of only organic manuring (100% RDN) or only chemical fertilization (100% RDF) or 25% RDF + 75% RDN through MOC. Crop with 75% RDF + 25% RDN through MOC + biofertilizer or 50% RDF + 50% RDN through MOC produced 20.2%-33.8% higher grain yield and 11.0%-33.3% greater straw yield, and paid higher gross and net returns over other treatments. This study suggests growing hybrid rice with 75% RDF + 25% RDN through MOC + biofertilizer or 50% RDF + 50% RDN through MOC for better growth, higher productivity and greater profit.

Keywords : Nutrient management, biofertilizer, organic manuring, higher productivity

SUCCESSION OF POLLINATORS/VISITORS AND EFFECT ON YIELD OF FENNEL, *FOENICULUM VULGARE* (MILL.) AKSHAY KUMAR^{1*}, SACHIN KUMAR¹, POPIN KUMAR² AND KRISHNA KUMAR²

Department of Entomology¹,/ Department of Plant Pathology², Narendra Deva University of Agriculture and Technology Narendra Nagar, Kumarganj, Faizabad, (U. P.) 224229, India

Fennel, *Foeniculum vulgare* (Mill.) commonly known as *saunf*, is one of the most important winter season seed spices, grown in northern India. Fennel belongs to the family Apiaceae (Umbelliferae). Fennel crop is cross pollinated in nature. It revealed that the pooled averages of all the insect pollinators/ visitors, irrespective of species, on six observational hours (06:00, 08:00, 10:00, 12:00, 14:00 and 16:00 hrs. of the day) interval of observations were 1.50, 3.14, 1.52, 1.21, 1.39, 0.62 and 1.19 number of bees/branch/5 min., respectively. The succession of insect visitors was maximum at 08:00-10:00 hrs. followed by 06:00-08:00 hrs. of the day during all the three intervals. Irrespective of observational hours *Apis dorsata* was the most abundant visitors of fennel flowers i.e. 3.14 followed by *Apis cerana indica* 1.52 throughout the period of observation. The *Mesembrius bengalensis* 0.62, *Epasyphus balteatus* 1.21, *Coccinella spp.* 1.39 and *Polistes hebraeus* 1.19 were significantly lower than the *Apis dorsata*, *Apis floria* and *Apis cerana indica* 3.14, 1.52 and 1.50 respectively during 12:00 hours of the day were at per each other. The abundance of insect visitors was more during morning hours (06:00-10:00 hrs.) in the day and their population during afternoon hours (15:00-18:00) was comparatively less than the morning hours but abundance of pollinators at were very less during noon hours (12:00-14:00). The data on effect of bee pollination in different treatments on fennel flowers increases the yield. Effect on yield of fennel by bee pollination was 16.39 gram per plant while self-pollination and open pollination were 9.28 gram and 12.96 gram, per plant respectively. Bee pollination significantly against self-pollination and open pollination on fennel flowers under agro-ecological conditions of Kumarganj, Faizabad

COMPARATIVE PROFITABILITY ANALYSIS OF MUSHROOM AND VEGETABLE CULTIVATION: A CASE STUDY OF SOLAN DISTRICT OF HIMACHAL PRADESH

ALIYA NASIR¹, SUBHASH SHARMA², SAMRITI³ AND PARDEEPSINGH³

Department of Social Sciences¹, Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan (H.P.) - 173230

The present study was conducted in Solan district of Himachal Pradesh. A complete list of registered and non-registered mushroom growers was obtained from Department of Horticulture, Govt. of Himachal Pradesh and from the supplier of spawn and manure. A sample of 60 mushroom growers was drawn by using simple random technique from the list of mushroom growers for the collection of data. The average size of land holding was found to be 1.29 ha. When production, net return over total cost, gross return and output input ratio of mushroom were compared with tomato and found that there is more production of tomato but farmers' get higher price per unit for the mushroom than tomato and growing mushroom has been a profitable venture respectively. Comparative analysis for breakeven point revealed that growing mushroom had more benefit over tomato as it require lesser quantity to cover the total cost. Diversification in the agricultural activities is important to avoid the risk in production and to provide the food and nutritional security for population. Diversification in any farming system impact the sustainability, thus mushroom cultivation has enormous potential to improve food security and income generation, which in turn can boost rural economic growth regularly.

Key words: Mushroom, tomato, benefit, breakeven point, diversification

RESPONSE OF INTEGRATED FERTILIZER PRESCRIPTION AND YIELD TARGET ON YIELD OF CAULIFLOWER (*BRASSICA OLERACEA* L VAR. *BOTRYTIS*)

ALKAARYA AND SOBARAN SINGH

Department of Soil Science, College of Agriculture, G.B. Pant University of Agriculture & Technology, Uttarakhand- 263145, India

An experiment was conducted at Crop Research Centre during 2016-17 of G.B. Pant University of Agriculture and Technology Pantnagar, Udham Singh Nagar (Uttarakhand) to study the effect of integrated fertilizer prescription and yield target on yield of Cauliflower. The experiment was conducted in the Randomized Block Design (RBD) with ten replications of different doses of fertilizer and yield target as Control T₁, General Recommendation Dose T₂, Target Yield 1 (250 q ha⁻¹) T₃, Target Yield 2 (300 q ha⁻¹) T₄, Target yield 1 (250 q ha⁻¹) + 10 t ha⁻¹ FYM T₅, Target Yield 1 (250 q ha⁻¹) + 20 t ha⁻¹ FYM T₆, Target Yield 2 (300 q ha⁻¹) + 10 t ha⁻¹ FYM T₇, Target Yield 2 (300 q ha⁻¹) + 20 t ha⁻¹ FYM T₈, 10 t ha⁻¹ FYM T₉ and 20 t ha⁻¹ FYM T₁₀. These treatments were compared with general recommended dose. Results of this experiment indicated that treatment T₇ gave significantly higher yield followed by (T₈ > T₆ > T₄ > T₅ > T₃ > T₂) as compared to control (T₁). Treatments (T₇) and (T₈) gave significantly higher yield as compared to general recommendation (T₂). Treatment (T₉) and Treatment (T₁₀) were not showing significantly difference as compare to treatments T₁ and T₂. Among the two targets yield, target 300 t ha⁻¹ recorded relatively higher yield than target yield 250 t ha⁻¹ and it has also recorded significantly higher yields over general

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

recommended dose. Higher yield observed at higher target (300 q ha⁻¹) with 10 tonne FYM indicating the 300 q ha⁻¹ appropriate yield target for cauliflower. This might be due to balanced supply of nutrients from fertilizer, efficient utilization of applied fertilizer nutrients in the presence of organic sources and the synergistic effect of the conjoint addition of organic sources of nutrients. Efficient nutrient management is a prerequisite for achieving maximum yield in cauliflower with good curd quality. Neither the chemical fertilizers alone nor the organic manures exclusively sustain the productivity of cauliflower but a judicious combination of both along with their efficient management is potential tool for sustaining the productivity.

EXAGGERATIVE DEFENSE MECHANISM OF *BRASSICA JUNCEA* L. BY BRASSINOSTEROIDS (24-EPIBL AND 28-HOMOBL) TREATMENTS UNDER HIGH TEMPERATURE STRESS

ALKARAJPUT¹, SANDEEPKUMAR² AND GEETIKA SIRHINDI¹

Department of Botany, Punjabi University, Patiala-147002, Department of Botany, Deen Dayal Upadhyaya College, University of Delhi, Sector-3 Dwarka-110078

Agriculture represents a core part of the Indian economy and provides food and livelihood activities to much of the Indian population. While the magnitude of impact varies greatly by region, climate change is expected to impact on agricultural productivity and shifting crop patterns. Climatic changes and increasing climatic variability are likely to aggravate the problem of future food security by exerting pressure on agriculture. Increased concentration of greenhouse gases (GHGs) in the atmosphere resulted in warming of the global climate system by 0.74 °C between 1906 and 2005. The trends of rise in temperature, heat waves, droughts and floods, and sea level shown by the Indian scientists are in line with the Inter-Governmental Panel on Climate Change (IPCC) though magnitude of changes could differ. The mean temperature in India is projected to increase up to 1.7 °C in kharif (July to October) and upto 3.2 °C during rabi (November to March) season, while the mean rainfall is expected to increase by 10% by 2070. This increased temperature affects the agriculture productivity and shifting crop patterns in India. Adaptation of crop plants to environmental stresses is dependent upon the activation of cascades of molecular networks involved in stress perception, signal transduction and the expression of specific stress-related genes and metabolites. To mitigate the impact of high temperature on agriculture crops, biotechnological and breeding approach play a crucial role followed by physiological approaches (by applying phytohormone). Applications of Phytohormones has several advantages over the biotechnological and breeding approach like cost effecting and time saving and without altering the genome of crops. Presents study was pertaining to explore the role of 24-epiBL (brassinosteroids) in the mitigation of harsh effect of high temperature on *Brassica juncea* L. RLM 619 at physiological, biochemical and molecular level. In order to explore the ameliorating potential of BRs in plants particularly in agriculture crops like *Brassica juncea* L. subjected to high temperature stress with various concentrations of 24-epiBL. The morphology of *B. juncea* L. seedlings has revealed remarkable reduction under high temperature stress and 24-epiBL helps in ameliorating this reduction. Photosynthetic pigments such as chlorophyll and carotenoids decreased significantly in seedlings subjected to high temperature (25 °C to 45 °C). 24-epiBL helps in ameliorating photosynthetic ability by protecting chlorophyll and carotenoids content from high temperature stress. All concentrations ameliorate carbohydrate, vitamin C and Proline content in seedlings exposed to different temperatures as compared to control seedlings. Enzymes of antioxidant defense system ameliorate in 24-epiBL treated seedlings as compared to untreated control seedlings when exposed to different temperatures. Observation suggested that photosynthetic machinery reduce their efficiency under high temperature and 24-epiBL treatment helps in maintaining the efficiency of photosynthesis by increasing the activities of antioxidant enzyme followed by enhance level of osmolytes compounds. Improved health of plants with 24-epiBL at morphological level increasing activity of antioxidant enzyme followed by the enhance level of Vit. C and Osmolytes indicate, 24-epiBL can be used to mitigate the toxic effect of environmental stress in agriculture crops.

INTEGRATED FARMING SYSTEM: AN APPROACH FOR DOUBLING FARMERS' INCOME

ALOK KUMAR BEHERA¹, DEBASHIS NAYAK² AND JNANA BHARATI PALAI³

M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Agronomy, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha, Dept. of Agronomy, M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha

Indian agriculture has been shouldering the responsibility of providing food and nutrition to its teeming millions. After the advent of green revolution in late-1960s and economic liberalization in early-1990s, the farmers gradually started focusing on a few enterprises due to several imposing factors including shrinking farm sizes, fluctuating commodity prices, livelihood diversification and shortage of labour during peak agriculture season. An integrated farming system has been proved as an ideal system integrating physical, agronomic and socio economic milieus for development of eco-friendly, eco viably and environment sustainable farming in India and other countries of world. It is an indigenous agricultural practice aimed to develop eco-friendly farming system. There is reciprocal behavior in

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

utilization of waste products generated from different constituent entities of the system. Crop residues as dry fodder, feed grains and green fodder are derived from cropping system. Dung, manures, compost mixed of urine, dung and plants, as by products from livestock are used in enriching soils for best production. The goal of such integrated farming systems also encompasses the objective of conservation of existing natural resources and efficiently using them for sustainable growth of productivity as well as profitability to the farmers. The focus of present government is on doubling farmers' income by 2022. Hence, adoption of IFS is the right approach in this direction and should be supported through institutional, extension, policy and marketing interventions in a system approach.

Keywords: Doubling income, sustainable and integrated

PROSPECTS OF ECOTILLING IN CROP IMPROVEMENT

ALOK KUMAR SINGH*, GIRISH TANTUWAY, ADITI ELIZA TIRKEY

Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005

TILLING (Targeting Induced Local Lesions in Genomes), a reverse genetics tool of molecular biology that allows direct identification of mutations in a specific gene. EcoTILLING is a molecular technique that is similar to TILLING, with the exception that it uses natural genetic variation in contrast to induced mutations in TILLING. EcoTILLING is of special significance in species which are not amenable to chemical mutagenesis, thereby helping in detection of natural variants and their putative gene function. This approach allows rapid screening of samples possessing the gene of interest and identifies naturally occurring SNPs, small INDELS or both. The method has the potential to detect DNA polymorphisms (including variations in satellite repeat number) and determine heterozygosity levels within a gene fragment (in highly heterozygous outcrossing species). This reduces the time and effort for SNP discovery generally required by weeding out identical haplotypes. This method eliminates the requirement of otherwise cumbersome sequencing the genome of all individuals in a population to identify polymorphisms. Though, it has advantage of detecting multiple polymorphisms in a single fragment, it has not been widely employed as TILLING. EcoTILLING has been used to examine DNA variation in natural populations of black cottonwood; first large deciduous trees to have its genome completely sequenced. As the number of SNPs detected per fragment increases, the scoring and tracking of cleaved fragments becomes more difficult which is major challenge in the EcoTILLING. But one of the valuable applications of EcoTILLING is mining for variation in resistance genes to expedite the process of identifying alleles that could provide immunity to various diseases.

Keywords: TILLING, EcoTilling, SNPs

PLANT GROWTH RETARDANTS AS TOOL FOR ENHANCING GROWTH AND YIELD OF PULSES

AMANDEEP KAUR¹ AND HARMEET SINGH²

Department of Agronomy, PAU, Ludhiana¹ Professor, Department of Agronomy, PAU, Ludhiana

Pulses are the most significant food crops after cereals. Pulses are rich in proteins and found to be main source of protein to vegetarian people of India. Apart from being a sound source of protein, pulses also contain substantial amount of minerals, vitamins, crude fibre etc. Pulses being legumes, fix atmospheric nitrogen into the soil. Apart from nitrogen fixation pulses add organic matter into the soil in the form of leaf mould and they are generally used as green manure crops. The seeds, pods and leaves of pulses are used by human and livestock being rich in nutrition. They play an important role in crop rotation, mixed and intercropping, as they help maintaining the soil fertility. Pulses have more leafy growth and close spacing so they are helpful for checking the soil erosion. The deep rooting system helps in better extraction of water and nutrients from deeper soil layers, thus making them suitable for grown under rainfed conditions. Majority of pulses are short durational so that second crop may be taken on same land in a year, so they can fit easily in cropping systems and give ready cash to farmers. They provide raw material to various industries like Dal industry, Roasted grain industry etc. Pulses have indeterminate growth habit with low harvest index. The pronounced vegetative growth habit of pulse crops leads to the production of infertile or poorly productive branches with large number of unproductive flowers and pods, fruit drop and non synchronous flowering/fruitletting which poses a significant constraint to its productivity. So achieving a higher pod set and retention of sink is very important aspect. Therefore, pulses productivity can be substantially improved by curtailing excessive growth and flower or fruit drop. Plant growth regulators (PGR's) are organic substances which in small quantities increase or decrease or modify the physiological processes in plants which are finally expressed in the form of growth and development. Plant growth retardants are the chemicals substances that slows down the cell division and cell elongation of shoot tissue and regulate plant height physiologically without formative effects for example, AMO 1618, phosphon-D, CCC, MC and alar. These do not occur naturally in plants and acts in retardation of stem elongation, preventing cell division. Growth retardation is primarily induced by inhibition of gibberellins biosynthesis between ent-kaurene and ent-kaurenoic acid (Rademacher 2000).

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

IMPORTANCE OF BIOLOGICAL CONTROL AND ITS UTILIZATION

AMANDEEP*, RAJENDRA SINGH, HEM SINGH, SUNIL

Department of Entomology, SVPUAT, MEERUT (U.P.)

Biological control is defined broadly as the "use of natural or modified living organisms, genes, or gene products" to reduce the effects of pests and diseases. Biological control depends on knowledge of biological interactions at the ecosystem, organism, cellular, and molecular levels and often is more complicated to manage compared with physical and chemical methods. Today we have deteriorated the soil and human health with the excessive use of pesticides moreover pests now a days have become resistant. Only solution to this problem is to use new concept of Biological Control. We can achieve control of insect in a wide area and for longer period as bio control agent is prevalent till control is effective. Though initial cost is more but it is cheaper in a long run. Also, compatibility with other methods is very good. While using bio agents in any IPM programme care should be taken to use insecticides which are safe to natural enemies. With the use of biological control pests which are very difficult to manage otherwise are managed effectively. Biological control is the new emerging technique which will prove as a boon for farmers in recent time. Biological control application is completely safe to human as well as environment. It not only manage the pest effectively but also don't disturb the ecosystem by disturbing food chain. Biological control of insects are available for a variety of insects and in various formulations and are at par with the synthetic control measures if used at proper time and with right technique.

EFFECTS OF INTEGRATED NUTRIENT MANAGEMENT ON SOIL-CROPS SYSTEM

AMANPREET SINGH¹ AMAN DEEPRANGA² POONAM KUMARI^{1*}

¹Department of Horticulture, ²Department of Genetics and Plant Breeding, School of Agriculture, Lovely Professional University, Phagwara, Punjab-144411

Soil is a fundamental prerequisite for crop production as it provides plants with water and nutrients. A certain supply of mineral and organic nutrient sources is present in soils, but these often have to be supplemented with external applications, or fertilizers, for better plant growth. Fertilizers boost soil fertility and are applied to promote plant growth, improve crop yields and support agricultural intensification. Organic fertilizers are obtained from substances of plant or animal origin, such as manure, compost, seaweed and cereal straw. Organic fertilizers generally contain lower levels of plant nutrients as they are combined with organic matter that improves the soils physical and biological characteristics. The most widely-used mineral fertilizers are based on nitrogen, potassium and phosphate. Integrated Nutrient Management refers to the maintenance of soil fertility and the supply of plant nutrient at an optimum level for sustaining the preferred productivity through optimization of the benefits from all possible sources of organic, inorganic and biological components in an integrated manner. The aim of Integrated Nutrient Management (INM) is to integrate the use of natural and man-made soil nutrients to increase crop productivity and preserve soil productivity for future generations (FAO, 1995a). INM aims at optimal use of nutrient sources on a cropping-system or crop-rotation basis which encourages farmers to focus on long-term planning and make greater consideration for environmental impacts. INM relies on a number of factors which includes appropriate nutrient application, conservation and the transfer of knowledge about INM practices to farmers and researchers. INM practices also include new techniques such as deep placement of fertilizers and the use of inhibitors or urea coatings that have been developed to improve nutrient uptake.

"A STUDY ON GROWTH RATE AREA OF POTATO PRODUCTION IN UTTAR PRADESH."

AMAR SINGH¹ & K.K. MOURYA²

Assistant Professor, ITM University, Gwalior & ²Guest Faculty, NDU&T, Kumarganj, Faizabad, 224229.

Potato is a major food crop, grown in more than 100 countries in the world. According to FAO (2008), Potato is consumed by more than one billion people in the world. It is high quality vegetable cum food crop and used in preparing more than 100 types of recipes. The protein content of Potato has a high biological value than cereals and considered to be better than milk. Hence, Potato is supplementing meat and milk products by lowering energy intake and also by reducing food cost.

The present investigation entitled "A study on growth and instability of potato production in Uttar Pradesh." This study has been carried out to examine the trend and growth rate of potato area different periods in Uttar Pradesh.

The time series data on potato area in Uttar Pradesh, pertaining to periods 1977-78 to 2017-18, is used for investigation of trend and growth rate of potato area. The relevant statistical tools & technology like regression analysis etc. have been used for the purpose of investigation mentioned above.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

The results obtained from different statistical tools and technique shows that the growth rate of potato area has increased during all the decades.

Keywords: Statistical Tools, Regression Analysis, Trend and Growth Rate.

POTASSIUM MINING IN INDIAN SOIL

AMARJEET KUMAR¹, AJEET KUMAR¹, BIPIN BIHARI¹ AND HIMANSHU PATEL²

¹Department of Soil Science and Agricultural Chemistry, Bihar Agricultural University, Sabour, Bhagalpur, Bihar (813 210), India,

²Department of Soil Science and Agricultural Chemistry, Indira Gandhi Krishi Vishwavidyalaya, Krishak Nagar, Raipur, Chhattisgarh,

India Increasing population demands higher production and productivity of crops. Consequently, maintenance of soil fertility is a must for sustainable agriculture and future food security. FAO (2006) reported that India registered an ever recorded food grain production of 230 mt with a consumption of 23 mt of NPK's during 2007-08 and it was estimated that about 45 mt of nutrients are needed to produce 300 mt of food grains by 2025 to sustain the requirement of growing population. Out of these macronutrients (NPK), Potassium is probably the most pertinent nutrient that has been potential of significantly affecting agricultural production in the India (Sanyal *et al.* 2014). Present intensive production systems in India characterized by heavy removal and inadequate replenishment of Potassium resulted in Potassium deficiency and depletion of soil Potassium reserves. Historically low application rates of K in crops have led to over-dependence on the native soil reserve of K (Sarkar *et al.* 2014). For sustaining the crop productivity and to restore the soil fertility, there is a need to arrest depletion of soil Potassium reserves for which understanding of crop nutrient balances is important. There were many attempts to examine the potassium mining at the individual plot level, long term fertilizer experiments, state level and country level. In most of these reports, fertilizer inputs and crop removals were only considered, thus resulting in the large scale negative Potassium balances in Indian agriculture. Srinivasarao *et al.* (2011) were found that by considering all these inputs and outputs, the Potassium balance in Indian agriculture is about 3 million tones per year. In agroecosystem, Potassium is contributed by many sources like animal manure, crop residue, compost, rice burning residue, irrigation water and rain etc. Similarly, besides crop Potassium removal, Potassium is lost to deeper layers by rain or irrigation water by leaching. This total balance can be further refined by considering area under conservation agriculture, green leaf manuring like *Glyricidia* and other non-conventional sources of potassium being used in Indian agriculture, which may further reduce the overall negative balance of K Indian agriculture.

Key words: Potassium mining, Human population, Reserve potassium, Sustainable agriculture

RESPONSE OF TRANSPLANTED PIGEON PEA (*CAJANUS CAJAN* (L.)MILLSP.) CV. BSMR-736 TO DIFFERENT PLANTING GEOMETRY

¹UMBARKAR S.D., ²AGLAVE B.N. AND ³SATHE R.K.*

Department of Agronomy, College of Agriculture, Latur, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani (MH)

The field investigation entitled "To study the Response of Transplanted pigeon pea (*Cajanus Cajan* (L.) Millsp.) cv. BSMR-736 to different planting geometry" conducted at Department of Agronomy, College of Agriculture, Latur. The soil was clayey in texture, moderate in available nitrogen, low in available phosphorus, high in available potassium and moderately alkaline in reaction. The environmental conditions prevailed during experimental period was favorable for normal growth and maturity of pigeonpea crop. The experiment was laid out in RBD with three replication and seven treatments and 21 plot, the gross and net plot size of each experimental unit was : 7.2 x 5.40 M² and 5.40 x 3.60 M² respectively. The treatments were T₁ Dibbling of seed 90 cm x 20 cm, T₂ Transplanting 90 cm x 20 cm, T₃- Transplanting 90 cm x 30 cm, T₄ Transplanting 90cm x 60 cm, T₅ Transplanting 120 cm x 30 cm, T₆ Transplanting 120 cm x 60 cm, T₇ Transplanting 120 cm x 90 respectively.

Transplanted pigeonpea at 90 x 20 cm was significantly higher grain yield (2149 kg ha⁻¹) over all of the treatment. The second best was ... at 90 x 30 cm (1977 kg ha⁻¹). Lowest seed yield was recorded by treatment of pp at 120 x 90 cm (1412 kg ha⁻¹), The B:C ratio was maximum with Treatments at 90 x 20 cm.

(Keyword: transplanting, pigeonpea, planting geometry, land configuration, economics)

DOUBLING OF FARMER INCOMES THROUGH PRECISION FARMING OF VEGETABLE CROPS

AMIT KR. SINGH,¹ S.C. PANT², S. RAVI³ AND A. K. SINGH⁴

^{1&2}Department of Vegetable Science and ³Department of Plant Pathology, College of Horticulture VCSG UHF Bharsar, Pauri Garhwal, Uttarakhand-246123. ⁴KVK, Pratapgarh-239408.

Although cereal-based diet is the characteristic feature of Indian foods habits, the recent trend is diet shift towards the inclusion of more

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

vegetable in diet provide a needful opportunity to farmers to grow more vegetable, vegetable farming is also provided a continuous source of cash with good use of land particularly for small and marginal farming. Doubling of farmers income depend on to the farm's income which emphasized the need to make the substantial changes in the farming practices by adopting precision vegetable farming. Most of the Indian farmer's inputs applying in excess amounts like more use of fertilizers, pesticides, and seeds which leads to losses of crop production sustainability and land deterioration. Precision farming is a site-specific management practices, it's delivering the idea of doing the right thing, at the right place and at the right time. Precision farming provides a way to mechanize site-specific management using information technology and providing the substitutes information to manage the farm inputs. It's can assist in managing crop production inputs in an eco-friendly way to the long-term sustainability of vegetable production, confirming that it should reduce environmental loading by applying inorganic chemicals. Precision farming benefits to the environment comes from the more targeted use of inputs that reduce losses from excess applications farm inputs and from the reduction of losses due to nutrient imbalances, weed escapes, insect damage, etc. which will be resulted from raised two to four-fold farm incomes.

PLANT BREEDING FOR DROUGHT RESISTANCE

AMIT KUMAR CHAUDHARY¹, HAMSAPPOORNA PRAKASH¹, SURAJ KUMAR HITAISHI¹ AND ABHINAV KUMAR²

Department of Genetics and Plant Breeding, College of Agriculture¹, Department of Horticulture, College of Horticulture and Forestry², Narendra deva University of Agriculture and Technology Kumarganj Faizabad

Drought stress is the most prevalent environmental factor limiting crop productivity, and global climate change is increasing the frequency of severe drought conditions. Drought resistance' (DR) is a broader term applied to plant species with adaptive features that enable them to escape, avoid, or tolerate drought stress. Drought escape' is the ability of a plant species to complete its life cycle before the onset of drought. Thereby, plants do not experience drought stress, as they are able to modulate their vegetative and reproductive growth according to water availability, essentially through two different mechanisms: rapid phenological development and developmental plasticity. Drought tolerance' (DT) is the ability of plants to endure low tissue water content through adaptive traits. These adaptive traits involve maintenance of cell turgor through osmotic adjustment and cellular elasticity, and increasing protoplasmic resistance. Improvement of yield and maintaining yield stability of crops, under normal as well as drought stress conditions, is essential for the food security of the growing global population. It is difficult to resolve the role of different components of DR in the stability of the crop yield as the major objective. However, there exist a variety of different mechanisms for drought escape, avoidance, or tolerance in natural populations that can improve DR and maintain grain yield in crop plants. In nature, extreme DR is found in resurrection plants which possess strong drought escape mechanisms.

Keywords : Drought stress, tolerate, phenological development etc.

INTER-SPECIFIC HYBRIDIZATION IN *CUCURBITA* SPECIES: CHALLENGES AND ACHIEVEMENTS

AMIT KUMAR MATHUR*, AND RAHUL KUMAR MEENA

Division of Vegetable Science, Indian Agricultural Research Institute, New Delhi, India

Genus *Cucurbita* is an economically important group of vegetables grown worldwide. This genus has the highest genomic number among all cultivated cucurbits which is $2n=40$. It consists of 27 species. Among them, most commonly cultivated species are *C. moschata*, *C. pepo*, *C. maxima*, *C. mixta* and *C. ficifolia*. *C. moschata* occupies a central position among the annual species. It includes crops such as squash, pumpkins, and gourds. The wild species of this genus possesses resistance to various biotic and abiotic stresses. Inter-specific hybridization is an important technique for gene transfer from a wild relative species (*Cucurbita lundelliana*, *C. mixta*, *C. ficifolia* etc.) to another cultivated genotype. In general, success of hybridization within genus *Cucurbita* is a species-dependant. For example, good quality flesh from *C. maxima* to *C. moschata*, bushy growth habit from *C. pepo* to *C. moschata*, disease resistance from *C. lundelliana* or *C. martinii* to *C. moschata*. F_1 hybrids can be obtained from most inter-specific matings, usually with difficulty. The main problems are the crossing barriers and the male sterility of the F_1 and subsequent generations. Techniques like *in vitro* pollination and fertilization, embryo rescue, bridge lines, somatic hybridization, and manipulation of ploidy level have been utilized successfully to overcome these barriers. Therefore, different *Cucurbita* species can be utilized to develop many varieties with desirable traits by employing inter-specific hybridization, if cross compatibility is achieved between the wild and cultivated species.

Key words: *Cucurbita*, Inter-specific hybridization, wild relative species

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**IMPACT OF DROUGHT IN CHICKPEA****AMIT KUMAR¹, SHENDE R. T.¹ AND ROSHAN SHINDE²**¹Sardar Vallabh Bhai Patel University of Agriculture and Technology, Meerut, UP; ²Indira Gandhi Agriculture University, Raipur, India;

Chickpea is a cool season legume traditionally grown under rainfed conditions globally. The crop is exposed to drought stress due to recent changes in climate conditions. The major chickpea-growing areas are in the arid and semiarid zones. Chickpea generally faces terminal drought, increasing towards the end of the growing season, due to the depletion of soil moisture; or intermittent drought, caused by a break-in rainfall followed by insufficient rains during the growing season. Approximately 90% of the world's chickpea is grown under rainfed conditions where terminal drought is one of the major constraints limiting productivity. Terminal drought stress is typical in the post-rainy season in semiarid tropical regions where crops grow and mature on a progressively depleting soil moisture profile. Flowering and pod setting in chickpea are the stages of development that are most sensitive to drought stress. A number of yield components including dry matter and harvest index of rainfed chickpea were less in plants exposed to drought stress than irrigated plants. Seed yield losses due to drought range from 30% to 100% depending on genotype and the type of drought experienced in the target environment. There is a need to develop new high throughput phenotyping techniques and/or physiological, biochemical or molecular markers that determines reproductive function. Future research should focus on screening germplasm collections to quantify genetic variability and identify the drought tolerant genotypes for use in breeding programs.

SEASONAL INCIDENCE OF *SCIRPOPHAGA INCERTULAS* (WALKER) ON BASMATI-1 IN WESTERN PLAIN ZONE OF UTTAR PRADESH.**AMIT RANA¹, RAJENDRA SINGH¹ S. K. SACHAN¹ D.V. SINGH¹ GOPAL SINGH¹, VIVEK³, ARUN KUMAR¹ AND SUCHARU SINGH¹**¹Department of Entomology, ²Department of Plant Pathology, ³Department of Agronomy, College of Agriculture, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut-250110 (U.P). India.

The present investigation was carried out to study the at Crop Research Center of Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut. The yellow stem borer, *S. incertulas* (Walker) was recorded as major pest. The incidence of *S. incertulas* (Walker) was recorded on the incidence of yellow stem borer *Scirpophaga incertulas* (Walker) showed that it was recorded on 26th standard week for the first time and continued till second week of November i.e. 46th standard week. The infestation of stem borer recorded as dead heart/ white ear head ranged from 0.85 to 15.25 per cent during the crop season *Kharif* 2017, and positive correlated with all the other weather parameters.

ECO FRIENDLY MANAGEMENT OF YELLOW STEM BORER, *SCIRPOPHAGA INCERTULAS* (WALKER) ON BASMATI-1 IN WESTERN PLAIN ZONE OF UTTAR PRADESH.**AMIT RANA¹, RAJENDRA SINGH¹ S. K. SACHAN¹ D.V. SINGH¹ GOPAL SINGH¹, VIVEK³, ARUN KUMAR¹ AND SUCHARU SINGH¹**¹Department of Entomology, ²Department of Plant Pathology, ³Department of Agronomy, College of Agriculture, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut-250110 (U.P). India.

The present investigation was carried out to study the “Eco friendly management of yellow stem borer, *Scirpophaga incertulas* (Walker) on paddy in western plain zone of Uttar Pradesh” in randomized block design with three replications and seven treatments at Crop Research Center of Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut. The yellow stem borer, *S. incertulas* (Walker) was recorded as major pest. Efficacy of different insecticide Fipronil 5 % SC (Regent) @ 50 ml a.i., Thiamethoxam 25 % WG, Evident, @ 25.0 g. a. i., Lambda cyhalothrin 4.9% CS, Matador, @ 12.5 ml a.i., *Trichogramma japonicum* @ 1.0 lack/ha, *Beauveria bassiana* @ 2.5 kg /ha, *Metarrhizium anisopliae* 4.7 × 10⁸ spores. @ 2 g/lit. of water and control, was tested against *S. incertulas* (Walker). Fipronil 5 % SC (Regent) @ 50 ml a.i. was found most effective treatment in reducing the dead hart as well as white ear formation as it was 2.1-3.0 percent after 21 days of 1st and 2nd application, respectively the next best treatment were Thiamethoxam 25 % WG, Evident, @ 25.0 g. a. i. and Lambda cyhalothrin 4.9% CS, Matador, @ 12.5 ml a.i. with 3.65 and 3.13 percent dead hart formation, respectively after 21 days both the spray. The higher yield (46.15q/ha) and cost benefit ratio (1: 9.45) were also obtained from Fipronil 5% SC. *Trichogramma japonicum* was found safer to spider population followed by *Beauveria bassiana*.

ROLE OF PLANT PHYSIOLOGY FOR ADVANCES IN AGRICULTURE**AMIT KUMAR SHUKLA¹, ANKIT KUMAR PANDEY², ROHIT KUMAR SINGH³, PINGIDI SOUJANYA⁴***Faculty of Bhagwant University, Ajmer, Rajasthan, 305 004*

Plant physiology is a sub discipline of botany concerned with the functioning, or physiology, of plants. Closely related fields include plant morphology (structure of plants), plant ecology (interactions with the environment), phytochemistry (biochemistry of plants), cell biology, genetics, biophysics and molecular biology. Fundamental processes such as photosynthesis, respiration, plant nutrition, plant hormone functions, tropisms, nastic movements, photoperiodism, photo morphogenesis, circadian rhythms, environmental stress physiology, seed germination, dormancy and stomata function and transpiration, both parts of plant water relations, are studied by plant physiologists. Crop yield is controlled by the interaction between the genetic potentialities of crop plants and the environment in which they grow. Variations in the genotype and in the environment, including weather and cultural practices, act through physiological processes to control growth. Thus the physiological processes of plants are the machinery through which both the genetic potentialities and the environment operate to produce the quantity and quality of growth or phenotype which we term yield. In a brief consideration of the relation borne by plant physiology to agricultural development it will be possible merely to call attention to some of the more important improvements in the art of agriculture that have resulted from the development of plant physiology, and to indicate some of the more important directions in which this science may affect the agriculture of the twentieth century. It will be necessary to call attention briefly to the origin of our cultivated plants, the discovery of the sexuality of plants, the discovery of the nature and sources of plant food, and the nature and causes of plant diseases. It will be desirable also to consider briefly that the training in plant physiology required for the investigator, the teacher, and the farmer.

Key Words: Agriculture, Plant Physiology, Crop, Yield, Advances etc.

COMBINING ABILITY (GCA & SCA), HETEROSIS OVER BETTER AND ECONOMIC PARENTS AND INBREEDING DEPRESSION ANALYSIS IN YELLOW SARSON (*BRASSICARAPA* VAR. *YELLOW SARSON*)**AMIT TOMAR AND MAHAK SINGH***Department of Genetics & Plant Breeding, Chandra Shekhar Azad University of Agriculture & Technology, Kanpur-208002, U.P., India.*

The experimental materials were comprised 25 lines namely, YSC-63, YSC-41, B-09, YSK-71, YSKM-11-02, YSC-76, YSKM-10-1, YSKM-11-1, YSC-75, YSKM-10-02, YSK-9-01, YSC-80, K-88, YSC-15, Type-42, YSC-18, YSK-03, YSC-21, YSC-92, YSC-45, YSC-30, YSC-95, YSC-40, YSC-46 and YSC-46 used as female and 4 testers namely, NRCYS-05-02, YSH-401, YST-151 and Pitambari (check) used as male of yellow sarson. The materials comprising of 29 parents + 100 F₁s + 100 F₂s were sown in Randomized Block Design with three replications during *Rabi* 2014-2015 at Oilseed Research Farm, Kalyanpur of C.S. Azad University of Agriculture & Technology, Kanpur-208002. All the Twenty five females were crossed with each of four males in line x tester mating designs to produce sufficient amount of F₀ seeds of 100 crosses during the *Rabi* season 2011-12 to raise the F₁s. The F₁s were selfed in order to obtain F₂s seeds during the *Rabi* season 2012-13. The parents were also maintained through selfing in a Randomized Block Design (RBD) with three replications at the Oilseed Research Farm, Kalyanpur of Chandra Shekhar Azad University of Agriculture and Technology, Kanpur. Each treatment was planted in one row, of 3 m length and 45 cm apart, Plant to plant distance was maintained at 15 cm by thinning. All the recommended agronomic practices were adopted for raising a good crop. The observations were recorded on eight characters namely; number of siliquae per plant, number of seeds per silique, biological yield per plant (g), harvest index (%), 1000-seed weight (g), oil content (%), protein content (%) and seed yield per plant. The analysis of variance for combining ability was carried out according to the method outlined by Kempthorne (1957). The oil content (% seed weight) and protein content (% de-oiled meal weight) was estimated by using Nuclear Magnetic Resonance (NMR) method. The analysis of variance indicated significant differences among the treatments for all the characters. Parents vs. F₁s, parents vs. F₂s and F₁s vs. F₂s also revealed highly significant differences for all the characters except harvest index and oil content. The estimate of σ^2_{D} were lower than σ^2_{E} for all the characters. The analysis of variance for combining ability were found significant differences for all the characters except biological yield per plant in F₁ and F₂ generations. The parents namely, YSC-41, B-09, YSC-76, YSKM-11-1 and YSKM-10-02 were found common good general combiners in both F₁ and F₂ generations based on gca effect and *per se* performance for seed yield per plant. The cross combinations namely, YSC-63 x YSH-401, YSC-41 x NRCYS-05-02, YSC-41 x YST-151, B-09 x YSH-401 and B-09 x YST-151 were found common good specific combiners in both F₁ and F₂ generations on the basis of sca effects and *per se* performance for seed yield per plant. The cross combinations namely, B-09 x YST-151, YSKM-10-02 x YST-151, YSC-15 x YST-151, YSC-30 x YST-151 and YSC-84 x YST-151 were shown desirable and significant heterotic response over better and economic parent and high inbreeding depression for seed yield per plant.

Key words: Better parent, combining ability, gca, heterosis, inbreeding depression, sca and yellow sarson.

ROLE OF ENDOPHYTIC MICRO-ORGANISMS IN BIOLOGICAL CONTROL OF PLANT DISEASES**AMRITPAL MEHTA¹, ASHWANI KUMAR BASANDRAI², VAKUL SOOD¹, JITENDER SHARMA¹, RAKESH KUMAR³**¹Division of Plant Pathology, SKUAST, Jammu-180009, India, ²Department of Plant Pathology, CSKHPKV, Palampur-176062, India³Division of Vegetable Science & Floriculture, Jammu-180009, India

Plant pathogens include fungi, bacteria, viruses are the most visible threats to sustainable food production. The total annual worldwide crop loss from plant diseases is about \$220 billion. The decreasing efficacy of the chemical as well as risks associated with residues on the plants have highlighted the need for a more effective and safer alternative control measures. In recent years, endophytes have received increasing attention as a promising supplement or alternative to chemical control. Endophytic micro-organisms (fungi and bacteria) that colonize internal plant tissues without causing visible damage to their hosts. Endophytic bacteria penetrate via stomata, lenticels, root hairs, root cracks, tissue wounds and become systemically disseminated in the host plant, actively colonizing the apoplast. Fungal endophytes invade plant tissue by direct penetration, via appresoria formed on cuticle or via natural openings or through wounds. Fungal endophytes inhibit plant pathogen by producing antibiotics and lytic enzymes secreted by endophytes, indirect effects by induction of plant resistance and stimulation of plant secondary metabolites and ecological effects. Fungal endophytes protect plant against pathogens by phytoalexins production. Plant growth promoting bacteria protect plant directly by inducing plant growth and indirectly by the production of phytohormones, through production of antifungal or antibacterial agents, siderophore production, nutrient competition and induction of systematic acquired host resistance, or immunity or by enhancing availability of minerals. Endophytes as bio control agents are effective, economically viable, practically applicable and environmentally safe. So that endophytes have enormous potential as biocontrol agents and reiterate the need for concerted efforts to obtain more basic information about endophyte biology before they can be used effectively for biocontrol.

SCREENING OF VARIOUS BOTANICALS IN THE MANAGEMENT OF *RHIZOCTONIA BATATICOLA* (*MACROPHOMINAPHASEOLINA*) INCITANT OF DRY ROOT ROT OF MUNGBEAN (*VIGNARADIATA*)**ANAM CHOUDHARY AND SHABBIR ASHRAF**

Department of Plant Protection, Faculty of Agricultural Sciences, Aligarh Muslim University Aligarh-202002, India

Present experiment was conducted to study the various phytoextracts for their efficacy against *Rhizoctonia bataticola* (*Macrophomina phaseolina*) causing dry root rot of mungbean. Plant extracts of ten different plant species, viz. Garlic, Turmeric, Neem, Ginger, Onion, Amla, Castor Tobacco, Betel and Fennel were used at three different concentration 10%, 20% and 30%. In vitro inhibitory effect of the various botanicals were tested on the mycelial growth of *Fusarium* by using poison food technique. The pathogen were inoculated into the media separately previously and incubated for seven days. In general, all the test botanicals controlled the mycelial growth to varying degrees. Radial growth of *Rhizoctonia bataticola* was recorded. The growth inhibition increase with the increase of concentration of all the plant extracts. Highest mycelial growth inhibition was recorded with garlic extract at 30% concentration (100%) followed by 91.80% and 80.52% at concentration 10% and 15% respectively. Other botanicals also exhibited antifungal activity at varying percentage. The results of the experiment suggested that the use of garlic extracts are effective for minimizing dry root rot incidence of mungbean. Calotropis and castor were found least effective against the fungus. The present study revealed that these botanicals could be exploited for the eradicating this pathogen accordingly, this is an important proactive measure in preventing the spread of the wilt disease through a more ecofriendly and sustainable approach.

- Keywords: Mungbean, *Rhizoctonia bataticola*, botanicals.**STUDY ON POPULATION DYNAMICS OF MUSTARD APHID *LIPAPHIS ERYSIMI* (KALT.) IN RELATION TO WEATHER PARAMETERS****ANAM ZIA AND MASARRAT HASEEB**

Department of Plant Protection, Faculty of Agricultural Sciences, Aligarh Muslim University.

Mustard aphid *Lipaphis erysimi* (Kalt.) is the most serious pest and considered as restrictive factor in cultivation of mustard causing 35-96% reduction in yield depending upon weather conditions. The study was carried on population dynamics of mustard aphid on mustard in relation to weather parameters which was studied during rabi 2015-16 cropping season. The study will provide an opportunity to face the pest challenge and their timely management. The natural appearance of mustard aphid was observed from 3rd standard week and lasted up to 11th standard week however a change in their number is being observed in both the consecutive year. The study revealed that population of mustard aphid reaches its peak in 7th standard week with an increasing temperature and decreasing humidity, however correlation coefficient shows a contradictory result between population dynamics and weather parameters.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

SCIENCE & TECHNOLOGY IN AGRICULTURE

ANAND KUMAR AND ASHOK KUMAR GODARA

Department of Extension Education, CCS Haryana Agricultural University, Hisar-125004 Haryana (India)

In addition to water scarcity and increasing land degradation, Indian farmers are vulnerable to impacts of climate change as their livelihood largely depends on monsoon, markets and intermediaries who are integral part of their lives but are unpredictable and play havoc on rural livelihoods. With the agricultural growth rate hovering around 3% annually, farmers have felt severe economic distress and hence the clarion call by the Prime Minister to Double Farmers' Incomes by 2022.

However, this will be a challenge given increasing fragmentation of holdings, extreme weather events, rising input costs and post-harvest losses. It is where challenges are greatest that we require the very best that human innovation can offer. The government has already placed a clear focus on farmers' welfare with policies to enhance water availability (Har Khet ko Pani), increased water use efficiency (more crop per drop), better farm practices, improving soil health, increasing investment in agriculture research, extension and support prices, creating rural infrastructure, ensuring timely delivery of credit and technology, encouraging market reform (e-NAM) and reducing risk in agriculture through the introduction of a new insurance scheme (PMFBY). A draft strategy paper released by the Ministry of Agriculture and Farmer Welfare targeted to raise the average annual income of a farmer household in India to Rs. 2,19,724 by 2022-23, from Rs. 96,703 in 2015-16, with the help of additional public and private investment of Rs. 6.4 lakh crore. Research and technology with the support of pragmatic policies, targeted budget allocations and convergence of schemes based on agro-ecologically focused growth engines will be key to realizing this vision.

Key words: Science, Technology, Agriculture

AN EFFECTIVE WAY TO PROMOTE SUSTAINABLE AGRICULTURE THROUGH ORGANIC FARMING

ANAND KUMAR*, RADHA KAUSHIK**

**Department of Genetics and Plant Breeding C.S. Azad University of Agriculture & Technology, **Department of Biotechnology C.C.S. University Meerut (U.P.)*

The conservation of natural resources is critical for the agricultural sector which ensures long-term sustainability. The rigorous reliance on chemical fertilizers and pesticides always questions the concept of sustainability in its all aspect. The use of chemicals in farming have serious long term effects on the environment. These chemicals contaminating soil and water sources, and enters in to the food chain. In addition to this, when cattle consume foliage that contains these chemicals become highly concentrated in the flesh and milk of dairy cows. Ultimately, it creates serious health problems to people who consume dairy products. Organic agriculture avoids all kinds of practices which damages agro-ecosystem. It provides healthy food while establishing an ecological balance to prevent soil fertility or pest problems. In order to alleviate all environmental and social problems arising from chemical based farming, the promotion of organic farming is indispensable. A shift to organic agriculture brings about significant changes: restricted use of synthetic fertilizers and pesticides, increases of other inputs such as organic materials, labor, perhaps machinery, cultural practices (e.g., crop rotation), and better knowledge of biological processes. These changes have serious implications. The concept of organic agriculture builds on the efficient use of locally available resources, and on the use of adapted technologies ex: To improve soil fertility, biodiversity and sustainability of agricultural production, To conserve natural resources, To improve agronomic and economic performance, to make yields more stable, especially in risk-prone tropical ecosystems, to achieve better food quality and food security, To provide access to attractive markets through certified products, To create new partnerships within the whole value chain as well as to strengthen self-confidence and autonomy of the farmers. The possibilities are identified regarding potential of organic farming to promote sustainable agriculture in India: 1. As India now in the initial stage of organic farming, the quantity produced not enough to feed the large Indian population. Under this situation, concentrating on the export aspect of organic farming is more suitable opportunity for India 2. Optimization of the potential trade in organic products is one of the good opportunities for improving the conditions of agricultural sector of India. Through the export of organic agricultural products, India can improve the conditions of Indian farmers as well as the entire agricultural sector 3. Organic farming can be adopted as one of the strategy for sustainable agriculture promotion with a long term perspective to foster community institutions that meet employment, environmental and health needs of the society 4. Institutional barriers to the development of the organic sector are needed to be resolved with proper strategy and execution 5. The traditional and indigenous farming knowledge should be conserved, while introducing selected modern technologies to manage and enhance diversity into farming systems. The increasing awareness about the safety and quality of foods, long term sustainability of the present farming system persuades sustainable agriculture practices. The organic farming has emerged as an alternative system of farming which not only address the quality and sustainability concerns, but also ensure profitable livelihood option for rural community of India. As India in the initial phase of Organic farming, strong institutional mechanisms and governmental support must be essential to realize its sustained growth. Strong Local institutions build up including farmers Group, Local Guidance, knowledge sharing, market linkages etc. are critical to build up successful growth of organic farming.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**“EFFECT OF GAMMA RADIATION IN CV. NOVALUX AND PRAHA OF GLADIOLUS”****ANAND S. RAWAT, B.D. BHUJ, R SRIVASTAVA, S.C. SHARMA, N.K. SINGH***Department of Horticulture, College of Agriculture, GBPUA&T, Pantnagar U.S. Nagar, Uttarakhand-263145*

The present investigation was conducted at Model Floriculture Centre, G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand, during 2017-18. The investigation was laid out in factorial concept of randomized block design (RBD) in open field condition. The objective of investigation was to study the effect of various doses of gamma irradiation on different cultivars and their interaction effect on plants and the identification of desirable mutants for quality and agronomic characters. The medium sized corms were used as experimental material from the two gladiolus cultivars viz. 'Nova Lux' and 'Praha' irradiated with gamma rays of various doses viz. 0.0 Kr (control), 4.0 Kr, 4.5 Kr, 5.0 Kr, 5.5 Kr, 6.0 Kr and 6.5 Kr. The observations were recorded from whole plant population. According to the findings a random reduction in survival percentage of plants were found at higher doses of gamma rays in all the cultivars. The gamma irradiation showed an inhibitory effect viz. days to emergence, plant height, number, length and width of leaves, in all the cultivars when irradiated with gamma rays. The early flowering and increment in blooming duration were recorded at higher doses. The number of tillers and corms increased with increased doses of gamma rays whereas number and size of floret, spike length, rachis length, vase life, water absorption, weight and size of corms and cormels were reduced. The plants were unable to produce flower spike between 5.0 Kr to 6.5 Kr of gamma rays. Mutation spectrum and frequency were found highest in 'Praha' and most of the variations were observed in the form of chimeras and abnormalities. Some desirable mutants were identified in all the cultivars. Erratic and non-directional changes were observed due to gamma irradiation.

EVALUATION OF CUSTOMIZED FERTILIZERS IN RESPECT TO YIELD, SOIL NUTRIENTS STATUS, UPTAKE AND ECONOMICS OF WHEAT (*TRITICUM AESTIVUM* L.) UNDER EASTERN UTTAR PRADESH.**ANAND SINGH¹, NEERAJ KUMAR², PRAMOD KUMAR³, BHAVYARAJ PANDEY⁴ AND AKANSHA SINGH¹***Soil Science & Agril. Chemistry, SVPUAT, Meerut, Assistant Professor, Soil Science & Agril. Chemistry, NDUAT, Faizabad, Agronomy, CSAUAT, Kanpur, Soil Science & Agril. Chemistry, NDUAT, Faizabad*

Customized fertilizers can improve productivity and sustain soil health and fertility. The present research was conducted was conducted at Agronomy Research Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during Rabi 2015-16 in randomized block design with four replications and the treatment consisted of T₁ (control), T₂ (RDF), T₃ (Soil test-based recommendation), T₄ (Indo-Gulf Customized Fertilizer), T₅ (TCL Customized Fertilizer) and T₆ (Farmer's Practice). The soil of experimental field was silt loam texture, low in organic carbon (0.38%) and low in available nitrogen (151.76 kg ha⁻¹), phosphorus (14.75 kg ha⁻¹) and medium in potassium (248.00 kg ha⁻¹) and low in sulphur (9.00 kg ha⁻¹), zinc (0.50ppm) and boron (0.46ppm). The grain and straw yield (q ha⁻¹), uptake of nitrogen, phosphorus, potassium, sulphur, zinc and boron were maximum under T₃, which was at par with T₄ and T₅ and significantly superior over T₁, T₂ and T₆. The maximum grain yield of wheat (46.64 q ha⁻¹) was recorded with T₃ which was significantly higher over than T₁ (20.08 q ha⁻¹), T₆ (30.78 q ha⁻¹) and T₂ (38.10 q ha⁻¹) while at par with T₅ (43.92 q ha⁻¹) and T₄ (44.97 q ha⁻¹). The grain yield of wheat was increased with the treatment T₃ 22.41% and 51.53% over T₂ and T₆ respectively. Similarly, 3.71% and 6.19% over T₄ and T₅ respectively. The yield difference between both the customized fertilizers was not up to the level of significance. Variation in availability of nutrients was observed under most of the treatments due to different nutrients management. The higher availability of nutrient was observed under all the treatments except control and farmer's practice. The availability of S, Zn and B were maintained under customized fertilizers treatment and soil test-based recommendation. While, maximum depletion was observed in control and farmer's practice. Maximum net return (Rs. 43828 ha⁻¹) and B:C (0.95) were calculated in T₃ followed by T₄ (net return Rs. 39078 ha⁻¹ and B:C 0.82) and T₅ (net return Rs. 36925 ha⁻¹ and B:C 0.78).

Key words: Customized fertilizers, TCL, Indo-Gulf, ppm.

EFFECT OF ORGANIC MANURE AND INORGANIC FERTILIZERS ON GROWTH AND LEAF YIELD OF *ALOE VERA* (L.) AT FARMER FIELD**ANANT KUMAR, SATYAPRAKASH, VIRENDRA PAL, PK MADKE, ARVIND KUMAR AND JOGINDER SINGH***K.V.K., Ghaziabad, (SVPUA&T, Meerut)*

An experiment was conducted at farmer field during 2016-17 in the Dist. Ghaziabad UP. to study "Effect of organic manure and inorganic fertilizers on growth and leaf yield of *Aloe vera* (L.)" in a factorial randomized block design to find out the effect of organic manure (farmyard manure) and inorganic fertilizers (nitrogen and sulphur) alone and combine application of farmyard manure, graded levels of nitrogen and sulphur on growth and leaf yield of *Aloe*. The quintessence of results relating to the mean data revealed that the treatments involving combination of higher levels of FYM, nitrogen and sulphur viz: farmyard manure at 25t. per hectare along with nitrogen 60kg/ha and sulphur 18kg/ha., recorded the highest leaf yield (48.45 t./ha). The leaf yield increases are different growth parameters viz:

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Plant height, plant spread, number of leaves per plant, leaf length, leaf thickness and leaf width. The enhanced leaf yield due to combined application FYM, nitrogen and sulphur: FYM increased the uptake of nitrogen and sulphur.

IMPACT OF MICRO IRRIGATION TECHNIQUES ON HORTICULTURE PRODUCTION.

ANANT RAMSINGH, SUSHANT KUMAR¹ AND SATENDRA KUMAR

Department of Horticulture, ¹Department of Entomology, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut

Micro irrigation is defined as the frequent application of small quantities of water directly above and below the soil surface usually as discrete drops, continuous drops or tiny streams through emitters placed along a water delivery line. It can also be defined as the application of water at low volume and frequent interval under low pressure to plant root zone. Drip irrigation, also known as micro irrigation or trickle irrigation, applies water slowly, directly to the soil around the crop. Drip irrigation generally uses less than half the water of overhead and furrow irrigation. Efficiency with drip irrigation exceeds 90% where as a sprinkler system is between 50 to 70% efficient. The impacts of micro irrigation technologies indicate that they are usually promoted primarily for saving water in irrigated agriculture and averting the impending water crises. Micro irrigation technologies lead to poverty reduction through substantial increases in farm income due to an increased area of cultivation, better crop yields, enhanced output quality, early crop maturity and hence higher unit prices, and reduced cultivation costs, particularly for operations like irrigation and weeding. Micro irrigation technologies enhance nutritional security by enabling the production and consumption of vegetables, particularly leafy vegetables, which are usually missing in the traditional staple diets of many cultures. Study the performance of drip irrigation on growth and development of horticultural crops. The study revealed the effect of drip irrigation treatment on growth and development of mango, sapota and cashew nut. It was found that the treatment 40 litres water day⁻¹ plant⁻¹ through drip was found superior than all other other treatment in respect of height (30.33), canopy (1043) and diameter (2.92) stem of mango plant. In respect of sapota plant, treatment 60 litre water day⁻¹ plant⁻¹ was found satisfactorily superior in respect of height (28.4), canopy (787) and diameter (2.82) stem of sapota plant.

DOUBLING FARMER'S INCOME THROUGH INNOVATIVE AND AGRONOMICAL APPROACHES

ANIKET DIWEDI[†] AND BHAWANI SINGH PRAJAPAT[^]

CCSHAU, Hisar-125004, Haryana, [^]MPUAT, Udaipur- 313001, Rajasthan

Agriculture is the largest enterprise in the country. Indian agriculture suffers from low productivity, low quality awareness and rising imports. Farmer in distress, to alleviate the distress farmer's incomes need to increase substantially. Indian agriculture has grown at less than 2% compound annual growth rate in last five year. Agriculture sustains livelihood for more than half of the country's population. Doubling income in a short period is a daunting task. The government of India in its annual budget of 2016-17 set a policy target of doubling farmer's income by 2022 by constituting Dalwai committee through seven point strategies: adequate institutional arrangement to mitigate risk and crop loss; irrigation-Per Drop, More Crop; quality seed; soil-test-based nutrient management-Distribution Soil-health card; post harvest losses- investment in warehousing and cold chains; value addition; creation of a national agriculture market, removing distortion and e-platform across 585 markets; new crop insurance scheme: Pradhan Mantri Fasal Bima Yojana, minimum premium and maximum security; promotion of ancillary activities such as, poultry, beekeeping, fisheries, mushroom and integrated farming system module. Major sources for enhancing farmer's income through agronomic interventions should address the challenges of reducing the cost of cultivation as well as increasing the productivity of the farm. Other innovative technologies like encourage contract farming, convert the top 10 agriculture universities into centres for excellence to make region-specific strategies to raise crop yields, advise on the creation of integrated supply chains, and prepare plan to promote exports and cut imports.

Key words: Drip, Organic farming, e-NAM, Contract farming, Value addition and Allied activities

SEED AND SEED QUALITY: A BASIC UNIT FOR PRODUCTION

ANIL KAPOOR^{1*}, MINAKSHI SERAWAT², AND VIJAY KANT SINGH³

¹Department of Agronomy, GB Pant Uni. of Agriculture & Technology, Pantnagar-263145, ^{2,3}Department of Soil Science, GB Pant Uni. of Agriculture & Technology, Pantnagar-263145

Seed is the basic fundamental unit of agriculture. We can define the seed as the fertilized ripened ovule of a flowering plant containing an embryo and capable normally of germination to produce a new plant. The production of the agriculture or horticulture is mostly depends upon the quality of seed. Hence the seed quality plays an important role in a production management system. Basically the quality of seed is governed by its characteristics which bear itself like genetic potential, physical health and chemical composition. The good quality seed should bear moral characters which are high genetic purity, high physical purity, high germination ability, high vigor, better establishment, free from pest and disease, good physical appearance, high longevity / shelf life, Optimum moisture content for

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

storage, High market value. The maintenance and improvement of seed quality is big challenge in field condition. There are certain recommendations regarding to seed quality during seed production in field conditions which are monitors and governs by organizing bodies. There are also several laws and acts are playing important role in maintaining seed quality like seed act (1966). Generally there are five types of seeds which are developed and produced by an organization or agency. Nucleus seed, Breeder seed, foundation seed, registered seed and certified seed. The quality seed should be fulfilled the criteria of standard quality seed, generated by an organization or agency, which produced under the basics of Seed legislation and follows the process of seed certification.

ROLE OF HOUSEHOLD PRACTICES IN INSECTICIDES DECONTAMINATION IN CHILLI (*CAPSICUM ANNUUM* L.)**ANIL KUMAR JASWAL^{1*}, S K PATYAL² AND VIKRAM SINGH³***YSP, UHF Nauni-173230 Solan, Himachal Pradesh*

The crop losses in the world would have been estimated around 40 per cent, if pesticides were not used in agriculture. However, the presence of pesticide residues in food commodities has become a major cause of concern. Vegetables are highly beneficial for the maintenance of human health or prevention of diseases. India is a major producer, exporter and consumer of chilli in the world. The chilli crop suffers major quantitative and qualitative loss in production due to chilli thrips, *Scirtothrips dorsalis* Hood and yellow mite, *Polyphagotarsonemus latus* (Banks). To control these pests malathion, dimethoate, ethion and methyl parathion are sprayed on the crop. But data generated by "Monitoring of Pesticide Residues at National Level" revealed presence of acephate, cypermethrin and profenofos residues in chilli fruits throughout the country. Hence, in view of the possible health hazards posed by these insecticides to the consumers, the study on the role of household practices in the decontamination of these insecticides from chilli fruits was carried out in the Department of Entomology, Y S Parmar University of Horticulture and Forestry, Nauni, Solan (HP) during the year 2014. Acephate, cypermethrin and profenofos were sprayed on chilli crop at single dose of 560, 50 and 500 g a.i.ha⁻¹, respectively and at double dose of 1120, 100 and 1000 g a.i.ha⁻¹, respectively. Different decontamination practices such as tap water washing, lukewarm water washing, saline water washing, vinegar water washing and tamarind water washing were used and found effectively in removing residues from chilli fruits upto 45.07, 48.96, 58.85, 53.54 and 54.12 per cent, respectively. The study concluded that saline water washing was found most effective (upto 58.85%) in dislodging insecticide residues.

Key words: chilli, residue, acephate, cypermethrin, profenofos, decontamination

EFFECTIVENESS AND OPINION OF AGRI-EXTENSION PERSONNEL ABOUT IT AS AN EXTENSION ADVISORY TOOL: A CASE STUDY**ANIL KUMAR MALIK^{1*}, KRISHAN YADAV² AND BABU LAL DHAYAL³**

Department of Extension Education, College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, India, 125004, Directorate of Extension Education, Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, India, 125004, Department of Extension Education, College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, India, 125004.

E-extension as a modern method of communication can be used to enhance the effectiveness and efficiency of extension services for agricultural sustainability. E-extension is the delivery of extension services using the internet and the latest information communication technologies (ICTs), which allow networking, online sharing, and collaboration. Agri-Extension personnel are a major factor in conducting an effective agricultural extension work plan; therefore, understanding extension personnel opinion towards the use of E-extension is important. So, the present investigation was conducted in CCS Haryana Agricultural University, Hisar. A total of 108 respondents (23 from main campus and 85 from outstation) were included in the sample of study. Primary data was collected using a self administered questionnaire and analyzed with the help of SPSS using descriptive statistics (Percentage, mean, rank order, standard deviation etc.). The results of the study revealed that internet has enhanced the practice of extension and personal contact adjudged as a most effective extension tool with a mean score of 4.19.

Keywords: E-extension, Agri-Extension personnel, Opinion, Internet, Effectiveness.

POSSIBILITIES OF DIFFERENT TYPE OF PLASTIC MULCHES IN LADAKH REGION**ANIL KUMAR, VIKAS GUPTA¹, T.H. MASOODI AND D. NAMGYAL¹***High Mountain Arid Agriculture Research Institute-Leh, SKUAST-Kashmir, ¹Krishi Vigyan Kendra, Leh, SKUAST-Kashmir*

Ladakh is cold arid desert area at high altitude has limited access to improved agricultural technologies in changing climatic situation especially low and high temperature during winter and summer, shrinking of water resources, lower fertility level of soil, wind velocity and attack of insect pest etc. Mulching is an essential cultural technique that can reduce the amount of work inherent in gardening,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

helping to produce healthier plants and potentially increasing vegetable yields. Mulch is often defined as any material applied to the soil surface as cover. It can be divided into two general groups organic and inorganic. Mulching is the process of covering the soil surface around the plants with an organic or inorganic material to create micro climate for plant growth, development and efficient production. Importance of different type of mulches viz., Black mulches it does not allow sunlight pass through the soil, it is especially used for weed control, clear or transparent mulches is good for soil solarization and inhibits the growth of soil borne diseases, yellow plastic mulch is attracts certain insects and thus acts as a trap for them, white colour is cools the soil, silver colour mulch is cools the soil and repels some aphids and thrips, red colour mulch is partially translucent and allows radiation to pass through and warm the soil.

OVERCOME DEMAND OF PEOPLE BY PRESERVATION AND PROCESSING OF FOOD

ANIL SHARMA, A. S. SUNDURI, AMIT KUMAR, M K SHARMA AND J P RATHORE

Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K)

India is the second most populated country in the world with seventh largest geographical area of around 3,166,414 sqkm. To fulfil the basic food requirement of whole country thorough planning and management is required. Food preservation and processing plays an important role in fulfilling food requirement of the country. Food preservation has become a part and parcel of the life of a common man. Food preservation is inevitable owing to many reasons. Some foods such as fruits and vegetables are available in specific seasons and not in others, while other foods are more abundantly available in some season than in others. In some places there is a surplus production of a food product, whereas in other places there is an inadequate supply. Foods can also be perishable (likely to decay or go bad quickly) and semi-perishable including juicy fruits, vegetables, mangoes, tomato, papaya and many more, which very quickly get spoilt. To promotion of food processing industries in the country which would result in reduction in post-harvest losses, efficient storage and transportation, processing, increase in shelf life of food products, availability of fresh and processed products at reasonable prices to consumers and better income to the farmers. Food preservation plays an important role in our life. To understand the challenges of food preservation, we need to understand the varied topography and climate of the state. Today, food preservation is very important to fulfil the food supply needs of a developing country like India. It also ensures that the food is available and its supply is maintained at all times. Furthermore, problems like food shortage or famine can also be avoided.

GENETIC BIO-DIVERSITY SURVEY AND COLLECTION OF *ALLIUM SP.* IN INDIA

ANIRUDHAKUMAR SHARMA RASHMI NIGAM AND J. SINGH

GENE FLOW IN SEED PLANTS

ANIT KR. SINGH¹, RAJESH KR. GUPTA²

M.sc. Ag Student, Deptt. Of Ag. Genetics & Plant breeding J.V. College Baraut U.P - 250611, Deptt. Of Ag. Genetics & Plant breeding, J.V. College Baraut U. P - 250611

Gene dispersal (flow, or migration) within and between plant populations has been of continuous interest to plant breeders and seed producers for many decades. Economic considerations have stimulated studies of gene flow as a function of distance, breeding system, pollinating agent, and planting design in numerous domestic plants. Only during the past two decades have a large body of plant evolutionists become interested in information accruing from these studies, and in the rates of gene flow in wild populations. Their efforts have concentrated primarily on related problems such as adaptations for and mechanics of pollen and seed (or fruit) dispersal, adaptive radiation in pollination and seed dispersal mechanisms, and colonization and the alteration of species boundaries. Early in this

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

century, anecdotal evidence on the movement of pollen and seed vectors, dispersal of pollen by water, and the range extensions of weed species led to the casual assumption that gene flow must be extensive, and that it must play a major role in the cohesion of populations and population systems.

Keywords : Gene Flow, Seed Dispersal, Pollen Concentration, Seed Plant and Neighborhood Size.

FOLIAR FERTILIZATION FOR INCREASING NUTRIENT USE EFFICIENCY AND CROP PRODUCTION

ANITAARYA

Department of Agronomy, G. B. Pant University of Agriculture & Technology, Pantnagar-263145. U. S. Nagar, Uttarakhand. India

Foliar fertilization is a technique of feeding plants by applying liquid fertilizer directly to their leaves. Foliar fertilization is gaining importance in recent times for increasing crop yields and nutrient use efficiency. Foliar feeding has been used as a means of giving supplemental doses of nutrients. The overall economics of foliar fertilization is dependent on how successful applications are and whether or not the same nutrition might have been supplied more economically through another mean, plant hormones, stimulants and other beneficial substances. We observed the effects of foliar fertilization like yield increases, resistance to diseases and insect/pests, improved drought tolerance and enhanced crop quality. Foliar applications are often timed to coincide with specific vegetative or fruiting stages of growth. Applications may also be used to aid plants in recovery from transplant shock, hail damage or the weather extremes. The soil application of any fertilizer including organic and commercial forms for higher crop production may be relatively inefficient due to biological, chemical, and physical properties of the soil that can decrease nutrient availability. Increasing costs of commercial fertilizers (nitrogen, phosphorus, and potassium) also make their non-traditional fertilizer applications, specifically foliar fertilization is more attractive, but can foliar fertilization take care of all the plant's nutrient needs. Foliar fertilization is generally used for better management of vine nutritional status, for growth, to correct deficiencies quickly, to improve disease resistance, for frost mitigation and to enhance crop quality.

FOOD PROCESSING AND VALUE ADDITION TECHNOLOGIES FOR IMPROVED FOOD SAFETY

ANITA*, TULSIRAM JANGIR*

Department of Horticulture, College of Agriculture, Bikaner, SKRAU, Bikaner, 334006 Rajasthan (India)

Food processing is the transformation of raw ingredients, by physical or chemical means into food, or of food into other forms. Combines raw food ingredients to produce marketable food products that can be easily prepared and served by the consumer. Value addition as a process of increasing the economic value and consumer appeal of a commodity with special reference to horticultural crops, Value addition is an important factor in the growth and development of the horticultural sector, both in India and around the world. The increase in global population during the past two centuries has made food processing one of the most deliberated subjects in the food value chain. The need for processed food is expected to increase even further when the global population increases further. Environmental concerns related to food processing that require consideration, such as the use of fossil fuels and the disposal of residual matters of food processing, will have to be reviewed. That can be used by industries to enhance the use of environmentally friendly technologies for food processing and enhance value addition.

Keywords : Value addition, Food safety, Economic value

MODERN CONCEPT OF CROP PRODUCTION IN AGRICULTURE

ANJALI JINGAR

College of Agriculture, Agriculture University, Jodhpur (342304)

In the traditional agriculture, increase in foodgrain production used to be through increase in area under cultivation and good cultural practices. In scientific crop production, increase in foodgrain production is expected through improved cultivars and recommended crop production technology. Modern crop production emphasises two more dimensions: time and space. Time concept related to increase the cropping intensity to 200, 300 and 400 per cent per year under irrigation by growing two, three and four crops respectively where only one crop used to be grown. In drylands, where there is no scope for increase in cropping intensity, the other concept of space can be applied. The land equivalent area can be increased by practising allied components of cropping in vertical dimension (multi-tier system). Activities such as dairying, poultry, sericulture, biogas, edible mushroom production, agroforestry etc assume critical importance in supplementing farm income. Integrated farming system (IFS) appears to be the answer to the problem of increasing food production and farm income of the small and marginal farmers with limited resources without any adverse effect on environment and agroecosystem. By integrating different agricultural and allied enterprises with cropping activity, the byproducts of cropping activity can be recycled for minimising cost of crop production leading to profitable farming. The future of Indian agriculture, therefore, appears to depend on the development out of appropriate farming systems as applicable to resource poor farm families in different agroecological situations.

GENETIC EVALUATION OF BAJRA- NAPIER HYBRIDS FOR NITRATE CONTENT UNDER MID HILL REGION OF HIMACHAL PRADESH**ANJALI KUMARI^{1*}, V.K. SOOD¹, SAWAN KUMAR¹ AND PRIYANKA¹***Department of Crop Improvement, College of Agriculture, CSK Himachal Pradesh Krishi Vishavidyalaya, Palampur (H.P.)- 176062*

Nitrate is an important source of nitrogen in plants for their growth and development but the accumulation of nitrate in large amount causes acute poisoning in the ruminants. It enters the bloodstream of the animals and combines with the ferrous ions. This creates oxygen deficiency by converting hemoglobin to met-hemoglobin which results in mortality and abortions in the ruminants. In order to assess the low nitrate content, 18 different frost tolerant Bajra- napier hybrid genotypes along with two checks were evaluated at CSKHPKV, Palampur during *Kharif* season. Significant variability for nitrate content was observed among all the genotypes studied. Mean values for nitrate content ranged from 373-1420 ppm with genotype NDFB 8 × FD 433 (373 ppm) having lowest nitrate content and genotype CO-7 × FD 464 (1420 ppm) having maximum nitrate content. High PCV (45.08), GCV (45.07) along with high heritability (99.71) coupled with high genetic advance as percent of mean (92.85) was found for nitrate content indicating the presence of additive gene action suggesting that the selection for this trait would be effective. On the basis of mean performance, genotype BAIF Bajra × FD 483 was found to be promising with high green fodder yield (604.33 g) and low nitrate content (385 ppm).

INHERITANCE OF *FUSARIUM* WILT RESISTANCE AND CERTAIN MORPHOLOGICAL CHARACTERS IN CASTOR (*RICINUS COMMUNIS* L.)**ANJANA PANERA^{*}, JALU, R. K., H. B. VIRANI***Department of Genetics and Plant Breeding, College Of Agriculture, Junagadh Agricultural University, Junagadh-362 001, Gujarat, India*

An experiment was consist of ten parents and six hybrids involving both parents as resistant, one parent resistant and both parents susceptible were screened for wilt reaction under wilt sick plot condition at Main Oilseeds Research Station, Junagadh. Observations were recorded as per cent disease infection in each genotype periodically at thirty days interval upto 150 days after sowing. Out of sixteen castor genotype screened, nine accessions were found to be *fusarium* wilt resistant with less than 20 per cent wilt incidence. The range of disease incidence was from 0.00 to 100 %. The hybrids, SKP-84 x SKI-215 and JI-368 x SKI-215 involving both resistant parents were showing resistant reaction against wilt, while other four hybrids involving at least one susceptible parent were wilt susceptible under wilt sick plot. Monogenic nature of inheritance was observed for stem colour (mahogany dominant over green and red), internode nature (elongated dominant over condensed), leaf shape (flat dominant over cup), bloom nature (triple dominant over double and single), spiny nature of the capsule (spininess is partially dominant over non-spininess), types of flowers on the primary raceme (monoecious dominant over interspersed and pistillate), shape of the raceme (conical dominant over cylindrical) and compactness of spike suggested that there was the hierarchy of genes for expression could not be judged. Genotypes should be screened for further confirmation of wilt resistance and inheritance of morphological characters. In order to get supporting results for inheritance of morphological traits, related methods should be carried out.

Keywords - Castor, Inheritance, Fusarium wilt, Morphological character

ECOFREINDLY BIOPESTICIDES*** ANJANA, KUJUR¹; VINITA, PARTE² AND URVASHI, MARKAM¹***Rajmata Vijayaraje Scindia Krishi Vishwa vidyalaya, Gwalior, MP.INDIA , ²College of Agriculture, Ganjbasoda, Vidisha, JNKVV, Jabalpur, MP, INDIA*

Bio pesticides are certain types of pesticides that are derived from natural materials like plants, bacteria, fungi and virus, and certain minerals. Integrated Pest Management (IPM) is an effective, long term, environmentally sensitive approach to pest management. Agricultural practices such as application of fertilizers and pesticides were developed long ago but with great progress. Modern agricultural practices like chemical pest control will yield good production. So we have to protect our environment from the harmful chemicals. Biopesticides was used as a component of Integrated Pest Management programme, Bio pesticides promotes growth of healthy crops with least disruption to ecosystem, these bio pesticides can greatly decrease the use of conventional pesticides, while crop yields remain high. Bio pesticides are usually inherently less toxic than conventional pesticides and are effective in very small quantities and decompose quickly resulting in lower exposures, no residues and environment friendly. Bio pesticides are Safer to use for plants and animals.

Key words- Integrated Pest Management, toxic, environment, ecosystem, Bio pesticides.

WEED MANAGEMENT IN SUSTAINABLE AGRICULTURE**ANJU BIJARNIA***Agronomy at agriculture university, Kota, Rajasthan*

Sustainable crop production is necessary to ensure global food security and environmental safety. Sustainable agriculture (SA) is gaining popularity around the globe to its sustainable approaches such as permanent soil cover, minimal soil disturbance, plant crop rotations and integrated weed management. Weed control is the biggest challenge to SA adoption. Weed ecology and management is different in SA than in conventional agriculture. In SA, weed expression, seed bank status, distribution, dispersal mechanism, diversification, growing patterns and competition trends are complex and differ from conventional systems. It is due to reduced tillage of the soil and the flora that thrives in SA. reduced tillage systems affect efficacy of herbicide and mechanical weed control measures. Weeds dominating SA and their responses to SA components are highlighted. Integrated weed management compatible to cropping patterns and climatic conditions offers the best result in SA.

ROLE OF MICRONUTRIENTS IN ENHANCING QUALITY FRUIT PRODUCTION OF FRUIT CROPS**ANKIT DONGARIYAL, RAJAT SHARMA AND DC DIMRI***Department of Horticulture, College of Agriculture, G.B. Pant University of Agriculture & Technology, Pantnagar (Uttarakhand)*

Due to wide eco climatic conditions India is a horticulture rich country producing wide range of fruit crops along with other horticultural crops. In India fruit crops cover 31.5% of total production share among various horticultural crops. Proper nutrient management is essential for optimizing quality production of fruit crops. Although, macronutrients (N, P and K) play a key role in plant metabolism but micronutrients (B, Ca, Fe, Zn, Cu,) are equally important for various plant activities and quality fruit production, in spite of being applied in micro quantities. Micronutrients are generally foliar sprayed as it is quick, more effective and common practice to overcome micronutrient deficiency in order to improve fruit quality. Different micronutrients have key role in various plant metabolisms which together contributes to increased yield and quality. Boron (B) is responsible for increasing flowering and fruiting, fruit set, activate salt absorption, sugar translocation and carbohydrate metabolism. Calcium (Ca) is important for quality of fruits since it is required for cell division and elongation. It increases TSS and fruit firmness, consequently prolongs shelf life by slower softening during long term storage at low temperature. Iron (Fe) forms important enzymes and is associated with chlorophyll synthesis. As zinc (Zn) is precursor of auxin so its application delays the formation of abscission layer during early stages of fruit development and increases fruit set. Copper (Cu) promotes formation of Vitamin A, chlorophyll and accelerates evolution of ethylene during ripening of fruits. The rate of photosynthesis increases due to higher absorption of CO₂ in presence of Cu. Foliar application of these micronutrients alone or in combination can enhance production by increasing yield and quality.

EFFICACY OF DIFFERENT COATING MATERIALS ON POST HARVEST CHEMICAL PARAMETERS OF GUAVA (*PSIDIMUM GUAJAVAL*.)**ANKIT DONGARIYAL, NAVIN SINGH AND RAJAT SHARMA***Department of Horticulture, College of Agriculture, G.B. Pant University of Agriculture & Technology, Pantnagar (Uttarakhand)*

Guava (*Psidium guajava* L.) is one of the most important tropical and subtropical fruit crop grown throughout the world. It is highly nutritious and contains high amounts of vitamins A, B₁ (Thiamine), B₂ (Riboflavin) and C (Ascorbic acid). Despite having high nutritive value, its market is limited due to short post harvest shelf life with poor quality fruits. Keeping in view the above consideration, the present investigation was conducted to study the response of different coating materials on post-harvest changes in guava at successive intervals of storage. Fruits of winter season were harvested and treated with different treatments i.e. T₁: Aloe vera gel @ 15%, T₂: Aloe vera gel @ 20%, T₃: Aloe vera gel @ 25%, T₄: Ascorbic acid @ 750 ppm, T₅: Ascorbic acid @ 1000 ppm, T₆: Ascorbic acid @ 1500 ppm, T₇: benzyl adenine @ 50 ppm, T₈: benzyl adenine @ 100 ppm, T₉: benzyl adenine @ 200 ppm and T₁₀: the untreated i.e., control. In all the treatments, the chemical attributes increased upto 6 days and then gradually decreased during storage. The shelf life of fruits in all treatments was extended as compared to control. Among all the treatments tested, TSS was found maximum (9.69°Brix) in T₁₀ (control) treatment whereas acidity was lowest (0.33%) in the fruits treated with T₇ (benzyl adenine @ 50 ppm) treatment. The treatment T₂ (Aloe vera gel @ 20%) reported maximum reducing sugar (3.55%), total sugar (8.27%) and ascorbic acid (133.94 mg/100g edible pulp) content. Coating provides a protective barrier around fruit which checks respiration rate and slows down the metabolic processes which consequently increases shelf life with quality of fruits.

EFFECT OF BIODEGRADABLE MULCHES ON STRAWBERRY CULTIVATION**¹ANKIT GAWRI, ²ASHOK DHAKAD***Department of Horticulture, CCS, Haryana Agriculture University (CCSHAU), Hissar-125004, Department of Horticulture, CCS, Haryana Agriculture University (CCSHAU), Hissar-125 004*

The performance, the degradability in soil and the environmental impact of biodegradable starch-based soil mulching and low tunnel films were assessed by means of field and laboratory tests. The lifetime of the biodegradable mulches was 9 months and of the biodegradable low-tunnel films 6 months. At the end of the cultivation period, the biodegradable mulches were broken up and buried in the field soil together with the plant residues. Biodegradation in soil or compost depends on a complex synergy of biological and abiotic degradative processes. One year after burial, less than 4% of the initial weight of the biodegradable film was found in the soil. The radiometric properties of the biodegradable films influenced positively the microclimate: air temperature under the biodegradable low tunnel films was 2 °C higher than under the low density polyethylene films, resulting in an up to 20% higher yield of strawberries. This review discusses the physicochemical and structural properties of biodegradable plastic mulches, examines their potential for on-site decomposition in light of site-to-site variance due to environmental and biological conditions, and considers the potential for longterm effects on agroecosystem sustainability and functionality.

Keywords: Strawberry, biodegradable, microclimate, agroecosystem

ORGANIC FARMING IN A FRUIT CROPS**ANKIT KUMAR PANDEY¹, VED PRAKESH² AND ASHOK KUMAR PANDEY³***Department of Horticulture (Fruit and Fruit Technology), BAU, Sabour-813 210, Bhagalpur, Bihar (India), ²Department of Agronomy, Bihar Agricultural University, Sabour 813 210, Bhagalpur, Bihar (India) ³Department of Horticulture, DRMLU, Faizabad-224 001, U. P. (India)*

Organic fruit production essentially excludes the use of many inputs associated with modern farming most notably synthetic pesticides and fertilizers. To the maximum extent possible, organic farming systems rely upon crop rotations, crop residues, animal manures, legumes, green manures, off-farm organic wastes, mechanical cultivation, mineral- bearing rock powders and biological pest control. Organic farming is the practice that relies more on using sustainable methods to cultivate crops and it avoids chemical inputs that do not belong to the natural eco system. Organic agriculture can contribute to meaningful socio-economic and ecologically sustainable development, especially in developing countries. These components maintain soil productivity and tilth, supply plant nutrients and help to control insects, weeds and other pests. All factors regarding site suitability for conventional fruit plantings (air and water drainage, etc.) apply even more and so to organic operations. While conventional farmers may fall back on chemical fertilizers and pesticides to compensate for poor site decisions, organic farmers largely give up such luxuries. Environmental constraints (climate, presence of certain pests and diseases, suitable soils, etc.) can greatly impact the suitability of a given site or even a bioregion for organic production of a given fruit crop. Generally speaking, some perennial fruits are easier to grow organically than others. The small fruits (berries) for example, seem easier to grow organically than the tree fruits in almost all locations. Lastly, successful organic fruit growing may depend largely on whether the venture is for home production or for commercial sales.

KEY WORD: Organic, Fruit, Farming, Synthetic Pesticides, Fertilizers etc.

“INSECT PESTS OF STORED PRODUCTS”**ANKIT KUMAR SINGH, RAVI SHANKER, RAVINDRA NATH NISHAD, VIJAY KUMAR, SURYA PRATAP SINGH***Department of Entomology, NDUA&T-Kumarganj, Faizabad (224229) U.P.*

Stored product pests gain access to the grain storage from the standing crop in the field to various stages of grain processing and storage. Although, about one thousand species of insects have been associated with stored products in different parts of the world, a few pests are considered as pests causing severe damage to the stored grains. The stored grain insect pests can be categorized on the basis of their feeding behavior as internal and external feeder or as major and minor pests based on the severity of damage, they cause. The major pests of stored grains viz., rice weevil, *Sitophilus oryzae*, lesser grain borer, *Rhyzopertha dominaca*, khapra beetle, *Trogoderma granarium*, red flour beetle, *Tribolium castaneum*, cigarette beetle, *Lasioderma serricorne*, drug store beetle, *Stegobium paniceum*, pulse beetles *Callosobruchus* spp., Angoumois grain moth, *Sitotroga cerealella*, rice moth *Corcyra cephalonica*, saw toothed grain beetle *Oryzaephilus surinamensis*, long headed flour beetle, *Latheticus oryzae*, and almond moth *Cadra cautella*. External feeders: This group of insects feed on germ and endosperm from outside. These may attack whole seed and damage the germinal portion or feed on the seeds, which have already been damaged/ infested by other insects or broken mechanically. These insect pests or their stages are generally visible among the seeds e.g. rice weevil, pulse beetle, granary weevil, Angoumois moth etc. Internal feeders: These insects

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

mostly lay eggs inside or on the surface of grains, spend a part or entire larval and pupal life inside the grains and only emerge as adults. These contribute significant loss of germination which is not detectable outside e.g. rice weevil, pulse beetle, granary weevil, Angoumois moth etc.

"EFFECT OF MICRO NUTRIENTS ON GROWTH, YIELD AND QUALITY OF CABBAGE (*BRASSICA OLERACEA L. VAR. CAPITATA*)"

ANKIT SHARMA^{*1}, MADAN JHA²

Department Of Horticulture, Faculty Of Agricultural Sciences And Technology Aks University, Sherganj, Satna (M.P), Dept. of Vegetable science, BTC CARS, Bilaspur (C.G.)

The field experiment was conducted during *Rabi* season of 2017-18 at the Horticulture Research farm, AKS university, Satna (M.P.). The experiment was laid out in a randomized block design with three replications. The treatments consisted of eleven combination of different agro input management practices viz., treatments 100%RDF+Fe 0.5% (T₁), 100%RDF+Fe 1.0% (T₂), 100%RDF+Zn 0.5% (T₃), 100%RDF+Zn 1.0% (T₄), 100%RDF+Mn 0.5 % (T₅), 100%RDF+Mn 1.0% (T₆), 100%RDF+B 0.3% (T₇), 100%RDF+ B 0.6% (T₈), 100%RDF+ Fe (0.5%) + Zn (0.5%) + Mn (0.5 %) + B (0.3%) (T₉), 100%RDF+ Fe (1.0%) + Zn (1.0%) + Mn (1.0 %) + B (0.6%) (T₁₀), 100%RDF Control (T₁₁). The maximum net profit/ha was recorded under treatment T₃ (Rs.62,037) while minimum net profit/ha was obtained in treatment T₁₁ (Rs. 40,185). The maximum gross profit/ha was recorded in treatment T₃ (Rs. 1,29,629) whereas, minimum gross profit/ha was recorded in treatment T₁₁ (Rs. 1,05,000). Thus, the maximum income (both gross and net) was obtained with T₃. The significantly maximum B:C ratio 1.93 was recorded under the treatment (T₃). And the minimum B:C ratio 1.62 was recorded under the treatment (T₁₁).

SILICON: A BENEFICIAL ELEMENT FOR FRUIT CROPS

ANKITA AMAN, RUBY RANI, ABHA KUMARI, FEZA AHMAD

Department of Horticulture (Fruit and Fruit Technology), Bihar Agricultural University, Sabour, Bhagalpur-813210, India

Silicon is the second most abundant element in the soil next to oxygen and comprises 28% of its weight. However, still it is not recognized as an essential element for plant growth but the undeniable beneficial effects of this element on the growth and development have been observed in a wide variety of plant species. The role of silicon in plant biology is to reduce multiple stresses including biotic and abiotic stresses. In addition to naturally occurring soluble silicon in soil, many crops respond positively to additions of supplemental silicon. Plants, especially fruit crops, can take up large amounts of silicon where it contributes to their mechanical strength. Besides a structural role, silicon helps to protect plants from insect attack, disease and environmental stress. The highest number of bunches per vine, yield per vine and yield per hectare was observed in Bangalore blue grapes by foliar application of silicic acid and boron. Maximum fruit weight, volume, TSS, sugars to acid ratio and minimum acidity was recorded in guava by the application of RDF +3 kg of DE/plant. Kaolin application showed significantly positive effects on the protection of fruit against sunburn on Hicaznar cultivar of pomegranate. Silicon nutrition enhances host resistance to pests and diseases and also alleviates abiotic stresses thus protecting the crops. In the context of organic farming, the application of siliceous materials and silicon sources to not only agricultural crops but also to horticultural crops especially fruit crops may pave way for increasing the yield and reducing the use of chemical fertilizers, pesticides and fungicides. The ashes from agro industries and industrial slags free from heavy metals will find future source of silicon fertilizers in future to protect the crops and to boost the yield. Despite of this, Si has not received the attention it requires. Hence it is the need of hour to proceed wider and bring together not just strictly plant physiological evidence but to include findings and experiences gathered by botanists, agronomists, horticulturists, plant pathologists, plant biochemists and still others. There is no justification for the disregard of Si in so much science of plant biology. The evidence is forcing that in the real world of plant life, the presence and role of Si matters.

Keywords:- Silicon, beneficial effect, biotic and abiotic stress

EFFECT OF SALINE WATER ON PHYSIOLOGICAL ATTRIBUTES OF RAYAN (*MANILKARA HEXANDRAL*)

ANKITA MANTRI, YATAIN N TANDEL AND J PRATHORE¹

Department of Fruit Science, ASPEE College of Horticulture and Forestry, Navsari Agricultural University, Navsari, Gujarat, Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K)

A field study was carried out at Fruit Research Station, Navsari Agricultural University, Gandevi (Gujarat) during 2017 to find out effect of saline water on physiological attributes of rayan (*Manilkara hexandra* L.). The experiment consisted of six treatments of salinity levels

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

of irrigation water viz., 0.5 dS m⁻¹ (T₁), 2 dS m⁻¹ (T₂), 4 dS m⁻¹ (T₃), 6 dS m⁻¹ (T₄), 8 dS m⁻¹ (T₅) and 10 dS m⁻¹ (T₆). It was laid out in a completely randomized design (CRD) with three repetitions. The observations on photosynthetic parameters were recorded. The results indicated that all physiological parameters were decreased with increasing salinity levels. Photosynthetic parameters viz., photosynthetic rate (26.14, 27.31 and 29.79 $\mu\text{mol CO}_2\text{m}^{-2}\text{s}^{-1}$, respectively), stomatal conductance (0.036, 0.061 and 0.066 $\text{mmol CO}_2\text{m}^{-2}\text{s}^{-1}$) and transpiration rate (0.54, 0.57 and 0.623 $\text{mmol H}_2\text{O m}^{-2}\text{s}^{-1}$) were recorded the highest in treatment T₁ (0.5 dS m⁻¹) at 40, 80 and 120 days after treatment. Whereas the lowest photosynthetic parameters were noted in the treatment T₆ (10 dS m⁻¹). The treatment T₁ (0.5 dS m⁻¹) showed higher relative water content RWC (86.25 %) in rayan seedlings. The minimum RWC (%) was recorded in treatment T₆ (10 dS m⁻¹). It is therefore, inferred from the present study that rayan seedlings can grow well upto 8 dS m⁻¹ salinity level with optimum physiological parameters in seedlings can get upto 4 dS m⁻¹ salinity level.

RECENT TRENDS IN AGRICULTURAL SCIENCES AND TECHNOLOGY

SUB THEME - INTEGRATED NUTRIENT, WEED, DISEASES AND PEST MANAGEMENT

ANKUR BHAKAR*

Department of Agronomy, NDRI, Karnal (Haryana), India

Agricultural production in the country has been increasing to great heights since green revolution. Development of new varieties, fertilizer application and use of pesticides to control the crop pests helped to increase production. But the negative side is that loss of rich biodiversity, soil health, pesticide residue in consumable agricultural products, higher cost of production and also excessive reliance on the chemical pest control leads to pest resurgence and resistance. For nutrient application farmer should use the organic and inorganic easily available nutrient sources in a complimentary manner with right type and right dose, at the right time, right place and by right method to sustain and enrich the soil health. For weed, disease and pest control the aim should be control of all these pest to the economic threshold level, as it will be economic for the farmer and safer for the biodiversity too. For controlling the pests the cultural, mechanical, biological, Quarantine and chemical measures should be followed in an integrated manner. Cultural measures include crop rotation, land rotation, inter and mixed cropping of cereal, legume, stale seed bed technique, deep ploughing in summer, use of resistant varieties, etc. Mechanical measures include mowing, dredging and churning, use of light, bait and pheromone traps, etc. Biological measure include use of predators, parasitoids, bioherbicides, etc. Quarantine measure means non allowance of the infested seed and plant samples to export from one area to another within same or different countries. Chemical control includes use of herbicides, fungicides, insecticide, etc at the right dose. So all these measure should be used integratedly by the farmer to maintain sustainability.

Keywords Production, biodiversity, complimentary, quarantine, sustainability

HIGH PRESSURE PROCESSING OF FOODS

ANKUR MAHENDRA ARYA*, TARUN KUMAR, VAISHALI, KAVINDRA SINGH, VIPUL CHAUDHARY

Department of Agricultural Engineering, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut (UP) 250210 India.

HPP subjects liquid or solid foods, with or without packaging to pressures between 100 and 800 MPa (14,500 to 116,000 PSI). Process temperature during pressure treatment can be specified below 0°C to above 100°C. Commercial exposure times can vary from a millisecond pulse to over 20 minutes. HPP acts instantaneously and uniformly through a mass of food independent of size, shape and food composition. Thus package size, shape and composition are not factors when determining the process. The work of compression will increase the temperature of the foods by approximately 3°C per 100 MPa, depending on the composition of the food. If a food contains a significant amount of fat the temperature rise can be larger. Foods cool down to their original temperature on decompression if no heat is lost or gained from the vessel walls of the chamber during the hold time at pressure. As pH is lowered most microbes become susceptible to HPP inactivation and sub lethally injured cells fail to repair. Acid foods suggests that shelf-stable (commercially sterile) products, having a water activity close to one, and pH values less than 4.0, can be preserved using a pressure of 580 MPa and a process hold time of 3 min. Acid foods between the pH values of 4.0 and 4.5 can be made commercially sterile using a pressure of 580 MPa and a hold time of 15 min. Products would have an initial temperature in the range of 22°C. Reducing water activity appears to protect microbes against inactivation by HPP. Temperatures in the range of 45 to 50 °C appear to increase the rate of inactivation of food pathogens and spoilage microbes and thus warrant the development of processes which incorporate a uniform initial food temperature in this range. Process temperatures in the range of 90-110 °C in conjunction with pressures of 500-700 MPa have been used to inactivate spore forming bacteria such as *Clostridium botulinum*.

Keywords: HPP technology, Temperature, pH, Water activity (aw)

“EFFICACY OF BIO-INSECTICIDES AND BOTANICALS AGAINST BRINJAL SHOOT AND FRUIT BORER (*LEUCINODES ORBONALIS* GUENEE)”**ANKUR PRAKASH VERMA AND UMESH CHANDRA (DEPT. OF ENTOMOLOGY)***N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P)*

The present investigation was carried out during the *Kharif* season, 2017-18 at Student's Instructional Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P) to study the efficacy of bio-insecticides and botanicals against brinjal shoot and fruit borer (*Leucinodes orbonalis* Guenee). The bio-insecticides and botanicals tested were: Emamectin benzoate 5 SG @ 75 g a.i./ha, Spinosad 45 SL @ 18 g a.i./ha, NSKE 5 %, Karanj seed extract 5 %, Onion extract 5 %, Garlic extract 5 %, Tobacco extract 5 %, Cannabis (bhang) leaf extract 5 %, Wood ash 10 g/plant and compared with control. Results showed that Emamectin benzoate 5 SG (75 g a.i./ha) treated plots showed lowest infestation and gave higher fruit yield (313.85 q/ha) followed by Spinosad 45 SL (18 g a.i./ha) and NSKE (5%) which gave 300.58 and 284.33 q/ha fruit yield respectively. The least effective treatment was Wood ash (10 g/plant) and yielded only 225.14 q/ha healthy fruits. This study recommends the use of bio-insecticides and botanicals as they are significantly efficient in managing the brinjal shoot and fruit borer infestation.

Key words: Bio-insecticides, Botanicals, Brinjal shoot and fruit borer, *Leucinodes orbonalis*

“RESPONSE OF BORON LEVELS AND APPLICATIONS METHODS ON GROWTH AND YIELD OF RICE (*ORYZA SATIVA* L.)”**ANKUR SHUKLA AND SATYBHAN SINGH***School of Agricultural Sciences and Engineering, IFTM University, Moradabad-244102*

The experiment was laid out at research farm of Department of Soil which entitled impact of Response of Boron levels and application methods on growth and yield of Rice (*Oryza sativa* L.) in north- western plain zone of India was carried out at School of Agricultural Science and Engineering, IFTM University, Moradabad in 2017-18. Boron carries out certain important function in plants like it helps in cell wall formation, stabilization and lignifications; encourage pollen tube growth and pollen germination in grain crops. The experiment was laid out in Randomized Block Design with 10 treatments and 3 replication. These are details of treatments were $T_1 = 100\% \text{ RDF (150 : 60 : 40 kg ha}^{-1}\text{)}$; $T_2 = 100\% \text{ RDF} + 0.5 \text{ kg B ha}^{-1} \text{ (SA)}$; $T_3 = 100\% \text{ RDF} + 0.5 \text{ kg B ha}^{-1} \text{ (SA)} + 0.2\% \text{ B spray at 25 \& 50 DAT}$; $T_4 = 100\% \text{ RDF} + 0.5 \text{ kg B ha}^{-1} \text{ (SA)} + 0.3\% \text{ B spray at 25 \& 50 DAT}$; $T_5 = 100\% \text{ RDF} + 1.0 \text{ kg B ha}^{-1} \text{ (SA)}$; $T_6 = 100\% \text{ RDF} + 1.0 \text{ kg B ha}^{-1} \text{ (SA)} + 0.2\% \text{ B spray at 25 \& 50 DAT}$; $T_7 = 100\% \text{ RDF} + 1.0 \text{ kg B ha}^{-1} \text{ (SA)} + 0.3\% \text{ B spray at 25 \& 50 DAT}$; $T_8 = 100\% \text{ RDF} + 2.0 \text{ kg B ha}^{-1}$; $T_9 = 100\% \text{ RDF} + 2.0 \text{ kg B ha}^{-1} \text{ (SA)} + 0.2\% \text{ B spray at 25 \& 50 DAT}$; $T_{10} = 100\% \text{ RDF} + 2.0 \text{ kg B ha}^{-1} \text{ (SA)} + 0.3\% \text{ B spray at 25 \& 50 DAT}$. Application of boron also markedly increases yield and quality of oil seed crops. The literature on the significance of Boron in growth as well as physiological functions of pulses and oil seed crops have been reviewed and presented.

NOVEL DIAGNOSTIC TECHNIQUES FOR DISEASE DETECTION IN PLANTS.**ANNIE KHANNA^{1*}, KUSHAL RAJ¹ AND MEENAKSHI RATHI²***Department of Plant Pathology¹ and Department of Genetics and Plant Breeding², College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar 125004, Haryana, India*

Automatic methods for an early detection and diagnosis of plant diseases are vital for crop protection and management. Detection and diagnosis of the disease is the foremost requirement for managing the plant disease. Appropriate identification of pathogen viz., fungi, bacteria, viruses includes techniques like immunodiagnosis, monoclonal antibodies, which often manifests no disease symptoms. The major drawback with these techniques is that they are efficient under laboratory conditions, time consuming and labour intensive nature. In the era of robotics there is a need of new rapid and innovative technologies like electronic nose, hyperspectral imaging that provides proper identification, detection and accurate quantification of plant pathogenic microorganisms at site itself. Non destructive methods like spectroscopic, imaging techniques or volatile compound based techniques have been developed in the last few decades. In today's scenario chlorophyll fluorescence, hyperspectral sensors and thermography permit fast diagnosis in field itself because of its speed, simplicity and robustness and thus fulfils the basic requirement of proper disease management. Electronic nose also known as E-nose is an instrument that detects and discriminate among complex odours by means of a sensor array planned and developed to respond against various volatile organic compounds. It is being used for bacterial disease diagnosis and those concerning analytical tools such as gas chromatography (GC) or GC coupled with mass spectrometry for headspace analysis. The ability of E-nose to discriminate healthy potato tubers from those infected by *Ralstonia solanacearum* and *Clavibacter michiganensis* subsp. *sepedonicus* with a percentage of accuracy of 100% and 70%, respectively.

PINEAPPLE DISEASE OF SUGARCANE: CURRENT STATUS AND FUTURE PROSPECTS**ANNIE KHANNA*, KUSHAL RAJ AND POOJA SANGWAN***Department of Plant Pathology, College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar 125004, Haryana, India*

Pineapple disease caused by *Ceantosystis paradoxa* [Dade.] Moreau is the major disease of sugarcane (*Saccharum officinarum*) causing substantial yield and economic losses. Keeping in view the economic importance of the disease, various management strategies like use of fungicides, botanicals, biocontrol agents can be used. For the effective management systemic fungicides were found to be more effective than non systemic. In the recent years botanicals viz., *A. sativum*, *Z. officinale* and *A. indica* were found effective in managing the disease. Worldwide efforts have been to find out the resistant sources to develop resistant varieties but due to highly variable nature of *C. paradoxa*, exploitation of host resistant has remained a challenging job for breeders as well as pathologists. Still scientists are doing their best to develop the resistant varieties. Among biocontrol agents strains of *Trichoderma* sp. and *Pseudomonas* are in use. The availability of genome of pathogen *C. paradoxa* and sugarcane can open new door for isolation and characterization of R and Avr gene, development of noble fungicides, transgenic sugarcane crop etc.

WEAR STUDIES IN AGRICULTURAL IMPLEMENTS: A REVIEW**ANNU RANI, T. P. SINGH***G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand, India 263145*

Agricultural machinery and equipment used for soil cultivation are exposed to continuous wear and tear. Tough and challenging field work leads to abrasion wear of machinery. A major portion this wear loss in agricultural implements is attributed to the movement of tools in soil. During ploughing action, farm implements face abrasive action of sand and stone particles present in the soil. This is the most common cause of damage of agricultural machinery. Worn out agricultural tools results in poor tillage and seeding efficiency and higher fuel costs. Farmers continuously face problems with recurring labour, downtime and the replacement costs of exchanging the worn out tools. Use of heavier implements in modern agriculture increases the demand for wear resisting methods. Hard facing of the tillage tools and coating of the hard material on the agricultural implements are the widely applied methods to reduce the abrasive wear. Coating deposits a layer of hard material over the base tillage material and improves its wear and corrosion resistance properties. This increases the life of the agricultural machines and saves time and of farmers. This paper presents a thorough review on wear determining studies done in the field of agriculture and discusses the different methods to reduce the wear.

SALT AFFECTED SOILS IN INDIA AND THEIR MANAGEMENT STRATEGIES**ANOOP KUMAR DEVEDEE*, SINGH R.K.¹, VISHAL KUMAR¹, DHARMINDER¹ AND MANISH KUMAR SINGH²***Department of Agronomy, Institute of Agricultural Sciences, BHU, Varanasi, 221005, UP, Department of Horticulture, Institute of Agricultural Sciences, BHU, Varanasi, 221005, UP*

Globally, 75 countries have been recognized as having vast areas of salt-affected lands. Martinez-Beltran and estimated that nearly 831 million hectares of land are salt-affected worldwide. Salt-affected soils mostly exist in arid and semiarid regions of the world, and many salt affected waste lands have been productive lands in the past. Worldwide, about 95 million hectares of soils are under primary salinization (salt accumulation through natural processes in soils and water) whereas 77 million hectares suffer from secondary salinization (as a result of human activities and ever-rising groundwater). Of major concern is that 23 % of the arable lands in the world is affected by salinity and a further 10 % are saline sodic soils while 340 million hectares of lands suffer sodality. The high salt concentration negatively affects soil microbial activity as well as soil chemical and physical properties, thus causing a decline in soil productivity. Decline in vegetation growth due to salt toxicity and detrimental osmotic potential results in lower carbon inputs into these soils and further deterioration of their physical and chemical properties. Accumulation of excess salts in the root zone resulting in a partial or complete loss of soil productivity is a worldwide phenomenon. The problems of soil salinity are most widespread in the arid and semi-arid regions but salt affected soils also may occur extensively in sub-humid and humid climates, particularly in the coastal regions where the ingress of sea water through estuaries and rivers and through groundwater causes large-scale salinization. Soil salinity is also a serious problem in areas where groundwater of high salt content is used for irrigation (Singh and Bhumla, 1998) and the process is known as secondary salinization. The most serious salinity problems are being faced in the irrigated arid and semi-arid regions of the world and it is in these very regions that irrigation is essential to increase agricultural production to satisfy food requirements. However, irrigation is often costly, technically complex and requires skilled management. Failure to apply efficient principles of water management may result in wastage of water through seepage; over-watering and inadequate drainage result in water logging and salinity problems which reduce the soil productivity, eventually leading to loss of cultivable land.

COMPARATIVE EFFECT OF SOIL SOLARIZATION, NEEM CAKE AND GREEN MANURING AGAINST *ALTERNARIA BRASSICAE* ON CABBAGE (BRASSICA OLERACEA L. VAR. CAPITATA)**ANOOP KUMAR, VEDPRAKASH SANODIYA, AMIT KUMAR MAURYA AND VINNY JOHN***Department of plant protection, SHUATS Allahabad (211007)*

An experiment was conducted to evaluate comparative effect of soil solarization, Neem cake and green manuring against *Alternaria brassicae* on cabbage. Soil solarization was done in the month of May - June 2012, green manuring was done in the month of September and neem cake was applied in the month of October before 7 days of transplanting. The most effective treatment was T5 neem cake which significantly reduced disease intensity (20.65 %) followed by treatments T4 soil solarization (24.3 %), T2 cowpea (26.0 %), T1 dhaincha (28.07 %), T3 sudan grass (28.3 %) and including T0 control (32.52 %). Maximum yield 285.02 q/ha was recorded neem cake treatment followed by sudan grass 262.2 q/ha, dhaincha 259.22 q/ha, soil solarization 243.52 q/ha, cowpea 234.25q/ha and including control 147.92q/ha. The highest cost benefit ratio was obtained in T5 neem cake (1:3.1.3) followed by T1 dhaincha (1:3.09) as compared with other treatments including control. Neem cake was found significantly superior over other treatments.

Key words :- *Alternaria* blight, Cabbage, Cowpea, Dhaincha, Green manure, Neem cake, Soil solarization and Sudan grass.

AGRIPRENUERSHIP WAY TO UPLIFTMENT OF AGRICULTURE**ANSHIKA CHAUHAN, GIRISH TIWARI***Department Of Agriculture, Shri Guru Ram Rai University, Dehradun, Uttarakhand-248001*

Agripreneurship is the profitable marriage of agriculture and entrepreneurship. Agripreneurship turn your farm into an agribusiness. The term Agripreneurship is synonym with entrepreneurship in agriculture and refers to agribusiness establishment in agriculture and allied sector. Agripreneurship have the potential to contribute to a range of social and economic development such as employment generation, income generation, poverty reduction and improvements in nutrition, health and overall food security in the national economy. Agripreneurship plays various roles in the growth and development of national economy. It helps in inducing productivity gains by smallholder farmers and integrating them into local, national and international markets. It helps in reducing food costs, supply uncertainties and improving the diets of the rural and urban poor in the country Agripreneurship is the need of hours to make agriculture a more attractive and profitable venture. It is clear that there is a great scope for entrepreneurship in agriculture and this potentiality can be tapped only by effective management of agriculture elements such as soil, seed, water and market needs.

APPLICATION OF E-TECHNOLOGY IN MODERN AGRICULTURE: PRESENT SCENARIO IN INDIA**ANUJANWALA^{1*} AND MANOHER SARYAM¹***Department of Extension Education, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi (UP) 221005*

E- technology has the potential to help agriculture produce higher-yielding, better-quality crops for lower cost. Collecting and interpreting data from soil, crops and the environment can help farmers understand issues from how to tackle disease and pests to when to water or fertilize fields by sensing, combining and analyzing new data, the industry can potentially see problems coming and take action early cutting costs and lowering the risk of ruined crops. E-Agriculture is a new area of knowledge emerging out of convergence of IT and farming techniques. It enhances the agricultural value chain through the application of internet and related technologies. Basically IT helps farmers to have better access to information which increases the productivity. It also enables him to get better prices through information of change in price in different markets. Agriculture in India is the core sector for food security' nutritional security' and sustainable development for poverty alleviation. It contributes approx. 14 percent of GDP. Milestones in agriculture development in India includes: Green revolution' Evergreen revolution' Blue revolution' white revolution' yellow revolution' Bio technology revolution and the most recent one is Information and communication technology revolution E-technology supports new methods for precision agriculture like computerized farm machinery that applies for fertilizers and pesticides. Farm animals are fed and monitored by electronic sensors and identification systems. Selling or buying online began to become popular in the world. However, its most important role remains communication, and the internet has provided us with an ideal opportunity to do so.

Keyword- E-technology, agriculture, information-technology, development, ICTs etc.

POTASSIUM TRANSFORMATION IN RELATION TO SOIL PLANT SYSTEMS**ANUPAM ADARSH¹, ARVIND BHAI PATEL² TEJ PRATAP³ HANUMANT SINGH⁴**

¹Department of Horticulture (Vegetable & Floriculture) and ^{2,3}Department of Agronomy, Bihar Agricultural University, Sabour (Bhagalpur) 813 210, Bihar. ⁴Department of soil and land use survey of Ahmadabad, Gujarat.

Potassium is an essential nutrient for all plants. It plays an important role in maintaining water regime and activation of various enzymes

in plants. The potassium content in mineral soils is generally much higher than that of the other macronutrients like nitrogen and phosphorus. The concentration of potassium in soil solution varies from soil to soil depending on the parent rock, mineral matter and climatic conditions. The mica and feldspars constitute the major potassium bearing minerals which on weathering, gradually release potassium to the soil. Generally four forms of potassium present in soils namely solution, exchangeable, non-exchangeable and reserve of mineral potassium. A large portion of total potassium in soil comes from the potassium bearing and crystal lattices of silicate minerals. Mobility of potassium in soils produces dynamic equilibria among various forms of potassium. Exchangeable and soil solution potassium equilibrate quickly while difficulty or fixed form of potassium equilibrates very slowly with its exchangeable and soil solution forms. Release of potassium from the reserve or mineral forms of potassium to any other there forms of potassium is extremely slow and hence it is strictly considered unavailable form of potassium to plants particularly in a single cropping season. Fixed or non-exchangeable potassium occurs within clay minerals such as illite, vermiculite and chlorite. On the contrary, exchangeable potassium is held on soil colloids by electrostatic forces which facilitate the release of potassium into the soil solution rendering available to plants. Therefore, there is a continuous slow transfer of potassium from the mineral source to the exchangeable and slowly available forms.

EFFECTS OF "BIOPRIMING" ON RICE SEED GERMINATION AND BAKANAE DISEASE (*FUSARIUM MONILIFORME*) OF RICE.

ANUPAM KUMAR, KAMAL KHILARI, JASKARAN SINGH, SATPAL SINGH, ABHISHEK KUMAR AND JAI PRAKASH KANNAUJIA

Department of Plant Pathology, SVPUA&T, Meerut, UP, India.

Rice (*Oriza sativa* L.) is the food of more than 60 % of the world's population. It is staple food of most of the people of south-eastern Asia. India is the second largest producer and consumer of rice in the world after China. Rice crop production is affected by several abiotic and biotic factors among the biotic factor bakanae disease one of the most serious problem of rice. *Fusarium moniliforme* produced different kind of symptoms on rice seed and seedling like: abnormal elongation of seedlings and foot rot etc. This disease cause 20% to 50% yield losses in Japan, 15% in India and 3.7 % in Thailand. Under favorable conditions, it may cause substantial damage, and as high as 95.40 % yield loss. In the advance stage of the disease, rotting was observed at the base of infected plant and infected plants die. Some of the infected plants survive up to maturity of the crop. Seed treatment with biocontrol agents along with priming agents may serve as an important means of managing many of the soil and seed borne diseases, the process often known as "biopriming". Seed priming is now a widely used commercial process that accelerates the germination rate and improves seedling uniformity in many crops. The minimum 8.93 and 14.48 % disease incidence were recorded in T₃ (Multani soil + *Trichoderma* + *Propiconazol* + *Molasses*) and maximum disease incidence 26.85 and 27.14 % were recorded in T₅ (Multani soil + *Trichoderma*) at 15 and 30 DAS respectively. Viability of *Trichoderma* maximum viability 326.677×10^4 cfu/gm was recorded in T₆ (Multani soil + *Trichoderma*) and maximum 252.33×10^4 cfu/gm was recorded in T₆ (Multani soil + *Trichoderma*) after 1 day incubation, the maximum 144×10^4 cfu/gm was recorded in T₆ (Multani soil + *Trichoderma*) and maximum 271.33×10^4 cfu/gm was recorded in T₅ (Multani soil + *Trichoderma* + *Neem Cake*) after 3 days incubation and the maximum 255×10^4 cfu/gm was recorded in T₄ (Multani soil + *Trichoderma* + *Molasses*) while maximum 38.67×10^4 cfu/gm was recorded in T₅ (Multani soil + *Trichoderma* + *Neem cake*) after 6 days incubation at room temperature and refrigerator temperature respectively.

DETECTION AND DIAGNOSIS OF PLANT VIRUSES

ANUPAM KUMAR, KAMAL KHILARI, SATPAL SINGH, AMIT KUMAR YADAV, AJAY KUMAR MISHRA RAMPAL VERMA, SURANDRA KUMAR AND SONU KATIYAR

Department of Plant Pathology, SVPUA&T, Meerut, UP, India.

Plant viruses cause major losses to several agricultural and horticultural crops around the world. Unlike other plant pathogens, there are no direct methods available, yet to control viruses, consequently, the current measures rely on indirect tactics to manage the viral diseases. Methods for correct & quick detection and identification of viruses, both in plants and vectors play a critical role in virus disease management. Diagnostic techniques for viruses fall into two broad categories: biological properties related to the interaction of the virus with its host and/or vector (e.g. symptomology and transmission tests) and intrinsic properties of the virus itself (coat protein and nucleic acid). Detection methods based on the coat protein include precipitation/agglutination tests rely on the formation of a visible precipitate, Enzyme Linked Immunosorbent Assay (ELISA) has been very popular for detection of viruses in plant material, insect vectors, seeds and vegetative propagules. And immunoblotting can be used to detect viruses in both plants and vectors. Viral nucleic acid based techniques like polymerase chain reaction (PCR) is an *in-vitro* method for amplifying target nucleic acid sequences and more sensitive than other methods. Availability of these diagnostic methods provide greater facility with increased sensitivity and specificity for rapid diagnosis of virus diseases and epidemiological studies, plant quarantine and seed certification and breeding programmes also greatly benefitted with these techniques.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**PLASMA AGRICULTURE: A NEW TECHNIQUE IN AGRICULTURE****ANUPAMA RAWAT*, RAJEEW KUMAR, VIJAY PALSINGH, BANDANA BHATT***Department of Agronomy, College of Agriculture, Govind Ballabh Pant University of Agriculture and Technology*

Agriculture across the globe is running out of natural resources with shortage of land and increasing population. In order to sustain the system and protect environment, the only way left is to adopt new technologies which are sustainable, economical and socially acceptable. Plasma agriculture is one of those technologies. Plasma is the fourth, a least known state of matter. Plasma is the mixture of positive and negative charges as well as neutral particles. It exists a massive range in temperatures and densities. The low temperature plasma (LTP) can be used in seed germination, seed disinfection, sterilization, growth increasing crop yield. Plasma treated seeds show enhanced germination demanding less input like chemical fertilizers and water. Plasma treated seeds imbibe more water increasing germination rate. With enhanced germination this approach gives initial uniform plant stand. The seeds are exposed to charged particles bombardments resulting in formation of functional groups on the treated surface. The plasma treated seeds could have variety of effects on morphological and sowing characteristics due to the complexity of plasma interaction with living cells and organic molecules. Plasma treated seeds shows no chromosome damage. Industrial production of plasma treated seeds can be done long before planting time as delay between plasma treatment and germination still give favorable results.

Key words: Plasma, sustainable, germination

AEROBIC RICE, A NEW APPROACH OF RICE CULTIVATION IN CLIMATE VARIABILITY AND UNCERTAINTY**ANUPMA KUMARI***Krishi Vigyan Kendra, Saraiya, Muzaffarpur*

Climate variability and uncertainty resulting in the shortage of water resource has led to the development and adoption of aerobic rice system which saves water input and increases water productivity by reducing water use during land preparation and limiting seepage, percolation and evaporation. In the past several years, the water situation in the growing area faces water shortage and rice cultivation has been challenged for near future. Due to these reasons, farmers are seeking alternate crops that require lesser water. The prediction is that the rice production in future could be drastically reduced. In an aerobic rice system, the crops are directly seeded and soil is kept aerobic throughout the growing season. Supplemental irrigation is applied as necessary. Grain yield of 5-6 t/ha can be reached in aerobic rice system. However, yield decline or even complete failure of rice under continuous monocropping threatens the widespread adoption of aerobic rice system. Here we review research findings on possible causes responsible for yield decline which are biotic and abiotic factors, selection of new aerobic rice cultivars, nutrient management and crop rotation. Identifying the causes responsible for continuous cropping obstacle of aerobic rice and adopting effective strategies are crucial to achieve sustainability of aerobic rice.

EFFECT OF KONKAN ANNAPURNA BRIQUETTES AND ORGANIC MANURES ON GROWTH AND YIELD OF SWEET POTATO**ANURADHAA. HARMALKAR*, S.B. DODAKE, M.C. KASTURE AND HARI RANE***Department of Soil Science and Agricultural Chemistry, College of Agriculture, Dapoli, Dist. Ratnagiri, Maharashtra*

A field experiment conducted during Rabi 2016 entitled, "Effect of Konkana Annapurna Briquettes and organic manures on yield and quality of sweet potato" at Central Experiment station, Wakawali. The experiment was laid out in Factorial Randomized Block Design (FRBD) comprising twelve treatment combinations replicated thrice and observations were recorded at 35, 70 and after harvest. The effect of different inorganic fertilizers and organic manures viz., Konkana Annapurna Briquettes, straight fertilizers, FYM and vermicompost either alone or in combinations on growth and yield were studied. The growth and yield parameters showed significant improvement as a consequence of various treatment combinations. It was observed that 75% RDN through Konkana Annapurna Briquettes (KAB), which was, applied 7 briquettes per 10 plants after one month of planting along with vermicompost @ 5 t ha⁻¹ prior to planting, which found promising to enhance the tuber yield, plant height, tuber length, number of tubers per vine.

Keywords: Konkana Annapurna Briquettes, organic manures, growth, yield.

ROLE PERFORMANCE OF RURAL WOMEN IN ANIMAL HUSBANDRY PRACTICES**(ANURADHARANJAN KUMARI¹, A K SINGH², M. K. PANDEY³, KAMLESH MEENA⁴ AND AJAY TIWARI⁵)**

SMS, Home Science, Krishi Vigyan Kendra (ICAR-IIVR) Deoria UP, SMS, Animal Science, Krishi Vigyan Kendra (ICAR-IIVR) Deoria UP, SMS, Plant Pathology, Krishi Vigyan Kendra (ICAR-IIVR) Deoria UP, SMS, Agronomy, Krishi Vigyan Kendra (ICAR-IIVR) Deoria UP, Farm Manager, Krishi Vigyan Kendra (ICAR-IIVR) Deoria UP.

Women play a significant role in dairy farming but their control over livestock and its products is very minimal. The income incurred

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

from dairy animals neither remains in hands of women nor the decision making regarding sale and purchase of the various items required in a dairy unit. The study was carried out to know the participation of rural women in dairy activities of Deoria district of U.P state. The study was carried out in two blocks i.e. Salempur and Bhatparrani families owning two to three cattle heads were selected for this study. A sample of sixty families was selected randomly from each block, thus the total sample comprised of 120 families. One female member shouldering the responsibilities in dairy management from each family represented the study sample. The data were collected personally with the help of structured interview schedule. Data collected were statistically analyzed with the help of frequency and percentages. The data revealed that the participation of women was high in activities such as Cleaning of cattle shed, watering, feeding, milking, disposal of cow dung. The farm women participation was least in dairy related record maintenance, getting loans or credits from the banks, taking animals for grazing, fodder collection and harvesting the fodder crops. Thus there is need to educate them about scientific management practices for increasing livestock production.

BIOLOGICAL CONTROL OF DISEASE IN VEGETABLE CROPS: A SUSTAINABLE TOOL

ANURADHASINHA

Bihar Agricultural College, Bau, Sabour, Bhagalpur, Bihar

Integrated disease management (IDM) programme implies all the available disease management approaches including cultural, biological and chemical control with the main objective to keep the disease incidence below economic threshold level. One of the major components of integrated disease management is biological control. Biological control is the utilization of any living organism for the control of insect, pest, disease, nematode and weeds. Adoption of biological control against the diseases encountered in vegetable crops is very important as most of the vegetable crops are consumed raw as salad and also cooked with other ingredients and in most of the crops, products are not harvested only at the end of the crop season but it is spread over a long duration by way of several pickings, as in case of tomato, brinjal, okra, cucurbits, pea, beans, etc. Under this measure, biological agent i.e. fungus, bacteria and virus are exploited to control diseases. *Rhizoctonia* sp., *Fusarium* sp., *Pythium* sp., *Macrophomina* sp., *Ralstonia* sp. and *Meloidogyne* sp. in tomato, brinjal, pea, cucumber, controlled by using of *Trichoderma* sp., *Pseudomonas* sp. and *Bacillus* sp. Root rot, wilt and collar rot disease are also managed by *Trichoderma* sp. *Aspergillus niger* has been proved effective against *Fusarium* sp. These bioagents are effectively used either by seed treatment or soil application. By keeping in view of long residual effect of applied chemicals, it becomes imperative to concentrate alternate methods of diseases control without the negative impact of chemicals on agro-ecology, effective utilization of biological control of disease is very important for ecologically sound integrated disease management strategies.

Key Word: Integrated Disease Management, Vegetable Crops, Biocontrol Agents

DIRECT SEEDED RICE: STRATEGIC RESEARCH AND EMERGING ISSUES IN INDIA

ANURAG KUMAR SINGH¹, TEJBAL SINGH¹, UDAY PRATAP SINGH², BRIJESH KUMAR CHAUDHARY¹

Department of Agronomy, Banaras Hindu University, India, Department of Plant Physiology, Banaras Hindu University, India

In India, Rice production is most important part of the national economy. India is second largest producers of rice after China, accounting for 20% of all world rice production. Transplanting is the most common method for obtaining good economic yields in rice cultivation. It requires operations like nursery raising and its management, pulling out of seedlings, transporting and distributing them to the main field for transplanting that amounts about 30-40 per cent of the total cost of cultivation (Chaudhary and Varshney, 2003). Change in rice establishment method from traditional manual transplanting of seedlings to DSR has occurred in many Asian countries in the last two decades in response to rising production costs, especially for labour and water (Pandey and Velasco 2002; Chauhan and Johnson, 2009). By 2025, it is expected that 'economic water scarcity' is bound to affect most of Asia's (22 m ha) irrigated and dry-season rice (Tuong and Bouman, 2003). With such constraints, increasing the production of rice in the future to feed increasing population is a great challenge. DSR has various methods which consume much lesser amount of water i.e.; wet-seeded rice (941.5 ha mm) and dry seeded rice (915.0 ha mm) than transplanting (1041.2 ha mm) (Bhuiyan et al., 1995; Thakura et al., 2004). In this way it reduces cost of cultivation by minimizing labour cost (reduces labour requirement as much as 50 percent than transplanting) and irrigation cost also.

Key words: national economy, economic water scarcity, wet-seeded rice.

PROBABILITY ANALYSIS FOR PREDICTION OF ANNUAL MAXIMUM RAINFALL OF ONE TO FIVE CONSECUTIVE MONTHS FOR SULTANPUR REGION, UTTAR PRADESH**ANURAG PATEL¹, RAJKUMAR VERMA² AND SUSHEEL KUMAR PATEL³**^{1,2,3}*Vaugh School of Agricultural Engineering and Technology, SHUATS, Allahabad (U.P.) 211007*

The present study was conducted for probability analysis of previous 17th years (1994-2010) with the prime objective for prediction of annual maximum rainfall (145.00, 239.06, 302.74, 424.5, and 483.3) of one to five consecutive months of Sultanpur region. The maximum rainfall values were estimated by proposed prediction models viz. Gumbel, Log Pearson Type III and Log Normal. The predicted and observed values were also established. The rainfall data has been in the above distributions and their corresponding rainfall events were estimated at 5.5, 11.5, 16.6, 33.3 and 50 percent probabilities level. The goodness of fit models was tested by Chi-square formula proposed by Hogg and Tanis. The comparison between the measured and predicted maximum value of rainfall clearly shows that the developed model can be efficiently used for the prediction of rainfall. The statistical comparison by Chi-square test for goodness of fit clearly indicates that the Gumbel distribution was found to be best model for predicting two, three, four and five consecutive month's annual maximum rainfall. While Log Pearson types III are fairly close to observed for one and four consecutive month's annual maximum rainfall. The rainfall prediction by Log Normal distribution shows very close relation to the observed rainfall for one consecutive month's annual maximum rainfall (mm).

Keywords: Log Pearson Type III Log, Prime objective, Chi-square test, Sultanpur and Rainfall

DEVELOPMENT AND TESTING OF TRACTOR OPERATED VARIABLE DEPTH FERTILIZER APPLICATOR ON APPLICATION OF GRANULAR UREA IN WHEAT CROP (TRITICUM AESTIVUM) PLANTED ON BEDS.**ANURAG PATEL,²R.C. SINGH,²DUSHYANT SINGH,¹ASHOK TRIPATHI¹S.C. MOSES AND²PRABHAKAR SHUKLA***Vaugh School of Agricultural Engineering and Technology, SHUATS, Allahabad (U.P.) - 211007, Central Institute of Agricultural Engineering, Bhopal (M.P.) 462038*

High fertilizer rate and labor requirement are common problems in traditional application of fertilizer. Fertilizer applicator was tested and evaluated for wheat crop (*Triticum aestivum*) planted on bed cultivation system. Study included suitable measurement techniques for recording various field parameters. Physical properties of granular urea fertilizer have been studied such as size and shape, sphericity, moisture content (18.7 %), bulk density (0.76 g/m³) and hundred particles weight (0.8 gm). The machine was calibrated in the laboratory for different rate of fertilizer application and determination of coefficient of variation. The field tests of machine were conducted on the wheat crop planted on bed in 5 rows. Operating parameters such as operational speed (3.7 km/h), wheel slippage (4.69 %), average field capacity (0.65 ha/h), field efficiency (80.10 %) and plant damage (4.33 %) were found respectively. Crop and Straw yield 5.72 t/ha, 5.38 t/ha, 6.1 t/ha and 15.82 t/ha, 15.89 t/ha, 16.5 t/ha, were found for three fertilizer application methods broadcast, foliar application and tractor operated fertilizer applicator. The tractor operated variable depth fertilizer applicator resulted 3 % and 6.5 % increase in yield as compared to broadcast and foliar application. Because in this method ammonia did not evaporate to the atmosphere due to placing of fertilizer at a depth of 100 mm below the soil surface. The saving of fertilizer by placing it in the soil by tractor operated fertilizer applicator was 33.33 and 16.6 kg/ha as compared to broadcast and foliar methods, which leads to saving of Rs 341 and Rs 611/ha respectively.

Keywords: Wheat crop, Tractor operated, Fertilizer applicator, Broadcast and foliar application

CONSERVATION AGRICULTURE: A WAY FORWARD FOR NATURAL RESOURCE MANAGEMENT AND SUSTAINABLE AGRICULTURE**ANURAG UPADHYAY***Department of Agronomy, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi, 221005*

Conservation agriculture (CA) technologies involve minimum soil disturbance, permanent need based soil cover through crop residues or cover crops, and sensible diversification/crop rotations for achieving higher productivity. The technologies of CA provide opportunities to reduce the cost of production, save water and nutrients, increase yields, increase crop diversification, improve efficient use of resources, and benefit the environment. CA is developed as a technically viable, sustainable and economic alternative for current crop production practices. Current crop production systems have resulted in soil degradation, desertification, higher cost, poor soil health and unstable crop production. The adoption of no tillage has been found to enhance soil biological process, conserve soil and water, resource use efficiency, better soil condition, stable and higher yield. CA being recognized as holistic crop management for sustainable farming and it should be adopted the areas where CA adoption is low. The main barrier to its adoption is less skill/knowledge, mindset (tradition, prejudice), inadequate policies for the promotion of CA, availability of appropriate machines. Various report are

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

available on improved yield, profit, soil and water conservation, better soil health due to adoption of CA based practices. Soil organic carbon percentage increases and bulk density of soil decreases by the mulching (Ram *et al.*, 2013). Effective tiller number, grain yield and B:C ratio of wheat is significantly higher in zero tillage and minimum tillage compare to conventional tillage (Kumar *et al.*, 2013). Soil and water loss is less under the conservation tillage compare to conventional tillage (Ghosh *et al.*, May 2015). Grain yield, cost of cultivation, and net return of rice and wheat are more under conservation agriculture practices compare to conventional practices (Singh *et al.*, 2012). CA based practices can help in achieving stable high yield/profitability, better environment quality with higher resource use efficiency which leads to sustainable agriculture.

ADVANCES IN TOMATO IMPROVEMENT THROUGH BIOTECHNOLOGICAL APPROACH

APOORVA PALLED, J PRATHORE¹, KALPANACHOUDHARY AND AISHWARYA KUNDARGI²

College of Horticulture and Forestry Jhalawar, Rajasthan - 326 023, Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K), ² Kittur Rani Chenamma College of Horticulture, Arbhavi - 587 104

Tomato is called Love of Apple in England, Poor man's orange in India, it is the protective food which provides almost all types of vitamins and minerals in quite fair amount and is the number one processed vegetable in the world. Improvement in tomato is very much needed to produce elite varieties having desirable attributes like high yield, resistance to biotic stress (insect, pest and diseases) and abiotic stress (drought, salt, frost and heat), slow ripening, varieties suitable for processing and long distant transport. Biotechnology is emerging branch of science involving tools of biology and engineering through the application of which varieties can be produced in short duration with higher quality and assurance. Various biotechnological approaches are being used in tomato improvement like molecular marker, MAS (Marker Assisted Selection), transgenic, genomics etc. Achievements in tomato breeding using biotechnological tools are 1. Flavr Saur variety having antisense gene polygalacturonase (PG) delays ripening. 2. Resistance to tomato leaf curl using coat protein. 3. Transgenics having insecticidal proteins like delta-endotoxin of *Bacillus thuringiensis* (Bt) proteinase inhibitor, lectins or enzyme (tobacco anionic peroxidase). 4. Resistance to fruit borer (*Helicoverpa armigera*) using Bt gene cry AC. 5. Transgenes chitinase and glucanase are used to generate resistance to bacterial and fungal diseases. 6. Transgenes ctx-B and tcp antigens of *Vibrio cholera* are used to develop edible vaccine.

RECENT TRENDS IN AGRICULTURE SCIENCES AND TECHNOLOGY

ARCHAR

Department Of Genetics And Plant Breeding, Institute Of Agricultural Sciences, Banaras Hindu University, Varanasi-221005

Landscape implications of bio energy feedstock choices are significant and depend on land use practices and their environmental impacts. Although land use changes and carbon emissions associated with bio energy feedstock production are dynamic and complicated, ligno cellulosic feed stocks may offer opportunities that enhance sustainability when compared to other transportation fuel alternatives. For bio energy sustainability, major drivers and concerns revolve around energy security, food production, land productivity, soil carbon and erosion, greenhouse gas emissions, biodiversity, air quality, and water quantity and quality. The many implications of bio energy feedstock choices require several indicators at multiple scales to provide a more complete accounting of effects. Ultimately, the long term sustainability of bio energy feedstock resources (as well as food supplies) throughout the world depends on land use practices and landscape dynamics. Land management decisions often invoke trade offs among potential environmental effects and social and economic factors as well as future opportunities for resource use. The hypothesis being addressed in this paper is that sustainability of bio energy feedstock production can be achieved via appropriately designed crop residue and perennial ligno cellulosic systems. We find that decision makers need scientific advancements and adequate data that both provide quantitative and qualitative measures of the effects of bio energy feedstock choices at different spatial and temporal scales and allow fair comparisons among available options for renewable liquid fuels.

KEYWORDS : Landscape, carbon emission, sustainability, feedstock, land management.

RECENT DEVELOPMENT OF FERTILIZERS AND THEIR ROLE IN PRECISION FARMING

ARCHANA KUMARI*, VINOD KUMAR, GARIMA SINGH

Department of Agronomy, Bihar Agricultural University, Sabour, Bhagalpur, Bihar (813210)

Aim of fertilizer application is to provide nutrients to plants and to increase or sustain optimal crop yield. Proper use of fertilizer is beneficial to both crop production and the environment. The fertilizer industry faces a new challenge to improve its products by increasing the efficiency of their use, particularly of nitrogenous fertilizers and to minimize any possible adverse environmental impact. This can be done either through improvement of fertilizers already in use, or through development of new specific fertilizer types. The

current trends show that the marginal productivity of soil in relation to the application of fertilizers is declining. Fertilizer use efficiency in Indian agriculture is quite low even with good management practices. Efficiency of N fertilizer use seldom exceeds 40%. P and micronutrients the efficiency is only 20% and 2%, respectively and for K the efficiency is about 50%. This lead to the development of Ideal fertilizer which release nutrients in a sigmoidal pattern for optimal plant nutrition and reduction in nutrient losses. In EEF concept, the fertilizer formulations are capable of minimizing the various losses and enhance the use efficiency of the nutrients by providing the continuous availability of the plant nutrients throughout the plant growth. Precision agriculture practices using high-tech equipment has the ability to reduce agricultural inputs by site-specific applications as it better target inputs to spatial and temporal needs of the fields, which can result in lower greenhouse gas emissions. All Enhanced Efficiency Fertilizers (EEF) fertilizers are economically quite expensive but that can be compensated through higher efficiency and because of higher nutrient use efficiency and environmental impacts due to fertilizers pollution can be effectively managed. Research and development shall continue to pursue new alternative like precision nutrient management and other innovative technology in terms of fertilizer production and use efficiency to sustain crop production with minimum environmental hazards.

PROTECTED CULTIVATION IN HORTICULTURE CROPS

ARCHI GUPTA

Dept. Of Horticulture, SVPUAT, Meerut

In the present scenario of perpetual demand of horticultural produces and shrinking land holding drastically, protected cultivation is best alternative and drudgery less approach for using land and other resources more efficiently. In protected environment (greenhouse, glass house, polyhouse), the natural environment is modified to suitable condition for optimum plant growth which ultimately provides quality horticultural produces. Demand for horticulture commodities is increasing over a period of time. The production of quality fruits, vegetables, flowers and other horticultural crop can be enhanced either by increasing productivity, use of improved cultivars/hybrids and effective production system, bringing additional land under horticultural crops or by promotion of protected cultivation which supports production in adverse climatic condition, and during off season. Greenhouse cultivation is useful and is in practice in all kinds of climatic conditions, may be it be severe and extreme cold, intolerant summer, excessive rains etc. Nursery production of horticultural crops under protected conditions is highly economically viable. Greenhouse for vegetable production encompasses glass house, polyhouse, and insect proof net house. Use of techniques like soilless culture, hydroponics, aeroponics, production of hybrid seed of important vegetable crops and grafting of promising varieties on desirable root stock can be made more efficiently under protected environment.

EVALUATION OF MANGO (*MANGIFERA INDICA* L.) CULTIVARS ON THE BASIS OF QUALITY CHARACTERS OF FRUIT UNDER FAIZABAD CONDITION

ARCHIT SINGH* AND SANJAY PATHAK

Department of Fruit Science, College of Horticulture & Forestry, Narendra Dev University of Agriculture and Technology, Faizabad 224 229 (U.P.) India

The experiment was carried out at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) The experiment on mango was conducted in Randomized Block Design (RBD) with twelve treatments were Each variety was replicated thrice and spaced at a distance of 10 × 10 m. Plants were of uniform in age (22 years) and received same cultural practices during the course of investigation. The Selected varieties were Dashehari, Banarasi Langra, Langra Kukori, Bombay Green, Nisar Pasand, Gulab Khas, Himsagar, Lucknow Safeda, Rataul, Gaurjeet, Samarbahist Chausa and Zardalu and used as treatments T₁, T₂, T₃, T₄, T₅, T₆, T₇, T₈, T₉, T₁₀, T₁₁ and T₁₂ respectively. The observations were recorded on physico-chemical characters of mango fruits. The maximum fruit length (9.37cm) was recorded in Samarbehist Chausa, whereas the highest fruit breadth (6.57cm) was recorded in Bombay Green. The maximum fruit weight (186.67gm), fruit volume (179 cm³), pulp weight (135.50 gm) and pulp: stone ratio (6.66) and minimum stone weight (20.33 gm) were recorded in Banarasi Langra. Better quality fruits with respect to highest total soluble solids (20.78 Brix^o), reducing sugars (3.98%) and lowest acidity percentage (0.24%) were recorded in samarbahist Chausa. The highest ascorbic acid (74.28 mg/100gm) and total sugars (15.54%) were recorded in Banarasi Langra. While, the maximum non-reducing sugar (13.08%) was recorded in Rataul. Overall it can be concluded on the basis of quality of fruits, Bombay Green and Gulab Khas were observed as early variety whereas Dashehari, Banarasi Langra and Langra Kukori as mid season variety and Samabahist Chausa as a late variety to be found best under Faizabad condition. These varieties posses good quality characters and superior overall the varieties under this study.

Key words: Mango, Cultivars, Peel, Fruit, Sugar

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**EFFECT OF INM ON GROWTH AND YIELD OF SPROUTING BROCCOLI {*BRASSICA OLERACEA* (L.) VAR. *ITALIC PLANCK*}****ARJUN LALOLA*, L. N. BAIRWA, MALEE RAM JHAJHRA AND RAJ KUMAR JAKHAR***Dept. of Horticulture, S.K.N. College of Agriculture, Jobner (Jaipur)*

The field experiment was conducted at Horticulture Farm, S.K.N. College of Agriculture, Jobner (Jaipur) during *Rabi* season 2016-17 and 2017-18. The experiment consisted of seven treatment of INM i.e (1) 100 % RDF through inorganic fertilizer, (2) 75% RDF through inorganic fertilizer + 25 % through FYM, (3) 50% RDF through inorganic fertilizer + 50% through FYM, (4) 100 % RDF through FYM, (5) 75 % RDF through inorganic fertilizer + 25% through VC, (6) 50 % RDF through inorganic fertilizer + 50% through VC and (7) 100 % RDF through vermicompost with three replications. The application of 50 % RDF through inorganic fertilizer and 50 % through vermicompost was found significant effective and recorded maximum plant height, number of leaves per plant, leaf area, chlorophyll content in leaves (2.96mg/g), leaf area duration, weight of primary curd (222.51g), number of secondary curds per plant (6.58), weight of secondary curd (154.05 g), volume of curd (119.78 cc), diameter of curd (13.10 cm), yield per plant (384.56g), yield per plot (7.69 kg), yield per ha (189.90 q), biological yield per ha (1081.85 q). This treatment was also recorded minimum days taken to curd formation. It was statistically at par with 75 % RDF applied through inorganic fertilizer with 25 % through vermicompost.

Key Words: Growth, Yield, Organic, Inorganic, Vermicompost and Sprouting broccoli.

TO STUDY THE MANGO HOPPERS *AMARITODUS ATKINSONI* (L)**ARUN KUMAR*, SUCHARU SINGH*, MOHD. YAMEEN* AND RAJENDRA SINGH,***Department of Entomology**

Sardar Vallabhbhai Patel University of Agricultural and Technology, Meerut U.P

Mango Hopper is a serious pest of mango crop and three species of mango hoppers are causing considerable yield loss up to 60 per cent and failure of good crop. Hoppers lay egg singly on floral shoots, buds and tender leaves which hatch in a week. After hatching Large number of nymphs is pale yellow and adults vary in size from small to large depending on the species. Adults may be dark with wavy lines on wings and three spots on scutellum, or light brown with dark spots on the vertex. Nymphs and adults damaging both as puncture and suck the sap of tender parts of panicles, inflorescence, leaves and fruit. It results into weakening of inflorescence and affects fruit set and their drop. They also damage the crop by excreting sweet sticky substances which facilitates the development of sooty mold, a fungus, which affects photosynthesis activity of leaf. Based on the Studies If the timely interventions are not taken, the quality of the fruit is affected and may cause considerable yield loss.

EFFECT OF DIFFERENT HERBICIDE COMBINATION ON NUTRIENT STUDIES AND NET RETURN OF TRANSPLANTED RICE IN WESTERN UTTAR PRADESH**ARUN KUMAR***Department Of Agronomy, PAU Ludhiana-141004*

A field experiment was conducted with the aim to know effects of different weed management on nutrient studies and net return of transplanted rice in western Uttar Pradesh during *Kharif* 2016 at Crop Research Centre of Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut, U. P. (India). The experimental site was sandy loam in texture, low in organic carbon and available N, medium in available P and K and slightly alkaline in reaction. The experiment was laid out in randomized complete block design with three replications comprising twelve weed management treatments. The results indicated that the lowest N,P&K content in weeds at harvest stage found with the application of Pyrazosulfuron fb Bispyribac Sodium (150 g a.i ha⁻¹PE fb 25g a.i ha⁻¹POE) was at par with Pyrazosulfuron fb Azimsulfuron (150 g a.i ha⁻¹PE fb 30 g a.i ha⁻¹POE) and the highest were found in weedy check. The highest rice grain N,P&K content found with the application of Pyrazosulfuron fb Bispyribac Sodium was at par with Pyrazosulfuron fb Azimsulfuron. Among weed control treatments significantly highest N,P&K uptake 112.51, 34.94 & 135.01 kg ha⁻¹ respectively was observed in the application of Pyrazosulfuron fb Bispyribac Sodium was at par with Pyrazosulfuron fb Azimsulfuron 104.89 kg ha⁻¹ and significantly higher than the remaining treatments. The net return of rice was highest in application of Pyrazosulfuron fb Bispyribac Sodium treatment in comparison to weedy check treatment. Pyrazosulfuron fb Bispyribac Sodium recorded 59.05 % higher net return B: C ratio over weedy check. This shows that Pyrazosulfuron fb Bispyribac Sodium can be applied in transplanted rice for effective weed control, highest nutrient content in grain & straw, higher net return and B:C ratio.

Key words: Nutrient content, herbicide, net return, and weed management.

BREEDING FOR SUSTAINABLE VARIETIES: NEED OF THE HOUR**ARUN THAKUR***Department of Crop Improvement, CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) 176062*

By 2050, the world population will increase from recent 7.6 billion to 10 billion. This 30% increase in population will increase the need for food. With the current trends in growing food crops all around the world, agriculture often places significant pressure on natural resources and the environment without leaving a window large enough for these resources to replenish. Current demand for food and other agriculturally derived products by ever increasing population of the world doesn't leave an option for food growers. Furthermore, the amount of arable land for crop cultivation is limited and decreasing due to urbanization, salinization, desertification and environmental degradation. So, sustainable agriculture is the need of the hour. Plant varieties currently grown by farmers in India and abroad tend to be of narrow genetic base, with landraces decreasing significantly year after year leading to loss of biodiversity. This leads to farmer changing their varieties more often than before leading to more stress on land. In the recent era of GMOs dominating the agriculture, many studies have shown that these transgenic crops tend to consume considerably more nutrition than the regular non-GM crop. Plant breeding strategies for sustainability aim to develop crops which entail rationalization between yield and quality. Plant breeding methods that involve sustainability tend to put less stress on existing diversity and more on exploiting the existing variability. Generation of new variability would include tapping into new plant genetic resources to bring forth new genes for yield, stability and adaptability, resistance to diseases, pests and drought. The farmer would possess varieties that would have incorporated and mixed the genetic diversity from wild relatives. The created crops would have more variability available to farmer and breeder than before. This would lead to consistent performance in agriculture yield and quality resulting in growing food in an ecologically and ethically responsible manner that does not harm the environment and sustains communities.

Keywords: biodiversity, environment, landraces, sustainability, quality and yield

EFFECT OF DIFFERENT PH AND TEMPERATURE LEVELS ON MYCELIAL GROWTH OF *PLEUROTUS CORNUCOPIAE* (BRANCHED OYSTER MUSHROOM)**ARUNESH KUMAR^{1*}, R.S JARIAL², KUMUD JARIAL³ AND SAVITA JANDAIAK⁴**

^{1* & 4} *Department of Plant Pathology, College of Horticulture,* ^{2 & 3} *Department of Plant Pathology, College of Horticulture and Forestry Neri-Hamirpur 177001, YS Parmar University of Horticulture and Forestry, Nauni-Solan (HP) 173230*

Pleurotus cornucopiae, the branched oyster mushroom is one of the *Pleurotus* species whose cultivation is not common in India. The physiological/cultural studies were conducted to evaluating different pH and temperature levels for the mycelial growth of *P. cornucopiae*. The test fungus was evaluated for its tolerance to low and high Ph levels. Out of different pH regimes ranging from 4.0 to 8.0 tested and pH 7.0 was found to support maximum average diametric growth (83.25mm) and minimum growth (53.91mm) was observed at pH 4.0. In all the treatments, type of growth ranged between sparse, fluffy to thick strandy. Six different temperature regimes ranging from 10 to 35°C were evaluated, the maximum average diametric growth (85.00 mm) was observed at temperature 25°C and minimum (39.16mm) was observed at 10°C. The type of growth at different pH & temperature's ranged between strandy, sparse, fluffy and thick strandy. Data were recorded after 7 days of inoculation of test fungus in both that is pH and temperature.

Keywords: temperature, pH, *Pleurotus cornucopiae*, diametric growth, average biomass, colour of mycelium and type of growth.

WHEAT PRODUCTION STRATEGIES UNDER THE CLIMATE CHANGE SCENARIO TO IMPROVING THE CROP PRODUCTIVITY**ARVIND KUMAR***G.B. Pant University of agriculture and technology, Pantnagar, US Nagar, Uttarakhand 263145.*

Over the past decade experienced suggest that climate will be even more variable in the future. Both rainfall pattern and temperature are more variable due to climatic aberrations which have much affected the agriculture. Wheat crop require an optimal conditions for their growth and production but alteration in growing environment directly influences the wheat development and production. It may causes; Wheat rapid development, Early Flowering and fasten the maturation due to increasing temperature and growing degree days. Photosynthetic rate, dry matter accumulation and water uptake are enhanced due to increased atmospheric CO₂ which resulting more demand of soil nutrients and yield reduction of wheat under current nutrients application rates. Accurate estimation of climate change impact on wheat is not possible due to many interactions within planting date, water availability, nutrients and crop variety. Therefore to achieve the potential yield target, Wheat growers need to focus on various short, medium and long-term management options that involving knowledge and input intensive systems of cultivar selection, nutrient and water management. In case of short term options, combination with strategic nutrient management and Irrigation has much potential to significantly improve the yields. Growers can also

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

use such varieties which are better suitable for warmer climate, late seasonal rainfall and shorter durations. Whereas, in Medium to Long-term options, Growers are need to focus on closely match the nutrient application with crop demand to maintain of the current yield levels. However, Delaying the nutrient applications or leaching in wet conditions may cause some nutrient deficiency. The use of slow release fertilisers to assist in preventing nitrogen deficit may be used. However, Early Flowering and maturation in wheat will likely influence future cultivar selection and sowing window. So, the future wheat production can be improved by using different crop management options.

ORGANIC MULCH: BETTER TECHNIQUE TO CROPPRODUCTION FOR SUSTAINABLE AGRICULTURE

ASHISH K. SINGH, DHIRENDRA K. SINGH, LAVLESH, SANDEEPYADAV AND ABHILASH SINGH

Department of Vegetable Science, Govind Ballabh Pant University of Agriculture and Technology, Pantnagar (Udham Singh Nagar - 263145), Uttarakhand, India.

Indian Agriculture is mostly depending on the heavy application of fertilizer, pesticides, irrigation and several other agricultural inputs. They are constantly degrading and polluting the quality of soil, water and our environment. The farmers are using excess doses of fertilizers and pesticides to increase the yield of the crop, but these over doses are hazardous for our soil health. Use of organic mulching is one of the suitable methods which could help the growers to increase the production with good quality of produce. Organic mulches are those natural origin materials which can decompose naturally. It includes bark chips, grass clippings, wheat or paddy straw, plant leaves, compost, rice hulls, and sawdust, etc. It decays very rapidly and increases the water holding capacity of soil. It also restricts the weed growth by obstructing light penetration to the soil surface. Organic mulch also reduces erosion by protecting the soil surface and reduces nutrient loss by runoff and leaching. The total production of organic waste by human, livestock and crops are approximately 38 trillion metric tons worldwide, and about 600 to 700 million metric tons of agricultural wastes (as well as 272 million metric tons of crop residues) are existing every year in India. A seven-year organic mulch study in India showed that the superiority of organic mulching compared to black or transparent polythene mulch resulted in improved flowering, pod production and yield of groundnut. With proper planning, good management, attention to details, and dedication to all aspects of the cropping sequence, earlier and higher yields are possible through use of mulch. Mulching is a good practice for virus-vector management. Farmer can adopt this technique to sustain the agriculture.

EFFECT OF PHOSPHORUS AND SULPHUR NUTRITION ON SUMMER MUNGBEAN (*VIGNA RADIATA* L. WILCZEK) UNDER IRRIGATED CONDITIONS OF WESTERN UTTAR PRADESH

ASHISH KUMAR PANDEY, ADESH SINGH* AND SANJEEV SINGH

Department of Agronomy, College of Agriculture, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P.) India

A field experiment was conducted during the *summer* season of 2017 at Crop Research Centre (located at a latitude of 29° 40' North and longitude of 77° 42' East with an elevation of 237 metre above mean sea level.) of Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P.) to study the Response of *Summer* Mungbean (*Vigna radiata* L. Wilczek) to Phosphorus and Sulphur Nutrition. The soil of the experimental field was well drained, sandy loam in texture and slightly alkaline in reaction. It was low in organic carbon and available nitrogen, medium in available phosphorus, potassium and sulphur with an electrical conductivity (1:2.5, soil: water suspension) of 1.7 dS/m. The total amount of rainfall during crop period was 83.8 mm out of this 64.4 % was received during May to June. Four phosphorus levels (0, 20, 40 and 60 kg P₂O₅/ha) and three sulphur levels (control, 20 and 40 kg/ha) were tested in factorial randomized block design with 3 replications.

Results revealed that the growth parameters and yield attributing characters of mung bean viz., pods/plant, grains/pod, test weight and grain yield/plant were significantly higher at highest levels of P (60 kg/ha) or S (40 kg/ha) over their lower levels. The phosphorus @ 60 and 40 kg P₂O₅/ha over control outyielded 86.6 and 54.5%, respectively. Similarly, the per cent increment with 20 and 40 kg S/ha over control was 35.3 and 19.0, respectively. Mung bean fertilized with 60 kg P₂O₅/ha accumulated 63.7, 64.5 and 93.4 % more total N, P and S/ha over control. The respective improvement with 40 kg S/ha over control was 20.8, 2.11 and 2.62 kg/ha. However, the 40 kg S/ha registered 5.3 and 2.5 per cent higher available nitrogen over control and 20 kg S/ha, respectively. The application of 60 kg P₂O₅/ha fetched significantly highest gross returns (Rs 59863/ha), net returns and Benefit: cost ratio (2.5). However, the net benefit over and above 20 and 40 kg P₂O₅/ha was Rs 14457 and Rs 8774/ha, respectively. Among the sulphur levels, the significantly maximum gross returns (Rs 53085/ha), net returns and B:C ratio was noticed with the application of 40 kg S/ha as compared to rest of the treatments.

INNOVATIVE TECHNOLOGIES FOR HORTICULTURAL DEVELOPMENT IN INDIA**ASHISH PANWAR***Horticulture Assistant, Aga khan foundation Nizamuddin, New Delhi*

Agriculture is the back bone of Indian economy as it supplies raw material for many of the industries and it is the source of livelihood for majority of the rural population in India. There are myriad innovations that have been part of agricultural transformation in India. This paper discusses various innovative technologies for horticulture development in India. Scientists with the Horticulture Innovation Lab are testing and adapting a range of technologies aimed at significantly improving the profitability of fruit and vegetable production throughout the world. Given the complexity of horticulture, technologies such as these can reduce constraints that limit the ability of smallholder farmers to achieve maximum profitability with high-value horticultural products. Our goal is to develop and test technologies that can overcome common limitations in land, labor, capital and infrastructure.

Keywords: Innovation technologies, Institutional Dynamics, Agriculture, Horticulture development.

INHERITANCE STUDY OF RED KERNEL COLOUR IN RICE (*ORYZA SATIVA* L.) USING MICROSATELLITE MARKERS**ASHISH S. JONDHALE*, S. G. BHAVE¹, S. V. SAWARDEKAR², D. B. PATIL³**

Department of Genetics and Plant Breeding, College of Agriculture, Balasaheb Sawant Konkan Krishi Vidyapeeth, Dapoli, Maharashtra, (India)

The investigation comprised of one red kernel and one white kernel fine grained rice cultivars. Crosses between White rice x Red rice cultivars and their reciprocal were made during *Kharif* 2013. The F_1 s were evaluated during *Rabi* 2013-14 and F_2 seeds of each cross were obtained. The BC_1 and BC_2 i.e. back crosses of F_1 with both the parents were effected during *Rabi* 2013-14. The parents, F_1 s, F_2 s, BC_1 s and BC_2 s were evaluated during *Kharif* 2014. The F_1 progenies of both crosses under study were examined for the kernel colour and it was observed that all the F_1 progenies were having red coloured kernels. This indicates the dominance of red kernel colour over white kernel colour in rice in F_1 generation. For these studies molecular markers linked to the red kernel were used for parental polymorphism and for foreground selection. The parental validation using SSR markers were also studied. Marker RM 206 was found as the best marker in screening F_2 population for red kernel colour followed by RM 251 as the distance between two fragments are more. The F_2 population of both crosses was screened using selected two SSR markers i.e. RM 206 and RM 251. A representative 100 individuals derived from the crosses Karjat-2 x Munga and their reciprocal was estimated for white and red kernel colour. Out of 100 individual plants 81 and 19 were found to exhibit red and white kernel colour respectively and these individuals were segregated in 3:1 chi square ratio for kernel colour trait.

A REVIEW ON ABIOTIC STRESS TOLERANCE IN BANANA**ASHOK KUMAR MEENA, FRANCIS DUTTA, BHUJBAL SINGH AND PRAVEEN KUMAR***Department of Horticulture, Assam Agricultural University, Jorhat*

In India, bananas are grown in the regions of humid tropics, humid subtropics and semiarid tropics, and some banana genotypes can grow up to an elevation of 2000 MSL. Deep, well-drained loamy soil with adequate organic matter is ideal for its cultivation. Bananas (referring to banana, plantain and cooking bananas) are economically important high-value commercial as well as subsistence food crop. The most suitable climate is with warm moist weather without strong winds throughout the year. The major abiotic factors which influence the banana growth and productions are water, temperature, wind and mineral nutrients. The major constraints for banana production are largely dominated by biotic and abiotic stresses. Though research on biotic stresses in banana has drawn sufficient attention worldwide, abiotic stresses are not. The successful cultivation of water-loving Cavendish clones, in drought-prone areas with protected irrigation, has provided the sufficient momentum to research on drought in bananas. Banana plants, especially the Cavendish clones, are sensitive to abiotic stresses like soil moisture deficit, salinity, extreme temperatures and strong winds. As bananas are recalcitrant to conventional breeding approaches, clonal selection and tolerant genotype selections from germplasm are the major sources to address the abiotic stresses. Stress resistance mechanism are avoidance (preventing exposure of plant to the stress), tolerance (allowing the plant to withstand against the stress) and acclimation (altering the physiology in response to the stress).

Keywords: Banana, Abiotic stress, nutrients, salinity

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**WATERPROOFING CROPS****ASHOK SINGAMSETTI^{*1}, SWATHI REKHA NANDIGAM², KRISHNAVENI VARALA³***Department of Genetics and Plant Breeding, Banaras Hindu University, Varanasi, U.P., Department of Genetics and Plant Breeding, Birsa Agricultural University, Ranchi, Jharkhand., Department of Plant Pathology, Birsa Agricultural University, Ranchi, Jharkhand.*

In farming regions all over the world, in past 50 years, the extremes in water availability like drought and flood had increased its frequency. These two abiotic stresses are accounting to a loss of many US billion dollars all over the world. The crops which are mostly affected by these abiotic stresses include Rice, Maize, Soybean, Wheat and Cotton. Among these, the most flood-threatened crop is Rice. At present, over 35% of world's rice acreage is flood prone and much of this is in regions of Asia and Africa which are characterized as food insecure continents. This problem is considered as a major one and became a major international goal for the rice breeders to meet the anticipated needs of growing hunger mouths. To achieve this, adopting and developing a germplasm that can bear these abiotic assaults is essential. For this, development of rice varieties that survive transient submergence and their non-commercial dissemination to farmers cultivating flood prone paddies. For this content, through the initiatives of IRRI, robust submergence tolerance was transferred by MAS from farmer's landrace to modern varieties. For translation of flooding survival strategies to additional crops for stabilizing yields of food, feed, fiber and fuel, an entire knowledge on developmental, morphological, physiological and molecular mechanisms that underlie flood tolerance should be known.

DETECTION OF SUGAR BEET VARIETIES HAVING HIGH SUCROSE CONTENT AND YIELD FOR SUB-TROPICAL CONDITIONS OF INDIA**ASHUTOSH KUMAR MALL, VARUCHA MISRA, A. D. PATHAK***ICAR-Indian Institute of Sugarcane Research, Lucknow*

Sugarbeet is a renowned crop standing second position for contributing to sugar production in the world after sugarcane. It is now gaining attraction for production of ethanol due to high potential content of 7000 litre/ha in it. It is a water saving crop where water can be saved up to 30-40 % and its leaves are useful as a good fodder material. The problem of high consumption of sugar due to high population rate and climate change is making this crop an important one. To manage this problem there is a need for developing high sucrose content and yield sugarbeet varieties especially for the sub-tropical regions of India. Thus, the present study highlights on detecting such high sucrose content and high yield sugarbeet germplasm. In respect to control (LS 6), thirteen varieties have been assessed under this study. Study revealed that Shubra had highest population survival capability amongst all varieties tested against check. In respect to sucrose content and commercial beet sugars per cent and root yield, Shubra again bagged the first position. Contrastingly in root diameter aspect, it owes the second position followed by L 33 AND LKC 2007 whereas the first position was attained by R 06 against check variety. The study concluded that amongst all the varieties tested for high sucrose content and yield, Shubra is one of the promising varieties for sub-tropical conditions of India.

Keywords: Germination, LS 6, Sucrose, Shubra, Sugarbeet, Yield

RECENT HEADWAY IN SEED PRODUCTION OF ROOT CROPS**ASHUTOSH KUMAR, ¹MAHENDRA KUMAR TAL, ²ABHIVYAKTI AND ¹R. B. VERMA***Deptt. of Horticulture (Veg. & Flori.), BAU, Sabour-813210, Deptt. Of Agricultural Meteorology, BAU, Kanke- 834006*

Root crops consider carrot, radish, turnip, beetroot and parsnip etc. and are extraordinarily imparting to the vegetable production basket in India. Due to the advancement of varieties for round the year production off-season production and storage facilities, radish and carrot stay in the market most of the year. At national level National Seed Corporation (NSC) and at state level State Seed Corporations (SSCs) are accountable for quality seed production. There is an ample disparity between the quest of quality seed and circulation. This space is bridge up to some extent either by the private sector companies or from the own farm save seed by the farmers. To improve use of quality seed, there is a demand of production of quality seeds and also need for the development of seed production practices of root crops in order to potentiate the accessibility of quality seed for commercial production in these crops. Although, root crops are well naturalizing to cool season but their seed production are being done in plain & hills during winter or after overwintering. The Asiatic/tropical varieties produce their seeds freely in the plain without chilling requirement (for bolting). The temperate/European types need chilling/vernalization stimulus of 4-5°C temperature for 40-60 days' duration for bolting depending upon the range of temperature. Due to limited activity of honeybee at the high temperature i.e. 32°C or above the seed setting hampered in radish as well as turnip. Similarly, high temperature at flowering in carrot also causes desiccation of tertiary umbels due to reduced availability of pollen supply for secondary umbels and reduced the seed setting resulting in lower seed yield.

BOTANICAL MANAGEMENT DOWNY MILDEW OF OPIUM POPPY**NARENDRA DEV UNIVERSITY OF AGRICULTURE AND TECHNOLOGY**

Department of Plant Pathology Faizabad, Ashwani Kumar Patel, M.Sc. Ag & Pawan Singh,, Satyendra Vishwakarma

Opium poppy (*Papaver somniferum L.*) is the most important medicinal plant. It has its importance as a plant based natural reliever from the time dating back to early civilization till today. It is an important crop of India because it produces capsules that contains milk from which opium is prepared. Opium possess various types of alkaloids which are used for preparing medicines for the use of human and cattle. There are 25 alkaloids identified in raw opium; of them, morphine, narcotine, codeine phosphate, narcein, thebaine, papaverin, etc are important. Opium poppy is susceptible to a number of diseases which affect the opium yield, most of which can be classified as fungal diseases and other diseases are bacterial, viral etc. Among fungal disease of opium poppy Downy mildew is most common disease present on opium plant. Downy mildew of opium poppy caused by *Peronospora arborescens* (Berk) de Barry was first reported from India by Butler in 1918. During late of December and starting of January mid, symptom of downy mildew were observed on 2 month old plant at Medicinal and Aromatics plant Experiment Station of Horticulture farm Narendra Dev University of Agriculture and Technology Kumarganj faizabad. The leaves symptoms were collected in morning from farm of MAP Experiment of Horticulture faizabad and brought to laboratory and cottony growth on downy region of leaves is isolated and Slide is prepared and it is observed under light compound microscope. It reveals the large number of short lived sporangia and Sporangiospores. The Sporangiospores were hyaline and upper portion is dichotomously branched, the sporangia were pale/ light brown, sub globose, ellipsoidal. Its sizes measure were as follows Sporangiospore branches measure 75 to 240µm long × 2.5 to 8 µm wide. The size of Sporangia is measured 20 to 34 µm long × 18 to 20 µm wide. The Botanical management of Downy mildew was done at field experiment station at trial of Opium poppy crop using Neem seed kernel extract's, and Neem cake, and Naturally available Buttermilk and Garlic extracts and one treatment with control. Observation after treatment with Botanical agent on opium crop reveals that botanical management are satisfactory for control of downy mildew disease.

GROUNDWATER STORAGE ANALYSIS IN CHANGING LAND USE IN AGRICULTURE**ATIN KUMAR¹, SATENDRA KUMAR¹, ASHOK KUMAR¹, ROHIT KUMAR² AND SHRIMAN KUMAR PATEL³**

¹Department of Soil Science and Agricultural Chemistry, ²Department of Agronomy, College of Agriculture, SVP University of Agriculture & Technology Modipuram, Meerut 250110, ³Department of Soil Science & Agricultural Chemistry, Bihar Agricultural University, Bhagalpur, Bihar, India 813210

Groundwater is a major source of drinking water across the world and plays a vital role in maintaining the ecological value of many areas. However, the quantity and quality of groundwater are changing due to human activity. Assessing the impact on the groundwater system and predicting the magnitude of change in the future is therefore a major scientific challenge. Land-use and land-cover changes are one of the main human induced activities altering the groundwater system. Nevertheless, the impact of future land-use changes on the groundwater system has not been investigated extensively. Throughout the entire history of mankind, intense human utilization of land resources has resulted in significant changes of the land-use and land-cover. Since the era of industrialization and rapid population growth, land-use change phenomena have strongly accelerated in many regions. The impact of land use and land cover changes on the regional water balance is the most vigorous research in the international hydrological fields, and lots of research indicate that large-scale land use and land cover changes are the important factors resulting in the regional climate and hydrological cycle changes. Over the last century, major changes in land use have occurred locally, regionally and globally. These will continue in the future too. The impact of urbanization on groundwater has a major concern over past few decades, and in particular, to those involved in groundwater quantity and qualitative studies. Increased impervious area due to urbanization results in decreased infiltration, and finally affecting the groundwater storage. Thus, land use changes have to be assessed with spatial data technologies; especially the application of remotely sensed data and geographical information systems (GIS) has been used. During the last five decades there has been sharp increase in water consumption owing to the population explosion, unprecedented rise in standard of living and enormous development. The problem is caused not only by natural factors, but also due to mismanagement and lack of knowledge about existing water resources. Therefore, a proper management plan can only be adopted by knowing the balance of different hydrologic components of hydrological unit.

Key Words: Groundwater, water, land-use, climate, GIS etc.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**NUTRIENT CONTENT OF IMPORTANT FRUIT TREES FROM DRY AREA OF RAJASTHAN****ATMARAM MEENA¹, BHAGWATI BARANDA² PUSHPENDRA SINGH³***1, 2, College of Agriculture, S.K.R.A.U-Bikaner, Rajasthan -334 006 (India), 3, Rajasthan College of agriculture, MPUAT-Udaipur, Rajasthan*

Forests have provided food and shelter to man since ages. About 20% of the plants occurring in the forests are reported to have direct utility to mankind. Around 600 plant species in Indian forests are enumerated to have food value. Arid zone vegetation comprises a wide range of edible fruit bearing and food producing species viz. *Capparis decidua* (Ker), *Cordia dichotoma* (lasora), *Ziziphus mauritiana* (ber), *Ziziphus nummularia* (Bordi), *Salvadora oleoides* (Jal), *Balanites aegyptiaca* (Hingota), *Prosopis cineraria* (Khejri) etc. which play an important role in the nutrition of children in rural and urban areas alike and are relished by them. Most of these fruits are rich sources of protein and energy. Ker is a rich source of fibre, vitamin A and vitamin C. Ber is richer than apple in protein, phosphorous, calcium, carotene and vitamin C. However they are often undervalued and underutilized as more exotic fruits become accessible. Also most of these are not cultivated and there is only scant and dispersed knowledge about them. Their production and consumption provides a dietary supplement as well as commercial opportunity. Potential fruit species from arid region are reviewed in context with their nutrient contents.

Key words: Fruits, nutrition, protein, vitamin A, energy.

CHARACTER ASSOCIATION STUDIES IN OATS (*AVENA SATIVA* L.)**ATMAN POONIA & D S PHOGAT***Department of Genetics and Plant Breeding, CCSHAU, Hisar*

Oat (*Avena sativa* L.) is a cereal crop of global importance, belonging to the family. Oat (*Avena* spp.) has a taxonomic pattern similar to that of wheat, consisting of a polyploid series of species with seven basic ($x=7$) chromosomes, i.e., diploid, tetraploid and hexaploid. The multifunctional uses of oats include forage, fodder, straw for bedding, hay, haylage, silage chaff, human food; most commonly, they are rolled or crushed into oatmeal, or ground into fine oat flour. The present investigation was carried out in Forage Section Department of Genetics & Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar during *rabi* 2015-16 to estimate the magnitude of correlation among fodder yield and seed yield. Positive and significant correlations of dry matter yield per meter row length were recorded for seed yield per meter row length and green fodder yield per meter row length. Hence, it would be rewarding to lay stress on characters viz. green fodder yield and seed yield per meter row length for the improvement of dry matter yield.

Key Words: correlation, *Avena sativa* L., selection, fodder

SOIL HEALTH MANAGEMENT: A QUALITATIVE APPROACH**ATUL DHANSIL¹ BHAWANI SINGH PRAJAPAT² AND KAMLESH YADAV³***¹Deptt. of Agril. Chem. and Soil Science, College of Agriculture, JAU, Junagadh, Gujarat, ²Deptt. of Agronomy, Rajasthan College of Agriculture, MPUAT, Udaipur, Rajasthan, ³Deptt. of Agril. Chem. and Soil Science, Rajasthan College of Agriculture, MPUAT, Udaipur, Rajasthan*

India is a predominantly agricultural country in which major part of GDP depends on agricultural commodity. The soil health is one of the most important factors in deciding production potential of particular soil in relation with present situation as well as future use. Soil health is the 'fitness' or 'condition of soil' to sustainably support specific uses (e.g. crop growth) in relation to its potential, as dictated by the inherent quality of the soil. The soil health is basically the integration of the soil physical, chemical and biological processes and functions. A healthy soil will be balanced for all the three components. In order to make interpretation of the health of a soil, the various processes and functions need to be assessed through meaningful indicators (on the basis of cumulative rating of all indicator). Soil health is an assessment of ability of a soil to meet its range of ecosystem functions as appropriate to its environment. The term of soil health is used to assess the ability of a soil to sustain plant and animal productivity and diversity, maintain or enhance water and air quality, and support human health and habitation. Soil health deals with both inherent and dynamic quality. Inherent quality relates to the genetic characteristics while dynamic soil quality is affected by management practices. The inherent and dynamic soil quality components do interact.

Key word: Soil health, indicator, inherent and dynamic quality, production

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**“TECHNOLOGICAL GAP OF FARMER IN WHEAT CROP CULTIVATION”****ATUL KUMAR^{*1}, R.K. DOHAREY², KAUSHIK PRASAD³, KAMAL KISHORE⁴, ARVIND PRATAP SINGH⁵, AND MANOJ KUMAR⁶**^{1,2,3,4,5,6} *Department of Extension Education, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India*

The study was conducted in Harpalpur and Madhoganj block of Hardoi district (UP) selected purposively, because block area has more popular for area and production of wheat as criteria. A total number of hundreds wheat growers were selected through random sampling from five selected villages panchayats on the basis of twenty respondents from each selected villages panchayats. The technological gap with result of Wheat cultivation ranged from to (7.5 to 42.5 per cent). The highest gap was found in farmer about knowing of the plant protection. The second major technological gap of 28.75 per cent was noticed in harvesting and 28.33 percent of seed treatment and their characteristics. A gap of 28.33 per cent was found in weed management and 18.75 per cent was found in land preparation, 18.00 per cent was found in sowing method. I remaining practices such as seed rate, variety, method of application, intercultural operation, manure and fertilizers, selection of soil, irrigation and variety the gap were reducing from 16.66 per cent to 7.50 per cent.

Keywords: Technological Gap, knowledge, *adoption*, scientific cultivation, etc.

EFFECT OF SITE SPECIFIC NUTRIENT MANAGEMENT IN RICE**ATUL KUMAR*, VIPUL KUMAR MISHRA*****Dept. of soil science, RAU, Pusa- 848125, **Msc Research Scholar, Dept. of soil science, RAU, Pusa- 848125*

Rice (*Oryza sativa* (L.)) is one of the most important staple food crop in the world. In Asia, more than two billion people are getting 60-70 per cent of their energy requirement from rice and its derived products. In India, rice occupies an area of 44 million hectare with an average production of 90 million tonnes with productivity of 2.0 tonnes per hectare. Nutrient management is a major component of a soil and crop management system. Site specific crop and soil management is basically taking a systematic approach to applying sound agronomic management to small area of a field that can be identified as needing special treatment. At present the site specific nutrient management for rice crop is developed and adopted by the farmer all over the world. Many of nutrients required by rice plants come from soil. But the supply of nutrients is typically insufficient to meet the nutrient requirements for high rice yields. The use of fertilizer is consequently essential to fill the gap between the crop needs for nutrients and the supply of nutrient from soil and available organic inputs. Site Specific Nutrient Management (SSNM) is an approach to feeding rice with nutrients as and when needed. The application and management of nutrients are dynamically adjusted to crop needs of the location and season. The SSNM approach aims to increase farmers profit through, increased yield of rice per unit of applied fertilizer, higher rice yields, and reduced disease and insect damage. Site Specific Nutrient Management (SSNM) provides an approach for feeding rice with nutrients as and when needed. SSNM eliminates wastage of fertilizer by preventing excessive rates of fertilizer and by avoiding fertilizer application when the crop does not require nutrient inputs. It also ensures that N, P, K are applied in the ratio required by the rice crop. Site specific nutrient management is a concept that can be applied to any field or any crop, while most often use of computer and satellite technology in the site specific nutrient management does not require special equipment and does not require a large farming operation. The technology tools certainly expand the capabilities for using site specific management.

Key words: Rice, Site Specific Nutrient Management (SSNM), N, P, K, yield.

PROSPECTS OF DOUBLED HAPLOID BREEDING IN MAIZE (ZEAMAYS L.)***ATUL LOYAL¹, SAWAN KUMAR¹ AND SIDHANT CHAUDHARY²**¹*Department of Crop Improvement, CSK Himachal Pradesh Agricultural University, Palampur, H.P. (India) 176062, ²Institute of Plant Breeding, University of Hohenheim, Stuttgart (Germany) 70599*

Maize (*Zea mays* L.) is an important food crop after rice and wheat. Successful hybrid production requires the development of true breeding homozygous inbred lines. In conventional methods, inbreeding of maize required repeated self-pollination for six to eight generations to get enough homozygosity in inbred lines. The key to the accelerated development of hybrids is reducing the time required for inbred development. The doubled haploid (DH) technology is an alternative approach which shortens the breeding cycle significantly by the rapid development of completely homozygous inbred lines within 2-3 generations. To our knowledge, all present commercial DH-line breeding programs are based on *in vivo* induction of maternal haploids. Other techniques have proven to be less effective or too genotype specific. Because of the genetic, methodological and logistic advantages, further progress in maize breeding is expected to increase considerably with the development of DH lines. Yet, the success of employing DH lines depends on a robust and efficient haploid induction technology as well as breeding strategies that make optimum use of the breeder's genetic, technical and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

monetary resources. An important aspect of the DH approach is to limit the loss of genetic variance due to random drift and selection by maintaining a minimum effective population size. To comply with this requirement, considerable numbers of DH parent lines need to be inter-crossed for starting a new selection cycle. In maize, *in vivo* induction of haploids is done by crossing source material with various maize inducer lines. Haploids are screened using various morphological (seed color, seedling root coloration) or biochemical (herbicide resistance, kernel oil content) markers. Generally, Colchicine is used as a chromosome doubling agent (or mitotic inhibitor) in DH production in maize. The seeds from the colchicine treated plants represent the newly developed, completely homozygous DH line. Implementation of DH technology requires new skills on the part of breeding programs, for both DH line production and integrating DH lines efficiently in the breeding pipeline, such as i) Optimization of DH production protocols, ii) New haploid seed identification markers and iii) Develop alternative chromosome doubling agents.

Keywords: Doubled haploid, Homozygosity, *in vivo*, Maize, Morphological markers

ANALYSIS OF GENETIC DIVERGENCE IN CHRYSANTHEMUM (*DENDRANTHEMA GRANDIFLORA* TZVELEV)
ATUL PRAKASH, MUKESH KUMAR, ARCHI GUPTA, DIPANKAR SINGH BADAL

Horticultural Research Centre (HRC) of SVPUAT, Meerut, UP

The investigation was carried out with twenty chrysanthemum genotypes at Horticultural Research Centre (HRC) of SVPUAT, Meerut, UP during 2016-17 to study the genetic diversity among the genotypes. The maximum days to flower bud initiation (43.53 days) and days to flowering (69.53 days) was observed in the cultivar of Ajay while cultivar White Star produced larger size flower (9.97 cm). The maximum flowering duration (57.53 days) was observed with the cultivar of Haldighati and maximum plant height at flower bud initiation stage (28.27 cm) and plant height at full bloom (57.53 cm) was observed with the cultivar of Sunny. Cultivar of Basanthi produced maximum number of primary branches (7.93), plant spread (70.73 cm) and maximum number of flowers (218.67). D2 analysis grouped among the genotypes into five clusters showing the existence of considerable amount of variation among the genotypes. Cluster pattern revealed that, cluster V had largest number of 6 cultivars, followed by cluster III (5 cultivars), cluster II (4 cultivars), cluster IV (3 cultivars) and cluster I had only (2 cultivars). Highest intra-cluster distances were found for cluster III ($D_2 = 2.117$) whereas, highest inter-cluster distance was observed between clusters V and IV ($D_2 = 4.402$). The cluster means revealed the best cluster for various growths and flowering traits depending upon the aim of breeding programme and potential line can be selected from different clusters as parents.

POSTHARVEST HANDLING OF MANGO
ATUL YADAV AND ABHINAV KUMAR

Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad

Post-harvest management means the handling of an agricultural product after harvest to prolong storage life, freshness and an attractive appearance. In order to deliver a quality product to the market and ultimately to the consumer to command buyer attention and gives the grower a competitive edge, proper post-harvest management is the need of the hour. Nearly, 20-25 per cent of fruits are wasted due to faulty Post-harvest practices during harvesting packaging, storage, grading etc. This wastage can be reduced to some extent through proper and scientific methods. The pre-harvest cultural practices like use of fertilizers, pest control, growth regulators, climatic conditions like wet and windy weather and tree conditions influence the fruit potentiality for storage by modifying physiology, chemical composition and morphology of fruits. The spray of calcium is found useful in delay in ripening of Mangoes improves the storage life and increased the marketability. Similarly, pre-harvest spray of fungicide like Dithane M-45 (0.2%), Bavistin 0.1%, Topsin-M (0.1%) and Captan (0.2%) is effective in controlling storage disease due to anthracnose and stem end rot in Mango varieties. Harvesting is the most important factor, governing the post-harvest management. The harvesting of the fruit is done, either by hand picking, or plucking with a harvester at green mature stage. When the Mangoes are fully-grown and ready for picking, the stem will snap easily with a slight pull. If a strong pull is to be applied, then fruit is still somewhat immature and should not be harvested. A long-poled picking bag, which can hold nearly four fruits, is also used for plucking of the fruits.

Keywords- management, increased the marketability, harvesting, morphology of fruits etc.

EFFECT OF SPACING AND NUTRIENTS MANAGEMENT ON GROWTH, YIELD, YIELD ATTRIBUTES, QUALITY CHARACTERS AND ECONOMICS IN *HIRSUTUM* COTTON IN CENTRAL PLAIN ZONE OF U.P.
AVINASH KUMAR SINGH, JAGDISH KUMAR, RAJEEV KUMAR, SUNIL KUMAR, AJEET KUMAR

CSA University, Kanpur, UP

A field experiment was conducted, with *hirsutum* cotton genotype H-1300 during *Kharif* season 2015 at the Oil Seed Farm of C. S. Azad

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

University of Agriculture and Technology, Kanpur. The treatments were evaluated in Randomized Block Design with three replications. Crop was fertilized as per respective treatments where half of nitrogen and full dose of phosphorus and potassium was applied at the time of sowing and remaining half of nitrogen was applied in two equal installment one at 30 days after sowing and second at 60 days after sowing. Harvesting was done on the basis of picking when boll was fully open. Application of 125% RDF + 25% less than normal spacing + foliar spray of 2% urea and 2% DAP produced significantly highest growth characters viz., plant height at 30, 60, 90 and 150 days after sowing, number of monopodial and sympodial, fresh and dry weight/plant, yield attributes viz., number of bolls/m², number of bolls/plant and boll weight, yield viz., seed cotton, lint, seed and stick, quality characters viz., ginning out turn, span length, micronaire value, uniformity ratio and fibre strength and economics, it was closely followed by 125% RDF + 25% less than normal spacing + foliar spray of MgSO₄ and ZnSO₄. On the basis of above results, it may be concluded that *hirsutum* cotton genotype H-1300 along with application of 125% recommended dose of fertilizers (60:30:20 kg NPK/ha) + 25% less than normal spacing + foliar spray of 2% urea and 2% DAP was most productive and remunerative for cotton under Central Plain Zone of U.P.

IMPORTANCE OF SPIDERS ON THE SUSTAINABILITY OF AGRICULTURE AND ENVIRONMENT

***AWANEESH KUMAR, CHETHAN KUMARN, ABHINANDAN YADAV**

Dept. of Entomology, Assam Agricultural University, Jorhat-785013

The use of pesticide has grown over past 20 years to 3.5 billion kg/year, amounting to a global market worth \$45 billion. The external costs of pesticides are \$4\$19 (€315) per kg of active ingredient applied. Who's giving a great result to knock down the pest population but side by side also providing the adverse effect to our agriculture and environment. This leads to us a silent unsustainability. So, to break this unsustainability from agriculture and environment several agents (predator, parasitoid and bio agent) are used now a day. Among all these agents "spiders" are very unique and important. Spiders eat lots of insects, mostly those smaller than themselves. Taken as a whole and given the diversity of species assemblages in most ecosystems, spiders' primary niche in nearly every ecosystem is controlling insect populations. Spiders are most eerie arthropods in nature which is carnivorous in nature. They consume a large number of harmful insects. About 19 species in rice ecosystem, 13 species in maize, 16 species in soybean, 18 species in oil seeds, 21 species in cotton, 57 species in sugarcane, 13 species in vegetables, 11 species in fruit crops and 26 species in coconut has recorded. Species abundance of spider communities in agricultural ecosystem can be as high as in undisturbed natural agro-ecosystem. On the other hand spider web is also play a vital role to clean the environment. Spider web have capability to fish out the heavy metals eg. Pb, Zn from the environment, which has adverse effect on environment as well as human health. Moreover, in the winter season when frost drop down from the sky, they holds the frost particle and protect "lower and side" tillers of crops. Later these frost particles are converted in to the droplets of water through the abiotic factors and dripped by the spider webs as a natural "light drip irrigation" on the crops.

Key words- Spider, Spider web, Environment

SOIL QUALITY AND SUSTAINABLE AGRICULTURE

AYMAN JAVED¹, RAJNISH YADAV¹ AND ZAHOOR AHMAD BABA²

¹Division of Soil Science and Agricultural chemistry, SKUAST-K, ²Biofertiliser Research Laboratory, Faculty of Agriculture, SKUAST-K

Soil is the world's most vital component for food and fiber production: preservation of this critical natural resource is paramount for protecting the environment, and ensuring that current and future populations are healthy and well-fed. Soil quality is the critical component of sustainable agriculture. Soil quality can be conceptualized as a three-legged stool, the function and balance of which requires an integration of three major components sustained biological productivity, environmental quality, and plant and animal health. The concept attempts to balance multiple soil uses (e.g., for agricultural production, remediation of wastes, urban development, forest, range, or recreation) with goals for environmental quality. Many decades of research have consistently shown that the best means of improving and restoring soil quality and productivity is by proper and regular additions of organic materials mainly through the use of crop rotations, cover crops, crop residues, animal manures, composts, and reduced tillage. Soil organic carbon (SOC) is the most often reported as the most important indicator of soil quality and agronomic sustainability because of its impact on other physical, chemical and biological indicators of soil quality. Often the topsoil is lost at a rate that far exceeds the capacity of natural processes to regenerate it. With soil degradation, there is a concomitant decline in soil quality, i.e., the soil's capacity to produce healthy and nutritious crops, resist erosion, and reduce the impact of environmental stresses on plants. Society is demanding solutions from science. Simply measuring and reporting the response of an individual soil parameter to a given perturbation or management practice is no longer sufficient. The soil resource must be recognized as a dynamic living system that emerges through a unique balance and interaction of its biological, chemical, and physical components.

Key words: Agricultural sustainability, soil organic carbon, environment quality.

BIOENERGY SIMPLER WAY TO ENERGIZE AGRICULTURE**AYUSHRI CHAUHAN, GIRISH TIWARI***Department Of Agriculture, Shri Guru Ram Rai University, Dehradun, 248001.*

Bioenergy is renewable energy made available from material derived from biomass which include animal, plant and their by-product. Biomass is any organic material that store sunlight in the form of chemical energy. Biomass, when burned produces heat that is directly turned into biofuel. Biofuel when compared to fossil fuel does not release CO₂ and are present in abundant sources. Biofuel are converted into biodiesel and bioethanol which are alternates for diesel and petrol. Many Bioenergy routes can be used to convert a range of biomass sustainable seed bags such as wood, straw and waste into a final energy product. The Bioenergy industry now represents a major market not only for established crop but for novel crop and a variety of waste product. Bioenergy cuts down the transportation cost and in addition to this, fuel cells have a power generating application that is available for electricity. Heat producing biofuel with a blend of biodiesel will reduce the emissions of both nitrogen and sulphur dioxide. Currently, 6% of the good energy supply is bio methane and 19% of the electricity we supply is generated from Bioenergy. Biofuels can help to clean up oil spills and grease. Biofuel as Bioenergy are seen as the alternate which can replace all human energy sources. Bioenergy is already making a substantial contribution to meeting global energy demand.

BIO-EFFICACY OF VARIOUS HERBICIDES AGAINST MIXED WEED FLORA OF WHEAT CROP.**B.K MISHRA,¹ A.K SINGH², MITHLESH KUMAR PANDEY³ AND ARVIND SINGH⁴**

Department of Agriculture, Innocent Hearts Group of Institution, Loharan, Punjab., 2- Department of Agronomy, T.D.P.G College Jaunpur U.P. , Department of Agriculture, Innocent Hearts Group of Institution, Loharan, Punjab., Department of Entomology : SVPUA&T, Meerut (UP) 250110

A Field experiment was conducted during rabi season of 2015-16 on sandy loam soil at Agricultural Research Farm (Pili Kothi) of Agronomy Department, Tilakdhari Post Graduate College, Jaunpur (U.P) to evaluate the effect of different herbicides (alone and mixtures) against complex weed flora in wheat crop. The experimental field was mainly infested with *Chenopodium album*, *Anagallis arvensis*, *Parthenium hysterophorus*, *Cynodon dactylon* and *Cyperus rotundus* during the study period. The experimental result indicated that the post-em application of clodinafop + metsulfuron at 0.04 + 0.005 kg a.i/ha was most effective herbicides and recorded minimum density and dry weight of total weeds, without any phytotoxicity symptoms on the crop. Significantly higher values of wheat yield, yield attributes and growth parameters was recorded in clodinafop + metsulfuron at 0.04 + 0.005 kg a.i/ha treated plot at 33 DAS when compared with unweeded control. Weed growth suppression effect of clodinafop + metsulfuron at 0.04 + 0.005 kg a.i/ha resulted 80.8 per cent higher economic yield of wheat over unweeded control and remain statistically similar with weed-free condition in respect to grain yield of wheat crop.

Keywords:- Herbicide, wheat, weed management

USE OF PLANT HEALTH CLINIC LABORATORY IN IDENTIFYING AND SOLVE PESTS AND DISEASES PROBLEMS OF MAJOR CROPS**¹B.L. MEENA, ²R.R. MEENA, ¹K.C. MEENA, ³C.B. MEENA AND ¹RAMASREY**

¹Krishi Vigyan Kendra, Sawai Madhopur (AU, Kota), Rajasthan, 322 001, India, ² Krishi Vigyan Kendra, Kota (AU, Kota), Rajasthan, 324001, India, ³ Agriculture Research Station, Ummedganj, Kota (AU, Kota), Rajasthan, 322 001, India

The main objective of Krishi Vigyan Kendra (KVK,s) is to help the farmers in the field of agriculture and allied sectors. Jhalawar district is mainly mandarin, coriander, garlic, soybean, wheat, fenugreek growing area. During the last 3 years i.e. from 2013-14, 2014-15 and 2015-16, a record of all the visiting farmers was maintained in the Plant Health Clinic Laboratory (PHCL) at the KVK, in which complete details of the farmer with address and contact number was maintained. Similarly, the purpose of visiting KVK was recorded date wise by the KVK and at the end of each month, a summary was prepared and analysed for severity of the attack of insect pest and diseases. During these three years, total 2657 problems related different pests and diseases of crops were recorded. Farmers belong to various agro-ecological situations of the district. It is clearly indicate that most of the problems such black fly, fruit fly, sooty mould, bark eating caterpillar was related to mandarin (27.17%) during the whole year mainly July month followed by coriander' stem gall disease (18.86%) during winter season after mid December to last week of January. Most of the farmers (22.00%) started contact to KVK about the management of black fly and fruit fly in mandarin during pre monsoon in the month of June followed by August, December, April, respectively. Frequently visit of the farmers in the KVK campus in each month indicates that this crop is being attacked by insect pests and diseases during the round of year. Regarding coriander crop, 98.00 per cent farmers visited KVK during the month of January and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

February for the management only stem gall disease. Weather condition during this period was favorable for the disease i.e. continuous low temperature and high humidity. During 2014-15, in the month of January, continuous rainfall, high humidity and cloudy weather are most favorable condition for the severity the stem gall disease. Although vegetable crops like tomato, chilli, brinjal, bhindi, cucurbits, cauliflower, cabbage were more prone to the attack of insect pest rather than disease as the 25.40 per cent farmers visited to know about the management of insect pest and diseases. Other crops like garlic (4.97%), onion (2.82%), soybean (3.88%), blackgram & greengram (2.22%), gram (2.15%), mustard (0.83%), other fruits (6.89%) and other medicinal plants (2.97%) were also taken samples and solved their problems. It was also revealed that the crop was prone both to the attack of insect and diseases. Electronic microscope attached laptop-LED programme, posters, charts, photographs, insect disease specimen collection, various modern plant protection equipments, botanicals and bioagent products like pheromone traps, low cost bottle fruit fly trap, light trap, NPV, *Trichoderma*, *Trichogramma* card, NSKE, neem oil, *Beauveria* are helpful to diagnosis and solve the pest and disease problems in the laboratory. As krishi Vigyan Kendra imparts short duration trainings, diagnostic visit alone & allied departments, timely survey of pest and disease to manage and awareness among the farmers, It can be concluded that KVK staff and other line departments should provide trainings related to the above mentioned technological problem in a particular month.

DETECTION OF ANTIFUNGAL EFFICACY OF WEED EXTRACTS AGAINST *COLLETOTRICHUM CAPSICI* CAUSING ANTHRACNOSE OF CHILLI

*B. P. BIRARI, K. E. SHEWALE AND K. K. SURYAWANSHI

Department of Plant Pathology, Panjabrao Deshmukh Krishi Vidyapeeth, Akola (M.S.) 444 104, Department of Entomology, J. N. K. V. V., Jabalpur

The pathogenic ability of *Colletotrichum capsici* was proved under detached chilli fruit. Among all the solvent extracts, methanolic extract of *Psoralea corylifolia* had potential antifungal activity against *Colletotrichum capsici*. *P. fluorescens* and *T. viride* were found compatible with each other and also with methanolic extract of *Psoralea corylifolia*. Different solvents viz., acetone, ethanol, methanol and chloroform were tested to compare the maximum extraction yield from four different plants. Methanol was found useful for getting highest per cent extraction yield. Methanolic extracts of *Psoralea corylifolia*, *Datura* sp. and *Lantana camera* were selected for chromatographic analysis on the basis of *in vitro* growth inhibition assay against tested pathogen. This method was used to study the preliminary phytochemicals present in methanolic extract of three different plant extract, while thin layer chromatography was used for separation of different compounds present in crude methanolic extract of *Psoralea corylifolia*, *Datura* sp. and *Lantana camera*. All the plants methanolic extracts showed presence of saponins, fixed oils, flavonoids, tannins and phenolic compounds. Among 31 different combinations of solvent systems used under experiment, Toluene : ethyl acetate : methanol (24:5:1.5), Toluene : ethyl acetate : water (10:10:2) and Toluene : ethyl acetate : water (12:4:2) were effective for good separation of methanolic extract of *Psoralea corylifolia*, *Datura* sp. and *Lantana camera* respectively by thin layer chromatography. In detached chilli fruit bioassay treatment with *P. fluorescens* (culture filtrate @ 0.5%) + *T. viride* (culture filtrate @ 0.5%) + methanolic extract of *Psoralea corylifolia* 2% was proved effective to reduce intensity of anthracnose of chilli caused by *Colletotrichum capsici*.

ECOFRIENDLY OPTIONS FOR SUSTAINABLE AGRICULTURE

BABITA BHATT

Department of Entomology, College of Agriculture, Govind Ballabh Pant University of Agriculture & Technology, Pantnagar, Uttarakhand

Sustainable agriculture is a system of agriculture that is ecologically, economically, and socially viable, in the short as well as long term. There are many reasons (droughts, challenges in energy demand, decreasing soil productivity) why we need to change from a conventional agricultural system to one that is sustainable. In addition, the success of high yielding varieties of wheat and rice that ushered in the "green revolution" to feed the increasing population was partially under the protection umbrella of pesticides. But, the over-reliance on the use of synthetic pesticides in crop protection programs around the world has resulted in disturbances to the environment, pest resurgence, pesticide resistance, and lethal and sub-lethal effects on non-target organisms. These side effects have raised public concern about the routine use and safety of pesticides thus, leading to the development of an alternative Ecofriendly Pest Management approach which is based on an understanding of pest ecology and relies on a range of preventive tactics and biological control to keep pest populations within acceptable limits. Ecofriendly Pest Management options may be considered proactive or reactive. Proactive options, such as crop rotations and creation of habitat for beneficial organisms, permanently lower the carrying capacity of the farm for the pest. The carrying capacity is determined by factors like food, shelter, natural enemy complex, and weather, which affect the reproduction and survival of a species. Proactive strategies involve cultural control (manipulations of the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

agroecosystem that make the cropping system less friendly to the establishment and proliferation of pest populations). The second set of options is more reactive (involve all the measures that are taken after the emergence of the pests in the field). This simply means that the grower responds to an economically damaging population of pests, with some type of suppressive action. Reactive methods generally include inundative releases of biological control, mechanical and physical control, and chemical control (use of reduced risk pesticides). The population now demands the organic food or the residue free food which is possible by limiting use of high risk pesticides. Long term pest management solution to pest problem can only be sought by re-structuring and managing ecosystem in such a way that enhances the ability of inbuilt mechanisms of plants to resist insect damage. This will reduce the pesticide usage; will improve the soil productivity thus, leading to sustainable agriculture and the sustainable planet as a whole.

Keywords: Ecofriendly, Options, Sustainable, Agriculture

ECO-FRIENDLY MANAGEMENT OF ROOT-KNOT NEMATODE (*MELOIDOGYNE INCOGNITA*) IN SUSTAINABLE AGRICULTURE

BABITA KUMARI, VINOD KUMAR, K. K. VERMA

Department of Nematology, CCS Haryana Agricultural University, Hisar-125004

The need for alternatives to nematicides has stimulated research focusing on sustainable and eco-friendly management of plant parasitic nematodes. Root-knot nematode, *Meloidogyne* spp., are the major plant parasitic nematodes attacking most of the crops. Nematicides are very much effective but their unsafe use may result in acute poisoning and deaths are a problem especially in developing countries. The nematocidal activity of neem could be due to any of the several known biologically active principles it contains, such as nimbin, nimbidin, thionemone, kemferol, azadirachtin, etc., which are nematocidal in nature. The culture of *M. incognita* was maintained on okra plants in infested soil pots inside the screen house. All the concentrations of the aqueous extracts from fresh leaves of *Eucalyptus globulus* (20% w/v) caused the mortality of second stage juveniles of *Meloidogyne incognita* whereas the more mortality occurred in 1:5 concentration and the least in 1:80 concentration. Juvenile mortality decreased with an increase in the dilution of all the extracts. As an increase in exposure time, juvenile mortality was also increased. This study also revealed that *Azadirachta indica* leaves @ 30 g/kg of soil in pots when incorporated, improves the plant growth and reduced the *M. incognita* infestation in okra. Moreover, *E. globulus* and *A. indica* can be used as an alternative in eco-friendly management of root-knot nematode.

Keywords: *Meloidogyne incognita*, *Azadirachta indica*, *Eucalyptus globules*, Eco-friendly management.

AN ECONOMICS REVIEW ON SUSTAINABLE AGRICULTURE DEVELOPMENT

BABITA KUMARI¹, THANUJAP³, JUGALKISHOR SILLA², BIMLA²

Department of Agricultural Economics, COA, SKRAU, Bikaner¹, Department of Agricultural Economics, RCA, MPUAT, Udaipur³, Division of Plant Pathology, Rajasthan Agricultural Research Institute, Durgapura²,

World population continues to grow, much more effort and innovation will be urgently needed in order to sustainably increase agricultural production, improve the global supply chain, decrease food losses and waste, and ensure that all who are suffering from hunger and malnutrition have access to nutritious food. Many in the international community believe that it is possible to eradicate hunger within the next generation, and are working together to achieve this goal. Extreme poverty and hunger are predominantly rural, with smallholder farmers and their families making up a very significant proportion of the poor and hungry. Thus, eradicating poverty and hunger are integrally linked to boosting food production, agricultural productivity and rural incomes.

Land, healthy soils, water and plant genetic resources are key inputs into food production, and their growing scarcity in many parts of the world makes it imperative to use and manage them sustainably. Boosting yields on existing agricultural lands, including restoration of degraded lands, through sustainable agricultural practices would also relieve pressure to clear forests for agricultural production. Wise management of scarce water through improved irrigation and storage technologies, combined with development of new drought-resistant crop varieties, can contribute to sustaining dry lands productivity. An increase in integrated decision-making processes at national and regional levels are needed to achieve synergies and adequately address trade-offs among agriculture, water, energy, land and climate change. Given expected changes in temperatures, precipitation and pests associated with climate change, the global community is called upon to increase investment in research, development and demonstration of technologies to improve the sustainability of food systems everywhere. Building resilience of local food systems will be critical to averting large scale future shortages and to ensuring food security and good nutrition for all.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**STUDIES ON VEGETATIVE PROPAGATION TECHNIQUES IN CITRUS (*CITRUS LIMON* BURM.)****BABLOO PATEL*, SATYA PRAKASH*, PUSHKAR DIXIT*, SHARDULYA SHUKLA* AND SONU KATIYAR*****Department of Horticulture* and Department of Plant Pathology**, SVP University of Agriculture and Technology, Meerut, 250 110 (UP).*

Various propagation studies have been carried out in different species of citrus. The effect of different concentrations of Indolebutyric acid (IBA) and growing conditions on adventitious root formation in stem cutting of Kagzi-lime. Properly prepared cuttings of about 22-24 cm length in the month of June were treated with different concentrations of IBA viz., 500, 1000, 1500 ppm and planted in 3 different conditions, namely, open area, under partial shade and under low cost polyhouse. The cuttings treated with IBA 500 ppm performed best in all aspects, i.e., root formation, root length, root thickness and leaf sprouting in shoot. Among the growing conditions, open area growing condition was found effective in increasing the success rate of the cuttings. The performance of all the rooting parameters was found better under polyhouse condition. Effect of different growing media, hormonal treatments and growing seasons on shoot and root characters and survival percentage of cuttings of lemon cv. Plant Lemon-1. Pooled data of two season (rainy and spring) has shown that soil + sand + FYM growing medium resulted maximum length of sprouts and average number of leaves per cutting, whereas maximum diameter of shoot and length of longest roots were recorded with soil + coco peat based medium. The result of the study also revealed that average diameter of root was higher in soil + coco peat and soil + FYM medium. Maximum survival percentage of cuttings was noted with soil + sand + FYM. IBA (500 ppm) was found superior in respect of all growth parameters except for root diameter which was found to be highest with IBA + NAA (500 ppm each). In respect of season of planting of cutting, rainy season was found superior over spring season for all shoot and root characteristics.

Keywords: citrus, propagation, indole butyric acid, polyhouse, survival percentage, growing media and growing season.

EMERGING DRONE TECHNOLOGY IN SUSTAINABLE AGRICULTURE AND SMART CROP FARMING**BABULAL CHOUDHARY, UNDER SUPERVISION OF PROF. PRIYANKER RAHA***Soil science & agricultural chemistry at Institute of Agricultural sciences, BHU VARANASI*

The use of Drone system in sustainable Agriculture becoming most effective and popular. The continuous growth of the population together with the decreasing of resources at disposal poses the problem of smart usage of resources. It is important especially in the field of food production & soil exploitation. The common methods used in agriculture to analyses and assess the correct production and usage of resources employs optical and multispectral techniques applied to photos captured from satellites. These techniques allow to assess the light absorption from the leaf displays the presence of chlorophyll. This is a critical and important things since the results of these phase will affect the decisions of interventions on the feeding of the soils, the protection from insects/fungi. In remote sensing for surveying and mapping of the soil and plant DRONE becoming most effectively used. It can be use in irrigation application, assessing crop health by determining crop stress, protecting wild life by tracking. For this, draw field borders for flight pattern. This map is the key to boosting yields, cutting costs, and driving your business forwards. It highlights exactly which areas of crop need closer examination. It most effectively using in crop monitoring, soil & water analysis, planting & spraying. Drones are however becoming much more affordable as the technology advances and key components become commonplace in other devices such as Smartphone.

Key words: 1. Assess the correct production of crops, 2. Uses multispectral techniques, 3. Crop stage and soil mapping and surveying, 4. Soil and water analysis

CLOUD SEEDING**BAL MANOHAR* AND SUSHMITA***Bihar Agricultural College, B.A. U Sabour, Bhagalpur, Bihar*

Natural disaster have a worse impact on the society linked sectors like agriculture, animal husbandry, fisheries, forestry, biodiversity (both land and ocean), water resources and health. In order to minimize the losses due to weather hazards, weather modification strategies can be adopted. There are several methods to modify the existing weather. The most popular method among them is cloud seeding. Cloud seeding is defined as the introduction of a seeding agent into suitable clouds to encourage the formation and growth of ice crystals or raindrops, which in turn enhance the precipitation from the clouds (Denholm, 2010). Cloud seeding provides condensation nuclei for the initiation of collision-coalescence process in warm cloud and ice crystal process in cold clouds (Hess, 1974). Based on the seeding material used, cloud seeding is classified into glaciogenic and hygroscopic. Glaciogenic seeding is done in cold clouds using ice forming substances like silver iodide and dry ice. Hygroscopic materials like sodium chloride and calcium chloride are used as seeding agents in warm clouds. These materials are released through ground based or airborne systems. There are two types of seeding done by aircraft viz., base seeding and top seeding. For delivering the agents, burn-in-place or ejectable flares are used (Sharma, 2009). The

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

principle of cloud seeding was discovered by Vincent J. Schaefer and Irving Langmuir in 1946 at General Electric Laboratories, New York. Cloud seeding operations in India were started in 1951. At global level, China is the leading country in cloud seeding operations, followed by Russia and Israel. Cloud seeding is also intended for dissipation of fog, hail damage suppression, snowfall augmentation, cyclone modification and lightning suppression (Mahi and Kingra, 2007). However, majority of operational projects are focused on rainfall enhancement. According to Venkataraman and Krishnan (1992), cloud seeding cannot be done in all types of clouds. Best suited clouds for cloud seeding operations are identified using ground based radar and aircraft systems. Precipitation monitoring is also done by radar, which is supplemented by ground level rain gauge measurements. The frequency of weather hazards like occurrence of droughts is likely to increase under the projected climate change scenario. Therefore, there is a need to strength then experiments on cloud seeding as a proactive measure to combat ill effects of drought and to enhance water resources.

FOLIAR SPRAY OF MICRONUTRIENTS IN OILSEEDS CROP**BANDANA BHATT, AJAY KUMAR, ANUPAMA RAWAT****Department of Agronomy, College of Agriculture, Govind Ballabh Pant University of Agriculture and Technology, Pantnagar*

In the agricultural economy of India, oilseeds are important next to food grains in terms of area, production and value. The demand of vegetable oil in India is very high due to which there is a need to increase the home production of oilseeds crops. One of the reasons for low yield is nutrient deficiencies. Availability of nutrients in optimum amount is an important factor which influence crop growth yield. Micronutrients serve as a best alternative to increase the oilseed production. Micronutrients are elements that are essential for plant growth but are required in much smaller amount. Micronutrients are involved in metabolic and cellular functions. Micronutrient plays a vital role in Oilseeds crops which includes protein synthesis, involved in nitrogen assimilation, sulphur metabolism, phytohormone biosynthesis, and stress reactions, transport of sugars, respiration, RNA and carbohydrate metabolism, and the metabolism of plant hormones. Recently, foliar application of nutrient has become an important practice in crop production. Nourishment of plant through leaves is considered as more efficient than root absorbance during later stages. However, the wastage of nutrients can be minimised by foliar applications of dilute solution of nutrients to supplement the basal applications which have been shown to be effective and economical in some crops.

Keywords: foliar spray, micronutrient, deficiencies

SOIL ENZYMES: MAJOR COMPONENT IN MAINTAINING SUSTAINABILITY OF CROPPING SYSTEM.**BANDANARANI BARIK, MONALISA SAHOO, RESEARCH SCHOLAR, DEPARTMENT OF AGRONOMY***Institute of Agricultural Sciences, Banaras Hindu University, Varanasi, Uttarpradesh-221005*

Soil enzymes play important role in sustainable agriculture. Soil enzymes are the chemicals which are obtained from microbial activity, plant residues, protozoa, termites and other invertebrates. These enzymes take their role in nutrient recycling like carbon, nitrogen, phosphorus and Sulphur recycling. They act as catalysts in starch, lignin, cellulose, chitin and ester degradation which helps in maintenance of soil health and increase in bioavailability of different nutrient. But there are different factors affecting soil enzyme activity such as soil temperature, soil water content, soil type, agronomic management practices, pesticide and fungicide content. Farm yard manures and other organic manures enhance the activity and availability soil enzymes. Soil under legume based cropping system enhances nitrogen availability to the succeeding crop by biological nitrogen fixation and enhanced enzymatic activity due higher microbial count. it can also reduce toxic material or toxic plant exudates which will increase the soil fertility by maintaining proper soil health. Assays based on substrate-induced respiration have been developed to measure enzyme activity. In this method, a substrate is added to soil, and production of CO₂ or consumption of O₂ is measured. Temporal and special studies on soil enzymes activities will be helpful to know the factors controlling enzymes activities so that optimal conditions for the soil enzymes activities can be determined. Soil enzyme profiling under different cropping systems and management practices can help in understanding correlations between soil enzymes activities and productivity and soil health of the ecosystem.

Key words-soil enzymes, microbial count, nutrient recycling, cropping system.

COMBINING ABILITY ANALYSIS FOR SEED COTTON YIELD AND ITS ATTRIBUTING TRAITS IN UPLAND COTTON (GOSSYPIUM HIRSUTUM L.)**BANKARA. H.*, MADANKAR K. S., K. S. NIRANIA AND SAGAR***Department of Genetics and Plant Breeding, CCSHAU, Hisar-125004*

The present investigation aims to estimate the general combining ability of the parents and specific combining ability of Gossypium hirsutum hybrids for seed cotton yield and its attributes viz., days to first flower (earliness), number of bolls per plant, boll weight, plant

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

height, number of monopodia and number of sympods per plant. Five females crossed with ten testers in line x tester mating fashion resulting 50 hybrids were obtained. Fifty hybrids along with their 15 parents and one standard check were raised during kharif 2016-17 in a randomized block design with three replications at CCS HAU, Cotton Research Station, Sirsa. The study revealed that Gregg 45, MESR-17 and SR-38 among the males while, the H1300 and H1098i among females were found to be good general combiner with highest per se performance for all the traits studied. Among the crosses, H1117 X LRA 5166 (poor x poor GCA), H1226 X SR-38 (good x good GCA), H1098i X PUSA 31 (good x good GCA) and H1300 X AVB SM-277 (good x poor GCA) were recorded high heterosis with good SCA effects for seed cotton yield and its yield attributes in desirable direction. The magnitude of sca variance was greater than gca variance for all the traits except plant height, indicating that the both additive as well as non-additive gene action responsible for SCA effects with the preponderance of non-additive genetic variance for inheritance of these characters.

Key words: *Gossypium hirsutum*, Line X Tester analysis, GCA and SCA variance, seed cotton yield.

USE OF BIOCHAR IN AGRICULTURE**BARKHA**

Ph. D. scholar, Dept. of Agronomy, Navsari Agricultural University, Navsari (Gujarat)

Soil organic carbon is an extremely valuable natural resource. Considering the global climate change, the SOC stock must be restored, enhanced, and improved. Soil C sequestration is the process of transferring CO₂ from the atmosphere into the soil through plants, plant residues and other organic solids, which are stored or retained in the soil as a part of the soil organic matter. The application of biochar to the soil is proposed as a novel approach to establish a significant long-term sink for atmospheric carbon dioxide in terrestrial ecosystems. The term 'biochar' denotes black carbon formed by the pyrolysis of biomass, *i.e.*, by heating biomass under oxygen-free or stress environment, so that it is not subjected to complete combustion. Biochar, due to its aromatic structure and long mean residue time in the soil (more than 100 years) has the potential for long-term carbon sequestration in the soil. Biochar decomposition rate is slow in the soil, which indicates that it could be the possible answer to mitigation of elevated atmospheric CO₂. It has been found that addition of biochar along with chemical fertilizers produced significant increase in crop yield. Other potential benefits listed in literature include carbon sequestration by the natural process of photosynthesis, reduction of CO₂, N₂O and CH₄ emissions from soils, net production of energy in form of bio-energy, increase in soil fertility and microbial activity in the soil, improvement of water retention capacity in the soil, improvement of cation exchange capacity of the soil, improvement of durability of soil aggregates and reduction of erosion and nutrient leaching, reduction in need of fertilization and decreased dissipation rate of herbicides in the soil. Thus, use of biochar in agriculture can mitigate the increasing CO₂ concentration in the environment provided its rate of application and mechanism of action are fully understood.

GENETIC ENGINEERING OF TOMATO (*LYCOPERSICON ESCULENTUM*) PLANT USING ANNEXIN GENE THROUGH AGROBACTERIUM MEDIATED TRANSFORMATION**BASANT KUMAR SHARMA¹ AND M. SHAMSUL ISLAM²**

P.G. Department of Biotechnology, Magadh University, Bodhgaya, Bihar (India) -824234, P.G. Department of Botany, Magadh University, Bodhgaya, Bihar (India) -824234

Drought and high salinity are two major abiotic stresses that significantly affect agricultural crop productivity worldwide. Annexins are multigene family that plays an essential role in plant stress responses and various cellular processes. The present study involves the development of genetically engineered tomato, (*Lycopersicon esculentum*) plant with annexin gene. *E. coli* bacteria (resistant to kanamycin) carrying pGPTV/ annexin, *E. coli* carrying helper plasmid pRK2013 and *A. tumefaciens* (MTCC431 strain) carrying disarmed Ti plasmid (resistant to Streptomycin) were used for tri-parental mating. The annexin gene construct was transferred into plant genomic DNA by using leaf disc preparation, co-cultivation and selection media transfer. The selection media consists of Kanamycin, Augmentin and Cefatoxime. Leaf disc containing gene construct survives on selection media and were allowed to grow in the form of callus that is regenerated into transgenic plantlets, indicating the presence of gene of interest, which was further confirmed by extraction of genomic DNA and PCR analysis. Study revealed that Agrobacterium-mediated transformation in tomato was successful method for transfer of annexin gene. The methodology may be used for the commercial production of transformed tomato plant with salt and Drought tolerance character.

Key words: *A. tumefaciens*, *Lycopersicon esculentum*, Annexin gene, *E. coli* DH5α, pUC119, pGPTV,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**DOUBLING FARMERS' INCOME: WAY FORWARD****BHAGWATI BARANDA * SMARTISHREESAHO * PRIYANKAADLAN ****Department of Plant Breeding and Genetics, *College of Agriculture, S.K.R.A.U-Bikaner, Rajasthan -334 006(India), **GBPUAT, Pantnagar, Uttarakhand -263145 (India)*

The will of the present Government to double the incomes of farmers by 2022 as announced by the Honorable Finance Minister during his Budget Speech on 29 February 2016 has been greeted with less of optimism and more of skepticism by economists and other columnists. Do we have evidence of income growth in past decades and if so what does it tell us about the possibility of doubling incomes? Is the 7-pronged strategy to achieve the doubling as announced by the honorable Prime Minister enough? If not, what other initiatives are needed? This issue of Rural Pulse discusses some of these questions. Pulses as a candidate crop, contributes immensely towards doubling farmers' income through better package of practices, diminishing cost of production, efficient marketing networks and successful technology delivery mechanisms by giving emphasis on scientific evidences suggest that existing vast gap grain yield of pulses can be bridged with site-specific technological modules including appropriate varieties as climate resilient production technologies backed with strong research outputs in pulses can contribute towards doubling the farmers' income.

Key word: pulse, innovation tech., rural development, innovation achievement,

PRECISION NITROGEN MANAGEMENT IN RICEBASED CROPPING SYSTEM**BHAGYASHREE PHOGAT¹, AKSHAY KUMAR YOGI²***¹ICAR-Indian Agriculture Research Institute, Jharkhand, India, ²ICAR-Indian Agriculture Research Institute, Assam, India*

The blanket recommendation of nitrogen (N) in ricebased cropping system leads to low yield, N use efficiency (NUE) and green house gases emission. It has been reported that N recovery by irrigated rice in onfarm experiments is only 31% with farmer fertilizer practices (FFP) in South Asia. Therefore, there is need to synchronise N management considering fieldtofield N variability in soil supply and demand. The precision N management could be one of the strategies to enhance productivity and resourceuse efficiency in rice based system. It considers N deficiency or excessiveness exists within the field at particular time, and makes adjustment in N application to match these locations differences. This strive to enable farmers to adjust fertilizer use dynamically to make up the deficit in N needs between that required by a crop and nutrient supply from naturally occurring indigenous sources. The sitespecific N management (SSNM) approach could be one of the approach which reported to enhance system productivity (15-35%) and response to yield increased (12-20%) in ricewheat cropping system. Leaf color chart (LCC), soil plant analysis development (SPAD) meter, Green Seeker and Nutrient expert/manager are the most important tools available for tailoring the N in rice crop. N application through LCC saved 21.6% of applied N compared to FFP in 461 on-farm experiments in Punjab. N application through field specific N management could enhance the N recovery up to 40% in South Asia. Besides, higher yield and NUE, annual N losses also get reduced by using nutrient expert based split N application in ricewheat cropping system. It can be concluded that precision N management can provide new possibilities for achieving higher NUE and yields in ricebased systems besides addressing the environmental problems in near future.

Key Word: Green Seeker, Leaf color chart, Nitrogen, Nutrient Use Efficiency, Productivity, SPAD, SSNM

AGRICULTURAL MECHANIZATION IN INDIA: WITH REFERENCE TO SMALL AND MARGINAL FARMER.**BHARAT D.V., SAKET KUSHWAHA, SARTHAK GHIMIRE, PRABIN KARKI***Department of Agricultural Economics, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005, India*

Mechanization is must for the agricultural growth in the country. Food and fiber production in the country like India depends upon the small and marginal farmers. 67% of farmers own land holding less than 1.0 ha. But these farmers merely own agricultural machinery like spade and hoe making their agricultural activities labor intensive and costlier. It is reported that during 2003-13, small farmers with up to 1 ha of landholding were able to increase their income by 50%, whereas the farmer with more than 10 ha was able to double income. This has led to the income inequality among the farming community. With the increase in mechanization in agriculture, we can have decreased production cost and, also these farmers can have increased income by involving in off-farm activities. A recent survey by NABARD shows that only 5.2 % of farmers own a tractor and 1.8 % owns power tiller. Similarly, access to drip irrigation and sprinkler was limited to 1.6 % and 0.8% of farming households respectively. Although there are various developments in the design and commercialization of technologies for small farmers, reports from India is not satisfying in the light of government's plan of doubling farmer's income. So, it is must for the related stakeholder to revise policies for agricultural machinery with special focus to the farmers with less farm holding. This paper examines the status of agriculture mechanization in India with the special focus on small and marginal farmers, and makes necessary recommendations.

Key words: Agricultural Mechanization, Indian Agriculture, Small and marginal farmer, Farm income

EFFECT OF INTEGRATED NUTRIENT MANAGEMENT ON ECONOMICS OF WHEAT (*TRITICUM AESTIVUM* L.)-PEARL MILLET CROPPING SYSTEM**BHAWANA SAHARAN¹, R.S. YADAV², JITENDRA KUMAR VERMA³, RAKESH KUMAR⁴, SOMA DEVI⁵ AND HANSRAJ SHIVRAN⁶***Based on part of Ph.D thesis of first author, submitted to S.K.R.A.U., Bikaner. 2-HOD, Department of Agronomy, 3,5,6- Dept. of Agronomy, S.K.R.A.U., Bikaner (Raj.) and 4- GBPUAT, Pant Nagar (Uttarakhand)*

A field experiment was conducted at Bikaner to evaluate the effect of integrated nutrient management on wheat (*Triticum aestivum* L.)-pearl millet cropping system during *rabi* and *kharif* seasons of 2014-15 and 2015-16. Experiment was laid out in a split plot design with three replications comprising different treatment combinations *i.e.* control, 50%, 75% and 100% RDF, 50% RDF + FYM (5 t ha⁻¹), 75% RDF + FYM (5 t ha⁻¹), 100% RDF + FYM (5 t ha⁻¹), 50% RDF + FYM (5 t ha⁻¹) + *Azotobacter* + PSB, 75% RDF + FYM (5 t ha⁻¹) + *Azotobacter* + PSB and 100% RDF + FYM (5 t ha⁻¹) + *Azotobacter* + PSB, applied in wheat as main plots and 3 fertility levels (control, 50% and 75% RDF) as sub plot in succeeding pearl millet comprising a total of 30 treatment combinations. Incorporation of INM treatments mainly as 75% RDF + 5 t FYM ha⁻¹ + *Azotobacter* + PSB in wheat and direct incorporation of fertilizers (*i.e.* 75% RDF) to pearl millet significantly increased the yield attributes, yield and monetary returns of wheat- pearl millet cropping system. It was revealed that combined application of different nutrient management treatments in wheat-pearl millet cropping system will help in improving farmer's income rather than single application of nutrient sources. Significantly highest net returns during individual years 2015, 2016 and in pooled mean analysis 56682, 68662 and ` 62672 ha<sup>-1</sup> with B:C ratios 2.02, 2.22 and 2.12, respectively were fetched under 75% RDF + 5t FYM + *Azotobacter* + PSB applied in wheat followed by 100% RDF + 5t FYM + *Azotobacter* + PSB and net returns under 75 % RDF in pearl millet were 47449, 57652 and ` 52551 ha⁻¹ and B:C ratios 1.87, 2.05 and 1.96, respectively were obtained under wheatpearl millet cropping system.

Keywords: INM, RDF, FYM, Nutrient sources and Monetary returns.

EVALUATION OF SENSORY QUALITIES OF ENCAPSULATED HYDROLYZED VEGETABLE PROTEIN**BHAWNABISHT¹, U.C LOHAN²***Department of Post-Harvest & Food Engineering, G. B. Pant University of Agriculture and Technology, Pantnagar- 263145, Uttarakhand*

Hydrolyzed Vegetable Proteins (HVP) have been well known to elevate the flavor of foods. However, most of the research has remained concentrated on soybean proteins, in spite of its allergenicity and high cost. Moreover, its flavor have never been attempted to be captured using the encapsulation technique. Corn and barley flour were hence selected as substrates for acid and enzymatic hydrolysis to produce acid-HVP (a-HVP) and enzyme-HVP (e-HVP) for the production of flavor enhancer, for their high nutritional content, low cost, non-allergenicity and underutilization in India. Acid hydrolysis was performed followed by neutralization and decolorization with activated charcoal, whereas enzymatic hydrolysis was performed using Trypsin enzyme followed by vacuum filtration. Encapsulation of the a-HVPs and e-HVPs were performed using sodium alginate (2%) as a gel matrix and calcium chloride (2M) as a hardening bath. The encapsulated HVPs, after being incorporated in a commercial peanut dip, were sensorially analyzed by panelists in comparison with a control sample. Physicochemical tests were performed of the developed HVPs (corn, barley) and evaluated for the following factors: pH, specific gravity, sodium chloride content, reducing sugar, α -amino acid content and protein content. Significant results ($p < 0.05$) were obtained (in case of reducing sugar, sodium chloride content and sensory analysis) differentiating the two hydrolysis methods subjected on the substrates. Statistical analysis of the panelists test data showed that the barley flour encapsulated produced a-HVP and e-HVP have been preferred by the panelists due to its low salt content, and had an overall mellow flavor profile as compared to the corn flour encapsulated a-HVP and e-HVP. Hence, Barley flour HVP has the potential to be used as a food additive for flavor enhancement in foods commercially.

Keywords: Hydrolyzed Vegetable Protein, acid hydrolysis, enzymatic hydrolysis, encapsulation, flavor enhancer, food additive.

EVALUATION OF CHRYSANTHEMUM (*CHRYSANTHEMUM MORIFOLIUM* RAMAT.) GENOTYPES FOR FLOWER YIELD AND COMPONENT TRAITS**BHUPENDER SINGH DALAL****Department of Horticulture, CCS Haryana Agricultural University, Hisar-125004*

A field experiment was carried out in the experimental orchard, Department of Horticulture, CCS Haryana Agricultural University in winter season on 30 genotypes of chrysanthemum to estimate the genetic variability, heritability, genetic advance and varietal

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

characterization. The experiment was laid out in Randomized Block Design with three replications. The observations were recorded for plant and floral parameters. The mean performances showed that maximum number of flowers and buds per plant were observed in Anmol. Maximum plant height was observed in Winter Queen, maximum duration of flowering and days to first flower was observed in Autumn Joy. Maximum number of flowers per plant were recorded in Anmol, whereas, minimum in S-30. The highest size of flower and stalk length was exhibited by genotype-149. The maximum fresh weight of ten flowers was recorded in genotype- 26 while dry weight of ten flowers was maximum in Double-1. The genotype Anmol produced highest flower yield per plant followed by genotype 24 while lowest in genotype S-30. It can therefore, be concluded from the present study that there was a significant genetic variability in the chrysanthemum genotypes for various characters and the estimates of genetic variability, heritability, genetic advance and path analysis suggested that for the improvement and development of high flower yielding chrysanthemum genotypes, the characters like number of buds per plant, number of flowers per plant and plant spread should be considered in breeding methodology.

Key words: Chrysanthemum, genetic variability, heritability and flower yield

INTEGRATED EFFECT OF BIO - INOCULANTS, ORGANIC AND CHEMICAL FERTILIZERS ON GROWTH, YIELD AND QUALITY OF OKRA [*ABELMOSCHUS ESCULENTUS* (L.) MOENCH]

BIPUL KUMAR SINGH¹, R.B. VERMA¹, V. K. SINGH¹, MAHENDRA SINGH² AND R. K VERMA³

Department of Hort. (Veg. & Flori), BAC, BAU, Sabour; Department of Soil Science & Agricultural Chemistry, BAC, BAU, Sabour; SMS(Horticulture), KVK, Madhepura, BAU, Sabour

Okra is an important vegetable crop of family Malvaceae, which valued especially for its tender and green fruit. To meet out the demand of increasing population the growers use inorganic nutrient indiscriminately. This left the challenges towards scientists to increase the production of quality food in a sustainable manner. Organic manures and biofertilizers either alone or in integration are the option to improve the soil fertility and productivity in a sustainable manner. The bio-fertilizers are cost effective and produce plant growth promoting hormones, vitamins and amino acids and help to fix atmospheric nitrogen, solubilizing and mobilize phosphorus and translocate the minor elements like zinc, copper etc, to the plants. Keeping these all facts in to consideration, an investigation entitled 'Integrated effect of bio-inoculants, organic and chemical fertilizers on growth, yield and quality of Okra [*Abelmoschus esculentus* (L.) Moench]' was conducted at Vegetable Research Farm, BAU, Sabour to explore the possibilities of best integrated nutrient management option for better growth, yield and quality of okra. The sixteen treatments viz. T₁ (RDF @ 120:60:60 kg NPK ha⁻¹), T₂ (75% of recommended dose of N through chemical fertilizer + 25% N through Vermicompost), T₃ (50% of recommended dose of N through chemical fertilizer + 50% N through Vermicompost), T₄ (25% of recommended dose of N through chemical fertilizer + 75% N through Vermicompost), T₅ (T₁ + *Azotobacter*), T₆ (T₂ + *Azotobacter*), T₇ (T₃ + *Azotobacter*), T₈ (T₄ + *Azotobacter*), T₉ (T₁ + PSB), T₁₀ (T₂ + PSB), T₁₁ (T₃ + PSB), T₁₂ (T₄ + PSB), T₁₃ (T₁ + PSB + *Azotobacter*), T₁₄ (T₂ + PSB + *Azotobacter*), T₁₅ (T₃ + PSB + *Azotobacter*), T₁₆ (T₄ + PSB + *Azotobacter*) were arranged in a randomized block design replicated thrice. Okra variety VNR Super Green was sown in July, 2017 and all the recommended cultural package and practices were followed as per need for healthy crop. Results revealed that the application of 75 % RDN through chemical fertilizer + 25 % N through vermicompost + *Azotobacter* @ 20 g kg⁻¹ of seed + PSB @ 20 g kg⁻¹ of seed (T₁₄) influenced most of the characteristics significantly and recorded the highest values of plant height, number of branches, fruit length, average fruit weight, number of fruits per plant, yield per hectare and B: C ratio (1.62) except number of nodes to first flower appearance, days taken to 50 % flowering and days to first picking, which were minimum however, the microbial load was maximum in T₁₆ treatment, which was statistically at par with T₁₄ and T₁₅. Therefore, the use of 75 % RDN through chemical fertilizer + 25 % nitrogen through vermicompost + *Azotobacter* + PSB is a cost effective and sound integrated nutrient management option for higher growth, yield and quality produce of okra and to improve the fertility status of the soil.

Key words: Integrated, bio-inoculants, inorganic, vermicompost, yield

MICROBIAL CONSORTIA FOR BETTER SOIL HEALTH UNDER NON-LEGUMINOUS PRODUCTION SYSTEM BISWARANJAN BEHERA AND T.K. DAS

Division of agronomy, ICAR-Indian Agricultural Research Institute, New Delhi, 110 012

Soil fertility restoration through the use of chemical fertilizers alone often has negative impact on the complex system of the biogeochemical cycles. Non-leguminous production systems, which contribute maximum to the national food basket, are particularly facing the problem of soil health deterioration owing to mono-cropping and imbalance fertilization. Microbial consortia consisting of two or more microbes, enhances the nutrient availability when inoculated in soil, besides secretion of various plant growth promoting hormones improves soil health. However, major focus earlier remained on single microbe biofertilizer and work on microbial consortia got late moment. Microbial consortia includes plant growth promoting rhizobacteria (PGPR) consortia, biofilm biofertilizer and NPK

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

biofertilizer. It has been observed that seed treatment with *Trichoderma viridae*-*Pseudomonas* biofilm increased germination percentage in cotton (Triveni *et al.*, 2012). Inoculation of blue green algae (BGA) with plant growth promoting rhizobacteria (PGPR) increased nitrogenase activity by 31.4% over sole BGA application in rice (Shahane *et al.*, 2015). *Anabaena-Providencia* inoculation as PGPR increased grain yield of rice by 9% and 14% over sole application of *Anabaena* and *Providencia*, respectively (Meena *et al.*, 2015). Swarnalaxmi *et al.* (2013) observed an increase of 8% and 15% in N uptake and yield in wheat due to the use of cyanobacterial-*Rhizobium* biofilm. PGPR consortium of *Bacillus* sp, *Providencia* sp, *Brevundimonas* sp along with 2/3rd of recommended dose of fertilizer increased Fe, Cu, Mn, and Zn content in wheat grain by 45-143% over the full dose of chemical fertilizer (Rana *et al.*, 2012). Hettiarachchi *et al.* (2014) reported a 19% reduction in nitrate leaching due to application of biofilm biofertilizer. Application of NPK biofertilizer significantly increased total N and available P content in soil over control (Wu *et al.*, 2004). Microbial consortia proved better over single microbe based biofertilizer in improving crop productivity, profitability and soil health. However, its success depends on compatibility of different microbes used. Microbial consortia as a source of nutrient management can combat ill-effects of intensive fertilizer use by reducing environmental trade-offs.

EFFECT OF NITROGEN ON GROWTH PARAMETERS OF FODDER OAT '(*AVENASATIVA* L.)'

BOLLA VENI SATHISH KUMAR¹, RAJ. VIR SINGH², GUNTAMUKKALABABU RAO³

*1*Department of Agronomy, College of Agriculture, Assam Agricultural University, Jorhat, Assam, *Department of agronomy, collage of agriculture, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut 250110 (U.P) INDIA, Department of Agronomy, Assam Agricultural University, Jorhat, Assam*

Plant height of Oat is increased with advancement of crop age and nitrogen level. Plant height was increased significantly upto 160 kg N kg ha⁻¹ at all the growth stages. The increase in plant height with nitrogen level might be related to the availability of more nitrogen for early establishment of enzymes, pigments, and other compounds needed for photosynthesis and other beneficial effects of nitrogen in cell elongation and cell division in meristematic activity as well as inter-nodal expansion. The number of tillers per unit row length increased with crop age only upto 1st cut (60 DAS), and thereafter, decreased progressively under all levels of nitrogen. LAI increased significantly with increasing in nitrogen level from N1 to N5. At 50 % flowering stage LAI increased significantly with increase in levels of nitrogen. In general, dry matter accumulation in plant increased with advancement of crop age and with increasing levels of nitrogen from 0 to 160 kg ha⁻¹. In present study, the increase in dry matter accumulation with nitrogen could be due to increase in specific leaf weight and thickness of young growing leaves with higher crude protein content, higher plant height and more number of tillers. Green forage and dry matter yield significantly with successive increase in nitrogen levels from N1 to N5. Significant increase was observed upto 160 kg N ha⁻¹. Nitrogen application showed the linear influence on green forage yield from 0 to 160 kg ha⁻¹. Plant height, LAI and dry matter accumulation increased with increasing in nitrogen levels. These things directly related with production of green matter.

Key words: Nitrogen and growth

DOUBLING FARMERS' INCOME BY 2022: A CRITICAL APPROACHES

BRIJESH KUMAR AND S K PRASAD

Department Of Agronomy, Institute Of Agricultural Sciences, Banaras Hindu University Varanasi 221005, UP, India

The programme of Doubling Farmers' Income was announced by the Finance Minister, Mr. Arun Jaitley during his budget speech on February 29, 2016. The targeted year that has been set by the govt. for doubling the farmers income is 2022 i.e. from 2015-16 to 2021-22 (Six years) with the objective to double the real income of farmers, not output or value added or the GDP of the agriculture sector. Targeted income includes income from agricultural as well as allied activities. Doubling rural income in nominal terms is possible by increasing agriculture output & minimum support prices (while keeping inflation below 5%), doubling rural income in real terms would be a daunting task considering increasing agriculture output by 12% every year with no additional land likely to be utilized for agricultural activity. However, a long term solution remains faster execution of policies that could develop infrastructure to support irrigation system and reduce the dependency on rains. There is every possibility not only to double the income of farmers through enhancement in productivity, changes in cropping pattern, inspire additional income through many supplementary activities but also provide stability in farmers income. There is need to think beyond food security and give our farmers a sense of income security. It will also attract youth towards farming profession and ease the pressure on non-farm jobs.

AREVIEW- IMPACT OF INTEGRATED NUTRIENT MANAGEMENT ON SOIL HEALTH AND CROP IMPROVEMENT**C.K. DOTANIYA¹, SANDEEP MOHBE¹ AND R.K. DOUTANIYA², H.P. SINGH³**¹Dept. of Soil Science and Agricultural Chemistry, ICAR-Indian Institute of Soil Science Bhopal M.P. 462038, ²Department of Agronomy O.P.J.S. University Churu Rajasthan, ³Sales Officer- EFFCO eBAZAR Anarad Dhar, M.P.

Integrated nutrient management (INM) is not a new concept. It is an age-old practice when almost all the nutrient needs were met through organic sources to supply secondary and micronutrients besides primary nutrients. This may be achieved through combined use of all possible sources of nutrients and their scientific management for optimum growth, yield and quality of different crops and cropping systems. The organic residues that are added to the soil undergo microbial decomposition and in this process, various organic products of decay like polysaccharides are released which act as strong binding agents in the formation of large and stable aggregates which helps to improve the physical properties of the soil (Divya *et al.*, 2013). INM practice was found beneficial for sustaining soil health in terms of build up of organic carbon, macro and micronutrient and enhancing the crop equivalent yield (Vidyavathi *et al.*, 2012). Organic manures acted as nutrient reservoir and upon decomposition produced organic acids thereby absorbed irons are released slowly for the entire crop growth leading to higher plant height. FYM worked as soil conditioner in addition to supplying plant nutrients and resulted in improvement in plant height at different stages of plant growth (Prasad, 1994).

INFLUENCES OF PHOSPHORUS AND SULPHUR ON YIELD ATTRIBUTES OF SUMMER GREEN GRAM (*VIGNA RADIATA* L.) BUNDELKHAND PLATEAU**DS. DHARWE¹, HC. DIXIT¹, CK. DOTANIYA², SANDEEP MOHBE³, RK. DOUTANIYA³**¹Department of Soil Science and agricultural chemistry, Bundelkhand University Jhansi (U.P.) , ³Department of Agronomy, OPJS University Churu, Rajasthan, ²ICAR-Indian Institute of Soil Science Bhopal M.P. 462038

A Pot experiment was conducted to see the Effect of Phosphorus of green gram. Four levels of phosphorus (P) with four levels of sulphur (S) were applied at Agriculture experimental field, Nehru PG collage Lalitpur (U.P.) during 2014-15. Results revealed that application of 40 kg sulphur ha⁻¹ and Phosphorus 90kg ha⁻¹ to the summer green gram crop significantly increased the sulphur and Phosphorus content in seed and straw yield. The interaction effect of P×S on seed and straw production of summer green gram was found also significant and yield was improved by the application of both of these two 90kg P₂O₅ ha⁻¹ and 40kg S ha⁻¹ nutrients as compared to control and but statistically at par with 40 kg sulphur ha⁻¹. The percent enhancement were 6.74, 15.92 and 19.48 in seed and 31.60, 54.50 and 69.71 in straw of green gram due to 10, 20 and 40kg S ha⁻¹ over control respectively.

BIO-EFFICACY AND DISSIPATION PATTERN OF DIFFERENT INSECTICIDES AGAINST DIAMONDBACK MOTH (*PLUTELLA XYLOSTELLA* L.) IN CABBAGE**C.G. SAWANT* AND C.S. PATIL**

All India Network Project on Pesticide Residue, Department of Agricultural Entomology, Mahatma Phule Krishi Vidyapeeth, Rahuri-413 722, Maharashtra, India

Field studies were conducted at farmer's field (at Nandur Madhyameshwar, Tq. Niphad, Dist. Nashik and at Khandgaon, Tq. Sangamner, Dist. Ahmednagar), Instructional Farm, P.G.I, M.P.K.V., Rahuri and laboratory studies were carried out at A.I.N.P. on Pesticide Residue, Department of Agril. Entomology, M.P.K.V., Rahuri. Studies on bio-efficacy revealed that, chlorantraniliprole @ 10 g a.i. ha⁻¹ was found to be the most effective with 91.30 per cent reduction in larval population of *P. xylostella* followed by spinosad @ 17.5 g a.i. ha⁻¹ (87.55%) and flubendiamide @ 18.24 g a.i. ha⁻¹ (86.61%). The maximum marketable yield of cabbage heads (238.15 q ha⁻¹ with 129.23 % increase over control) was obtained from the plots treated with chlorantraniliprole @ 10 g a.i. ha⁻¹ followed by spinosad @ 17.5 g a.i. ha⁻¹ (233.83 q ha⁻¹ with 125.07 % increase over control) and flubendiamide @ 18.24 g a.i. ha⁻¹ (224.98 q ha⁻¹ with 116.56 % increase over control). The highest cost:benefit ratio was registered in the treatment of chlorantraniliprole @ 10 g a.i. ha⁻¹ (1:16.40) followed by flubendiamide @ 18.24 g a.i. ha⁻¹ (1:14.98) and spinosad @ 17.5 g a.i. ha⁻¹ (1:12.22). Studies on dissipation showed that, residues of triazophos persisted in cabbage up to 7th and 10th day with half-life of 2.66 and 2.87 days at recommended and double the recommended dose, respectively. Residues of quinalphos persisted in cabbage up to 5th and 7th day with half-life of 2.10 and 1.97 days at recommended and double the recommended dose, respectively. As regards bifenthrin residues persisted in cabbage up to 7th and 10th day with half-life of 2.30 and 2.52 days at recommended and double the recommended dose, respectively.

EFFECT OF DIFFERENT HOUSEHOLD PROCESSES ON PESTICIDES RESIDUES IN CABBAGE**C.G. SAWANT* AND C.S. PATIL***All India Network Project on Pesticide Residue, Department of Agricultural Entomology, Mahatma Phule Krishi Vidyapeeth, Rahuri-413 722, Maharashtra, India*

The investigations were carried out on 'Bio-efficacy of newer insecticides against diamondback moth (*Plutella xylostella* L.) and their residues in cabbage' during the year 2015-16 and 2016-2017 at M.P.K.V., Rahuri, Maharashtra. Field studies carried at Instructional Farm, P.G.I, M.P.K.V., Rahuri and laboratory studies were carried out at A.I.N.P. on Pesticide Residue, Department of Agril. Entomology, M.P.K.V., Rahuri. Among the various decontamination methods evaluated, cooking in close pan was found to be the most effective method in removing triazophos, quinalphos and bifenthrin residues from chopped cabbage samples (85.18, 85.42 and 86.27 %, respectively). Boiling was the next effective treatment which removed the triazophos, quinalphos and bifenthrin residues to the extent of 74.07, 81.25 and 80.39 per cent from chopped cabbage samples, respectively. Dipping of cabbage heads in 2 per cent salt solution reduced triazophos, quinalphos and bifenthrin residues to the extent of 51.85, 56.25 and 64.70 per cent, respectively. Reduction of residues due to dipping in 2 per cent tamarind solution was to the extent of 42.59, 41.67 and 56.86 per cent for triazophos, quinalphos and bifenthrin residues, respectively from cabbage heads. Washing of cabbage heads with tap water was observed to be the least effective in removing the residues of triazophos, quinalphos and bifenthrin residues (up to 25 %).

INVESTIGATION ON USAGE PATTERN, BIO-EFFICACY, DISSIPATION PATTERN AND DECONTAMINATION OF DIFFERENT INSECTICIDES AGAINST DIAMONDBACK MOTH (*PLUTELLA XYLOSTELLA* L.) IN CABBAGE**C.G. SAWANT* AND C.S. PATIL***All India Network Project on Pesticide Residue, Department of Agricultural Entomology, Mahatma Phule Krishi Vidyapeeth, Rahuri-413 722, Maharashtra, India*

The investigations were carried out on 'Bio-efficacy of newer insecticides against diamondback moth (*Plutella xylostella* L.) and their residues in cabbage' during the year 2015-16 and 2016-2017 at M.P.K.V., Rahuri, Maharashtra. Investigations comprised studies on pesticide use pattern, bio-efficacy of newer insecticides against *P. xylostella*, dissipation of triazophos, quinalphos and bifenthrin in cabbage and decontamination of residues in cabbage. Field studies were conducted at farmer's field (at Nandur Madhyameshwar, Tq. Niphad, Dist. Nashik and at Khandgaon, Tq. Sangamner, Dist. Ahmednagar), Instructional Farm, P.G.I, M.P.K.V., Rahuri and laboratory studies were carried out at A.I.N.P. on Pesticide Residue, Department of Agril. Entomology, M.P.K.V., Rahuri. Insecticide usage pattern of selected farmers from Ahmednagar, Pune and Nashik district of western Maharashtra indicated that, farmers relied mostly on chemical pesticides to control the insect pests of cabbage. Irrespective of location, farmers from these locations used conventional insecticides. Among three cabbage growing areas, the use of conventional insecticides was maximum by the farmers from Pune districts (1.43 kg a.i. ha⁻¹ season⁻¹) followed by Ahmednagar (1.22 kg a.i. ha⁻¹ season⁻¹) and Nashik districts (1.07 kg a.i. ha⁻¹ season⁻¹). As regards, use of novel insecticides, farmers from Nashik district used 0.38 kg a.i. ha⁻¹ season⁻¹ followed by Pune (0.24 kg a.i. ha⁻¹ season⁻¹) and Ahmednagar district (0.20 kg a.i. ha⁻¹ season⁻¹). Very few farmers from above locations used biopesticides i.e. Mycoinsecticides and neem based formulations. The most commonly used conventional insecticides were triazophos, quinalphos, dimethoate, dichlorvos, cypermethrin, profenophos and chlorpyrifos. About 50 per cent farmers were aware of natural enemies. Nearly 60 per cent farmers knew about the recommended insecticides and their doses on cabbage. Majority of the farmers indicated that they were aware of the residual effects of insecticides, but they did not follow any precautions to avoid harmful effects. It was also found that majority of the farmers did not know about safe waiting period for harvesting of cabbage after application of insecticides. Majority of the farmers sprayed at an interval of 7-10 days giving 5-7 rounds of spraying during cropping season of cabbage. Studies on bio-efficacy revealed that, chlorantraniliprole @ 10 g a.i. ha⁻¹ was found to be the most effective with 91.30 per cent reduction in larval population of *P. xylostella* followed by spinosad @ 17.5 g a.i. ha⁻¹ (87.55%) and flubendiamide @ 18.24 g a.i. ha⁻¹ (86.61%). The maximum marketable yield of cabbage heads (238.15 q ha⁻¹ with 129.23 % increase over control) was obtained from the plots treated with chlorantraniliprole @ 10 g a.i. ha⁻¹ followed by spinosad @ 17.5 g a.i. ha⁻¹ (233.83 q ha⁻¹ with 125.07 % increase over control) and flubendiamide @ 18.24 g a.i. ha⁻¹ (224.98 q ha⁻¹ with 116.56 % increase over control). The highest cost:benefit ratio was registered in the treatment of chlorantraniliprole @ 10 g a.i. ha⁻¹ (1:16.40) followed by flubendiamide @ 18.24 g a.i. ha⁻¹ (1:14.98) and spinosad @ 17.5 g a.i. ha⁻¹ (1:12.22). Studies on dissipation showed that, residues of triazophos persisted in cabbage up to 7th and 10th day with half-life of 2.66 and 2.87 days at recommended and double the recommended dose, respectively. Residues of quinalphos persisted in cabbage up to 5th and 7th day with half-life of 2.10 and 1.97 days at recommended and double the recommended dose, respectively. As regards bifenthrin residues persisted in cabbage up to 7th and 10th day with half-life of 2.30 and 2.52 days at recommended and double the recommended dose, respectively. Among the various decontamination methods evaluated, cooking in close pan was found to be the most effective method in removing triazophos, quinalphos and bifenthrin residues from chopped cabbage samples (85.18, 85.42 and 86.27 %, respectively).

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Boiling was the next effective treatment which removed the triazophos, quinalphos and bifenthrin residues to the extent of 74.07, 81.25 and 80.39 per cent from chopped cabbage samples, respectively. CREATING AWARENESS ON ORGANIC FARMING AMONG FARMERS FOR SUSTAINABLE AGRICULTURE**CHALLA SATISH REDDY¹ AND JHUNILATA BHUYAN²**

M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Home Science, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

According to the Food and Agriculture Organization (FAO), sustainable agriculture "is the successful management of resources for agriculture to satisfy changing human needs while maintaining or enhancing the quality of environment and conserving natural resources". Organic farming is one of the several approaches found to meet the objectives of sustainable agriculture. Many techniques used in organic farming like inter-cropping, mulching and integration of crops and livestock are not alien to various agriculture systems including the traditional agriculture practiced in old countries like India. The most important constraint felt in the progress of organic farming is the inability of the government policy making level to take a firm decision to promote organic agriculture. In addition, Organic Farming has vast opportunity for rural employment and livelihood security. Awareness of Organic Farming has a range of strengths in various areas including agriculture and food production, international relations, direct marketing and process auditing. Hence, there is a need for a comprehensive framework that integrates organic farming with bottom up responses, technology diffusion with reciprocal knowledge flow from farmers' institution and their local resources and innovation for sustainability in agriculture which will help generating large-scale farmers' acceptance to solve ecological crisis in context to climate change and to address the health and livelihood security of large rural masses of India.

Keywords: Organic Farming, soil and sustainable agriculture.

IMPRESSION OF WHEAT GENOTYPES UNDER NORMAL SOWN CONDITION ON YIELD AND ITS ASPECT**CHANDAN KUMAR UPADHYAY¹, SHASHANK SRIVASTAV¹, PAWAN KUMAR SINGH²**

Department of Crop Physiology¹, Department of Agronomy², Chandra Shekhar Azad University of Agril. & Tech. Kanpur-2

The study entitled "Impression of wheat genotypes under normal sown condition on yield and its aspect" was conducted at the Department of Crop Physiology, College of Agriculture Chandra Shekhar Azad University of Agriculture and Technology, Kanpur

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

during rabi season 2017. Twenty wheat varieties viz. K1006, K 8434, K 9423, K 8027, K 9351, K 607, K 307, K 9644, K 424, K 7903, K 9533, K9006, K 9465, K 906, K 402, K 9162, K 9107, K8962, PBW 343, HD 2733 were grown in field. Under control condition plots were irrigated at all growth stages. The condition plots were maintained under rain fed condition. Different physiological growth parameters were recorded at tillering, jointing, flowering and pod formation stages whereas yield and yield contributing parameters were recorded at maturity stage and after harvesting. The results showed that different physiological parameters such as relative growth rate (RGR), Net assimilation rate (NAR), and specific leaf weight (SLW). The wheat varieties K 9107, K 1006, K 9006 and PBW343 showed a good varieties maintained higher seed yield along with number of tillers per plant, seeds per ears test weight, seed yield, biological yield, harvest index and under normal condition. All these traits of the varieties helped them to maintain economic yield. The wheat varieties K 9107, and K 1006, K 9006 and PBW 343 varieties maintained higher seed yield along with number of leaves per plant, total dry matter, test weight, seed yield, biological yield, harvest index and yield under normal condition.

ECONOMICS OF HYBRID MAIZE PRODUCTION AS INFLUENCED BY DIFFERENT APPROACHES AND FORMS OF FERTILIZERS APPLICATION

CHANDRAKANT AND P. K. BASAVARAJA

Department of Soil Science and Agricultural Chemistry, College of Agriculture, University of Agricultural Sciences, GKVK, Bangalore - 560 065

A field experiment was conducted at Zonal Agricultural Research Station, University of Agricultural Sciences, GKVK, Bangalore to study the economics of hybrid maize as influenced by different forms of fertilizers through different approaches in eastern dry zone of Karnataka. The experiment was laid out in RCBD with ten treatments and replicated thrice. The results revealed that soil test crop response (STCR) dose through soluble fertilizer with 3 splits and 3 sprays recorded higher yield parameters like grain yield (98.22 q ha⁻¹) and stover yield (130.96 q ha⁻¹). Similarly, Higher gross returns were recorded (Rs.150279.54) in 100 per cent STCR dose applied through soluble fertilizers in three splits along with three sprays of 19:19:19 @ 1% concentration. Whereas, higher net returns were recorded (Rs.104447.97) in 100 per cent RDF applied plot through conventional fertilizers. However, higher Benefit:Cost (B:C) ratio was observed in recommended dose of fertilizer (RDF) through conventional fertilizer (4.20) followed by STCR dose through conventional fertilizers (3.62) and lower B:C ratio recorded in treatment receiving soluble fertilizers irrespective of the forms and approaches of fertilizer application was mainly due to higher cost for soluble fertilizers compared to conventional fertilizers which were subsidized under government policy.

BIOFORTIFICATION; A MAJOR CHALLENGE IN HORTICULTURE INDUSTRY IN INDIA

CHANDRASHEKAR K. G. ^{*1}, PARASHURAM M. ² AND VIKASA. A. N. ³

Department of Fruit Science, ² Department of Floriculture and Landscaping, College of Horticulture, Bagalkot, University of Horticultural Sciences, Bagalkot-587 104. Department of Horticulture, University of Agricultural Sciences, GKVK, Bengaluru-560 065

Biofortification is the process of breeding for improved nutrient content in a crop and is considered a sustainable and cost effective strategy to address malnutrition to rural peoples in developing countries because it targets staple foods that are consumed daily. *About 800 million people suffer from hunger, but even more suffer from micronutrient malnutrition particularly iodine, vitamin A, iron, and zinc malnutrition are major concerns. Presently, agronomic, conventional and transgenic are three common approaches are in limited scale in use. Agronomic Practices used to enhance concentration of phytonutrients. Stresses such as water stress, cold and ultraviolet light can significantly enhance production of phytonutrients such as flavonoids and glucosinolates. In conventional plant breeding, parent lines with high vitamin or mineral levels can be crossed over several generations to produce plants that have the desired nutrients. Recent progress in conventional plant breeding has given emphasis on fortification of important vitamins, antioxidants and micronutrients. Transgenic approaches are advantageous when the nutrient does not naturally exist in a crop (example, provitamin A in sweet potato and cassava). Recently, there have been more focusing on development of transgenic crops to enhance levels pro-vitamin A content in several horticultural crops like tomato, potato, banana, cassava, sweet potato, carrot etc. Biofortification provides a feasible means of reaching malnourished populations in relatively remote rural areas, delivering naturally fortified foods to people with limited access to commercially-marketed fortified foods, which are more readily available in urban areas. Thus, the best and final solution to eliminating under nutrition as a public health problem in developing countries is to provide increased consumption of a range of non-staple foods. Plant breeders need to be aware of both the major influence that horticulture research may have had on nutrient utilisation in the past and the potential of plant breeding for future improvements in nutrition and health.*

Key words: Biofortification, Approaches, Horticultural crops.

EFFICACY OF EDIBLE COATING AND CHEMICALS ON THE SHELF LIFE QUALITY OF FRUITS AND VEGETABLES

Chandrashekar K. G. ^{*1}, Parashuram M. ² and Vikasa. A. N. ³, *Department of Fruit Science, ² Department of Floriculture and Landscaping, College of Horticulture, Bagalkot, University of Horticultural Sciences, Bagalkot-587 104. Department of Horticulture, University of Agricultural Sciences, GKVK, Bangalore-560 065*

Post harvest losses of fruits and vegetables are serious problem because of rapid deterioration during handling, transport and storage in tropical regions. The Indian fruits and vegetable market is one of the largest in the world. It has certain unique characteristics viz., high wastage in value chain, weak transportation and storage infrastructure, low tech harvestings, low usage in food processing and relatively low exports. The post-harvest losses between 35 and 40% and valued at about \$800 million annually, affect the livelihoods of nearly one-third of the population, the majority of whom are smallholder farmers. In order to limit the post-harvest changes in a commodity, an environmental friendly technology i.e. edible coating can be applied. In this, a commodity is enrobed using natural polymers. This technology offers various advantages like maintaining food quality and increasing shelf life by delaying the ripening process, colour changes, maintaining texture, reducing weight loss and decay. This coating can be done in various ways like dipping the product into, or by spraying it or brushing with a solution containing film ingredients. Edible coatings are usually made from materials such as polysaccharides, proteins and lipids. Edible coatings have high potential to control browning, discolour activity, off flavour, microbial activity of fruits and vegetables and to extend shelf life. Several new formulations have been developed which serve as a best alternative. These are made from herbs or combination of other edible coatings and the most common herbs used in edible coatings are such as *Aloe vera* gel, neem, lemon grass, rosemary, oregano and turmeric etc. Therefore, prospects of studies pertaining to improve coating adhesion and durability on the surface of fruits and vegetables and investigations on sensory quality and consumer acceptance of coated products are needed.

Key words: Post harvest loss, edible coating, vegetable and fruit crops

YIELD AND ECONOMIC OF SUMMER PEARL MILLET AS INFLUENCED BY INTEGRATED NITROGEN MANAGEMENT

CHAUDHARI, N. N., PATEL, D. D. AND VIRDIA, H. M.

Department of Agronomy, Navsari Agricultural University, Navsari-386 450 (Gujarat), India

A field experiment was conducted during summer, 2015 at Agronomy Instructional Farm, N. M. College of Agriculture, Navsari Agricultural University, Navsari, to study the "Integrated nitrogen management in summer pearl millet under South Gujarat condition". Total nine integrated nitrogen treatments of chemical fertilizers with organic manures with three replications in randomized block design. The results revealed that pearl millet GHB-558 performed better by combined application of 50% RDN from chemical fertilizers + 25% nitrogen from vermicompost + 25% nitrogen from neemcake recorded higher value for plant height, dry matter accumulation per plant, total tillers per plant, earhead length, earhead girth, effective tillers, test weight, grain yield per earhead as well as grain (2057 kg/ha) and straw yield (5347 kg/ha) over other combinations. Maximum net realization (18773 Rs./ha) along with higher BCR value (0.71) were recorded with 50% RDN from chemical + 25% nitrogen from vermicompost + 25% nitrogen from neemcake.

RESPONSE OF INTEGRATED NUTRIENT MANAGEMENT ON THE PERFORMANCE OF FENUGREEK (*TRIGONELLA FOENUM-GRACUML.*) IN CLAY LOAMY SOIL

C.K. DOTANIYA¹, R.K. NIRANJAN², H.C. DIXIT² SANDEEP MOHBE¹, R.K. DOUTANIYA³

¹Dept. of Soil Science and Agricultural Chemistry, ICAR-Indian Institute of Soil Science Bhopal M.P. 462038, ² Nehru P.G. collage Lalitpur, Bundelkhand University Jhansi U.P., ³Department of Agronomy O.P.J.S. University Churu Rajasthan

A Pot experiment was conducted to study Response of Integrated Nutrient Management on the performance of Fenugreek at Agriculture experimental field, Bundelkhand University Jhansi (U.P.) during 2014-15. The experimental design use RBD with consisting four levels of such vermicompost - (0, 100, 200, 300 gm) FYM - (0, 100, 200, 300 gm) and rhizobium - (0, 10, 20, 30 kg/ha) respectively. The results reflected that application of integrated nutrient management increased the seed yield (kg/ha) as compared to control. Seed yield obtained at different levels of vermicompost 14.25, 14.27 and 14.33 followed by Farm Yard Manure 14.27, 14.25 and 14.27 and rhizobium 13.07, 13.08 and 13.12 q/ha.

Key words- Integrated Nutrient Management, Vermicompost, FYM, Rhizobium, Fenugreek

COMBINING ABILITY ANALYSIS OF INTRA HIRSUTUM CROSSES FOR SEED COTTON YIELD AND ITS ATTRIBUTES IN COTTON**CHHAVIKANT¹, K.S. NIRANIA¹, S.R. PUNDIR¹**¹*Department of Genetics & Plant Breeding, CCS Haryana Agricultural University, Hisar-125004*

Present investigation was carried out to evaluate forty intra hirsutum hybrids, produced through crossing of 5 hirsutum lines (H1300, H1098i, H1117, H1226 and H1236) with 8 hirsutum testers (GN 67-1, HS-2, LH 1960, P 729-37, RS 875, Mahalaxmi, RST-9 and PIL-18) by Line x Tester method for general combining ability of the parents and specific combining ability of hybrids in respect of seed cotton yield, its attributing traits viz., boll number, boll weight, morphological traits viz., plant height, number of monopods, number of sympods and for important economic parameters viz., ginning out turn, seed index and lint index. The 40 F₁ intra hirsutum hybrids were sown during Kharif 2015-16 in a randomized block design with three replications at CCS Haryana Agricultural University, Cotton Research Station Sirsa. From the estimates of additive and dominance variance, it was observed that SCA variance was greater than GCA variance for all the characters except boll weight, ginning out turn and lint index, indicating the involvement of both additive and non-additive gene effects with the preponderance of non-additive gene effect for genetic control of these characters. Among all the studied hybrids, cross combinations H1226 x RS 875, H1300 x P 729-37, H1300 x PIL-18, H1300 x HS-2 and H1098i x Mahalaxmi were found to be best specific combiners, while best general combiner were male parents LH 1960 & P 729-37 and female parent H1098i.

Keywords: Combining ability, hirsutum, Line x tester analysis.

FERNS DIVERSITY IN SWAMPY HABITAT OF DOON VALLEY**CHHAYASINGH*, NEHA CHAUHAN*, SHAGUN GUPTA****SGRRU, Dehradun*

Wetlands are special type of habitat which have received great attention for their conservation and management by UNESCO, IUCN, IBP etc. Kanjilal (1901) focused attention towards the great botanical potential of the swamp forest in Doon valley. He described Mothronwala, Nakraunda, and Golatapar swamp forest in his work for their great botanical interest. Ferns are found in varied habitat but sometimes they are found in unusual habitat. The ravine and gorges are popularly known as "fern centers". The vegetation and botanical value of swamps were first observed by Kanjilal (1901). The Mothronwala swamp of study area is a well known as "Hot Spot" of biodiversity due to topographic and edaphic variations. The fern species of such areas include *Ampelopteris prolifera* (Retz.) Copel., *Christella arida* (D. Don) Holtt., *Christella dentate* (Forssk.) Brown., *Coniogramma fraxinea* (D. Don) Fee ex Diels (*moist habitats*), *Woodwardia ungiemmata* C. Presl. (Shady ravines along water side). Increase in Anthropogenic activities such as cutting of trees, overgrazing of swamp by the local people, there is decline in swamp species. It requires urgent conservation and protection of the area. The present paper focuses on various conservation measures to protect biodiversity of ferns of these swamps.

MULCHING: EFFECTIVE PRACTICE FOR REDUCING SOIL WATER EROSION**CHOLLANGI PRASANTH KUMAR¹ AND DEEPAK KUMAR MOHANTY²***M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Senior Scientist and Head, Dept. of Ag. Engineering, Krishi Vigyan Kendra Mayurbhanj-II, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha*

Mulching is referred to as the soil water conservation practice of leaving mulch on the soil surface for soil and water conservation and to favour plant growth. In these contexts, soil erosion by water is a serious problem, especially in semi-arid and semi-humid areas of the world. The term 'mulch' refers to any material other than soil or living vegetation that performs the function of a permanent or semi-permanent protective cover over the soil surface. Different materials can be used, such as vegetative residues, biological geo textiles, gravel and crushed stones. Mulching has been shown several beneficial effects. It protects the soil against raindrop impact, thereby reducing the water and soil loss rates in different environments, such as agricultural lands, rangelands, fire affected and anthropic sites. It also reduces both the overland flow generation rates and velocity by increasing roughness and it cuts the sediment and nutrient concentrations in runoff. Mulching has been shown to confer several beneficial effects. Furthermore, mulching allows improved infiltration capacity and increases water intake and storage. It enhances the activity of some species of earthworms as well as crop performance, interactions with, the soil structure and the organic matter content with in soil. Hence, Mulching act effectively in reduce soil and water losses in different environments.

Keywords: Mulching, soil and water.

A COMPREHENSIVE STUDY ON KARNAL BUNT DISEASE OF WHEAT IN EASTERN UTTAR PRADESH**D.N.SHUKLA,* J.P.SRIVASTAVA AND AMIT MAURYA***Department of Plant Pathology, Narendra Deva University of Agriculture & Technology Kumarganj Faizabad (UP)*

Karnal bunt caused by *Tilletia indica* Mitra (*Neovossia indica* Mitra (Mundkur) was first recorded in April, 1930 from Botanical Research Station, Karnal (Haryana) on wheat cultivar, foundation and Punjab A. The disease was prevalent in the sub-continent since long, infecting native wheats grown over North Western India but it never caused serious yield reduction. In the absence of strict domestic quarantine regulation, it spreaded to new areas in North Western Wheat belt. However, Madhya Pradesh, southern Rajasthan, Maharashtra and Peninsular India are free from Karnal bunt due to high temperatures. Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad has a well-equipped notified Seed Testing Laboratory under the Department of Seed Science & Technology. Samples of different release and notified varieties meant for quality seed production purposes i.e. nucleus, breeder, foundation and certified seed at different seed production farms/KVK of the University established at different location in Eastern Uttar Pradesh are collected and analysed for testing against seed quality traits like germination, physical purity, genetic purity, seed vigour, seed health etc. Total 26 seeds samples comprising 11 released and notified varieties under university seed production chain were available in the seed testing lab from the produce of Rabi 2011-12. A part from the said seed samples were obtained and analysed for Karnal bunt of wheat. Maximum average infection percentage was found in variety of PBW-343(0.15%) of Faizabad Produced and minimum average was found in the variety of UP-262(0.10%), the varieties were DBW-17, K-307, NW-1012 and K-9423 found free from Karnal bunt. Studies indicated that varieties like Raj-3077, HD-2733, NW-1012, K-307, K-9423 and DBW-17 are safer against the disease. Due to very low disease incidence the results regarding the suitability of sowing date and fertilizer levels found inconclusive and fungicides namely carboxin (Vitavax 75WP), Carbendazim (Bavistin 50WP), Subeej (Bavistin 25SD), Propiconazole (Tilt 20EC), Vitavax power (Crompton. Uni. Royal) along with one untreated control. All these five fungicides were tested at three concentrations i.e. 0.1%, 1.0% and 2.5%. The radial growth was measured after 15 days and per cent inhibition radial growth was calculated and propiconazole (Tilt 20EC) was found most inhibitory against the radial growth.

CHARACTERIZATION AND CLASSIFICATION OF ELITE GENOTYPES OF CHICKPEA (*CICER ARIETINUM* L.) FOR MORPHOLOGICAL CHARACTERS USING DUS DESCRIPTORS**D.K. JANGHEL*, KRISHAN KUMAR, S.S. VERMA AND A.K. CHHABRA***Department of Genetics and Plant Breeding, College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, (125 004), India.*

In this present investigation, the 60 chickpea genotypes were characterized and grouped into different classes as per the guidelines for the conduct of test for Distinctiveness, Uniformity and Stability (DUS) on chickpea (*Cicer arietinum* L.) approved by the Protection of Plant Varieties and Farmers' Rights Authority (PPV&FRA) in 2007, Government of India. Among the 13 morphological characters observed, seven characters were found trimorphic viz., plant growth habit, leaflet size, flower colour, peduncle length, pod size, seed shape and seed testa texture, four characters dimorphic viz., anthocyanin pigmentation on stem, number of flowers per peduncle, stripes on flower and seed type, and two characters polymorphic viz., foliage colour and seed colour among all the 60 chickpea genotypes indicating great potential for varietal identification and characterization. A substantial level of genetic diversity was also observed based on morphological descriptors for all the chickpea genotypes. From the above 13 morphological DUS descriptors a unique morphological profiles could be established for the each chickpea genotype. Thus two important conclusions emerged out from the present investigation, (i) there exists remarkable variability among the present chickpea genotypes and (ii) 13 DUS parameters were adequate to assign a distinctive profile (combination of traits) to each chickpea genotype qualifying them to be fit for registration as a diverse genotype. Moreover, diverse but complementary genotypes may be selected for inclusion in the breeding programmes to develop elite breeding material for the development of improved chickpea varieties.

Keywords: Chickpea, DUS, PPV&FRA, unique profile and Genetic diversity.

EFFECT OF PHOSPHORUS AND ZINC ON YIELD AND QUALITY OF GROUNDNUT (*ARACHIS HYPOGAEA* L.) IN INCEPTISOL.**D. V. KADAM, B.S. INDULKAR, V. S. KADAM, L. S. JADHAV, P. N. SONUNE***Department of Soil Science and Agriculture Chemistry, College of Agriculture, Latur Vasantrao Naik Marathawada Krishi Vidyapeeth, Parbhani 431402, (M.S.), India.*

The experiment was laid out in FRBD with 16 treatments along with 3 replication. It was carried out during the Kharif season 2018, at farm of oilseed research station, College of Agriculture, Latur. The results of field trial on response of various levels of Phosphorus and zinc showed significant effect on yield and quality parameter of groundnut. The pod, kernel and haulm yield was significantly affected at

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

P_2 - 50 kg P_2O_5 ha⁻¹ and zinc level at Zn_2 -30 kg $ZnSO_4$ ha⁻¹ as compare to all other levels of phosphorus and zinc. The quality parameter like oil content, protein content and oil and protein yield showed maximum increases due to application of phosphorus at P_2 - 50 kg P_2O_5 ha⁻¹ and zinc Zn_2 -30 kg $ZnSO_4$ ha⁻¹ in kernel of groundnut. Thus, it can be concluded that balanced fertilizer application of phosphorus at level of P_2 - 50 kg P_2O_5 ha⁻¹ and zinc Zn_2 -30 kg $ZnSO_4$ ha⁻¹ showed superiority over all other levels of P and Zn. However, further increment of P, P_3 -60 kg P_2O_5 ha⁻¹ and Zn, Zn_3 - 40 kg $ZnSO_4$ ha⁻¹ was found be better when compared with P_1 (40 kg P_2O_5 ha⁻¹) and Zn_1 (20 kg $ZnSO_4$ ha⁻¹). Thus application of P_2 (50 kg P_2O_5 ha⁻¹) along with zinc level at Zn_2 (30 kg $ZnSO_4$ ha⁻¹) was found to be beneficial in increasing yield and quality of groundnut on low phosphorus and zinc containing ineceptisol soil.

PUSH AND PULL STRATEGY FOR CONTROL OF MAIZE STEMBORERS**D. VAMSI CHANDRASEKHAR REDDY, ABHISHEK YADAV AND M. SREEDHAR***Department of Entomology, SVPUA&T, Meerut-250 110*

The lepidopteran stemborers cause major yield losses in maize production. A habitat management strategy for minimizing damage due to stemborers has been developed in maize-based farming systems was push and pull strategy. For stemborers, this strategy involves use of trap crops to attract stemborer colonization away from the maize plants (pull) and intercrops to repel the pests (push). The two most successful trap crop plants Napier grass, *Pennisetum purpureum*, and Sudan grass, *Sorghum vulgare sudanensis*, attracted greater oviposition by stemborers, than cultivated maize. The intercrops giving maximum repellent effect were molasses grass, *Melinis minutiflora* and a legume species, silverleaf, *Desmodium uncinatum*. These trap crops produces volatile chemicals, such as octanal, nonanal, naphthalene, 4-allylanisole, eugenol and linalool, attract female moths (pull) to lay eggs. While those volatile chemicals released by intercrops, such as (E)- β -ocimene and (E)-4,8-dimethyl-1,3,7-nonatriene, which repel the stemborer moths from the maize (push). The volatile chemicals emitted by inter crops not only repelled female stemborer moths but also attracted parasitoids, principally foraging female *Cotesia sesamiae*. Push-pull is one of the most successful examples of conservation biological control, which holds great promise for maize growing regions. In addition to enhancing maize yields, the strategy increased small livestock production, conserved soil resources, controlled important weeds, enhanced functional biodiversity and increased incomes. Push-pull is an appropriate technology for poor farmers because it is based on locally available renewable inputs and can thus be easily integrated into traditional poly-culture cropping systems. On a larger scale, principles of push-pull can be applied to low-inputs and organic agriculture systems worldwide.

CHARACTERIZATION AND CLASSIFICATION OF ELITE GENOTYPES OF CHICKPEA (*CICER ARIETINUM* L.) FOR MORPHOLOGICAL CHARACTERS USING DUS DESCRIPTORS**D.K. JANGHEL*, KRISHAN KUMAR, S.S. VERMA AND A.K. CHHABRA***Department of Genetics and Plant Breeding, College of Agriculture, Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, (125 004), India.*

In this present investigation, the 60 chickpea genotypes were characterized and grouped into different classes as per the guidelines for the conduct of test for Distinctiveness, Uniformity and Stability (DUS) on chickpea (*Cicer arietinum* L.) approved by the Protection of Plant Varieties and Farmers' Rights Authority (PPV&FRA) in 2007, Government of India. Among the 13 morphological characters observed, seven characters were found trimorphic viz., plant growth habit, leaflet size, flower colour, peduncle length, pod size, seed shape and seed testa texture, four characters dimorphic viz., anthocyanin pigmentation on stem, number of flowers per peduncle, stripes on flower and seed type, and two characters polymorphic viz., foliage colour and seed colour among all the 60 chickpea genotypes indicating great potential for varietal identification and characterization. IMPACT OF DEMONSTRATIONS ON YIELD AND ECONOMICS OF MAJOR VEGETABLE CROPS**DAN SINGH¹, R.N.YADAV², D.K.SINGH³ AND H.L.SINGH³***Department of Agricultural Extension and Communication, S.V.P.U.A.&T., Meerut, Professor, Department of Agricultural Extension and Communication, S.V.P.U.A.&T., Meerut, Professor, Department of Agricultural Economics and Management, S.V.P.U.A. & T., Meerut*

The present study was conducted in four blocks of Hapur and Saharanpur district of Western Uttar Pradesh. The total sample size was of 160 vegetable growers for the investigation. During the research study it was observed that increase the yield of vegetable crops from 16.66 to 22.45 percent under demonstrations in compare to farmers practice in summer and kharif season (2014-15). The highest cost of cultivation was found in tomato crop i.e. Rs.2,50,000/ha., lowest in sponge gourd i.e. Rs.77,413/ha., highest net return received in tomato crop i.e. Rs. 1,75,000/ha., lowest in bitter gourd crop i.e. Rs. 17,379/ha. and benefit cost ration was higher in chilli crop i.e. 1:1.82 and lowest in bitter gourd crop i.e. 1:1.16. In Rabi season 2015-16 increase yield of demonstrations from 25.39 to 33.92 percent over the farmers practice. The highest cost of cultivation was found in tomato crop i.e. Rs.2,43,000/ha., lowest in bottle gourd i.e. Rs. 1,01,000/ha., highest net return received in cabbage crop i.e. Rs. 1,33,695/ha., lowest in chilli crop i.e. Rs. 47,200/ha. and benefit cost ration was higher in brinjal crop i.e. 1:1.77 and lowest in tomato crop i.e. 1:1.42. Increase yield of demonstrations from 25.00 to 36.90 percent over the farmers practice. The highest cost of cultivation was found in okra crop i.e. Rs.2,17,312/ha., lowest in sponge gourd i.e. Rs.80,000/ha., highest net return received in brinjal crop i.e. Rs. 1,95,000/ha., lowest in bitter gourd crop i.e. Rs. 55,625/ha. and benefit cost ratio was higher in cucumber i.e. 1:1.97 and lowest in bitter gourd i.e. 1:1.30 in summer and kharif season 2015-16. The highest yield gap was found in brinjal and cabbage.

CLIMATE SMART AGRICULTURE: NEED OF HOUR**DANISHTAAZIZ***Department/Subject- Entomology, SKUAST-KASHMIR, FAO, WADURA*

Multiple climate changes have occurred over the past several decades across the world, including increasing temperatures, changes in water availability and precipitation, and increasing instances of floods. These changing climatic conditions, especially over the last twenty years, have presented multiple risks to the country's agricultural sector, affecting the productivity and quality of crops. Marked changes in rainfall dynamics, with more frequent and intense precipitation events, and more frequent and pronounced drought events that disrupt farming and other economic activities, have presented new challenges for farmers. Farmers are now forced to respond to these adverse changes that affect the way they are familiar to farming and threaten to destabilize the economic viability of many farming communities. These changes, along with increasing climate variability, have influenced soil fertility, crop selection, and harvesting times. The emerging challenges have prompted a need for change in agricultural practices and technologies on the islands. Innovators in the community of farmers in world have realized that to tackle these issues, both mitigation and adaptation measures need to be implemented, and have thus committed to working towards creating more resilient agricultural systems.

Key Words: Climate, Smart, Agriculture, Floods, rainfall, soil fertility

ROLE OF IPM IN SUSTAINABLE AGRICULTURE**DAVARKARAM***Entomology and Agricultural Zoology Institute of Ag. sciences BHU VARANASI)*

IPM is a holistic approach (cultural, physical, biological, chemical & genetic methods) to sustainable agriculture that focuses on managing insects, weeds & diseases. They are cost effective, environment friendly & socially acceptable. This includes the responsible use of crop protection & plant biotech products. The IPM strategies use in sustainable agriculture save the environment and save the soil fertility. IPM also important in increasing crop production. Resistance method is a important key in sustainable agriculture. In resistance method include resistance varieties use against to insects, pests and diseases that can helps farmer in managing the crops. IPM also use in improve soil and water quality, reduced farmer and consumers risks from pesticides poisoning and related hazards. It also manages ecological sustainability by conserving natural enemy species, biodiversity and genetic diversity. It also promotes sound structures and healthy plants. IPM reduces the environmental risk associated with pest management by encouraging the adoption of more ecologically begin control tactics. Biological control can be effective in all types of agriculture systems, including organic, sustainable, and conventional. But certain biological control approaches certainly have the potential to conform to the sustainable agriculture philosophy. In IPM biological control includes parasitoids, predators, natural enemies etc. are effective roll in sustainable agriculture. Also, biological control is often location and management system specific, so requires intense knowledge of relatively unique conditions that may not be applicable on a wide scale basis, again a problem for marketing product.

KEYWORDS: IPM, PESTICIDES, BIOLOGICAL CONTROL, SUSTAINABLE AGRICULTURE, ENVIRONMENT.

PLANT GROWTH AND NUTRIENT UPTAKE BY WHEAT GROWN IN A TYPIC USTOCHREP OF WESTERN U.P. AS AFFECTED BY FERTILIZER-N AND SCHEDULING OF IRRIGATION.

DEVENDRAPAL, TULSARAM AND VIPIN KUMAR*

Krishi Vigyan Kendra, Muradnagar, Ghaziabad & Krishi Vigyan Kendra, G.B.Nagar, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut.*

An investigation on plant growth and nutrient uptake by wheat grown in a Typical Ustochrep of Western U.P. as affected by fertilizer-N and scheduling of irrigation was conducted during Rabi season of 1st, 2nd and 3rd year in randomized block design at Crop Research Centre, Modipuram, Meerut. The experiment comprising three replications of 20 treatment combinations of four irrigation levels (2, 3, 4 & 5) and five nitrogen levels (0, 60, 90, 120 and 150 Kg. ha⁻¹). The results showed that higher irrigation decreased available nitrogen in soil whereas no effect was observed on available P, K and Zn. However, it increased plant height, number of effective tillers m⁻¹, grain and straw yield. It also had a positive relationship with uptake of N, P, K and Zn, nitrogen use efficiency, apparent nitrogen recovery and physiological efficiency. Nitrogen application upto 150 N Kg ha⁻¹ caused an increase in plant height, effective tillers m⁻¹, grain and straw yield, nutrient (N, P, K and Zn) uptake it caused a decrease in nitrogen use efficiency, apparent nitrogen recovery and physiological efficiency of wheat.

EFFECT OF RATES OF FENOXAPROP-P-ETHYL ALONE AND IN COMBINATION WITH ISOPROTURON ON WHEAT AND ASSOCIATED WEEDS

DEVENDRAPAL* AND SATYA PRAKASH*

**Krishi Vigyan Kendra, Muradnagar Ghaziabad (U.P.), Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut*

An experiment was conducted during Rabi season of two year data from crop research center at Pantnagar to assess the appropriate rate of fenoxaprop-p-ethyl alone and in combination with isoproturon with respect to weed control efficiency, crop growth, yield attributing character, yield and nutrient uptake by crop and weeds in wheat crop. Out of four treatments of fenoxaprop-p-ethyl (40, 60, 80 and 90 g a.i. ha⁻¹) and three in combination with isoproturon (30+500, 40+500 and 50+500 g a.i. ha⁻¹) the maximum wheat control efficiency, crop growth, yield attributing character, yield and NPK uptake by plants and lower dry matter of weeds and NPK uptake by weeds were found in fenoxaprop-p-ethyl at 90 g a.i. ha⁻¹ alone and in tank mixture of fenoxaprop-p-ethyl and isoproturon at 50+500 g a.i. ha⁻¹ during both the years. Results revealed that higher rates of fenoxaprop-p-ethyl alone or in combination with isoproturon were more effective in reducing density and dry matter of *P. minor* and *A. ludoviciana* as well as total weeds. It may be due to excellent weed control efficiency at this of herbicides. The highest yield (5056 kg ha⁻¹) was recorded under weed-free condition. Fenoxaprop-p-ethyl at 90 g a.i. ha⁻¹ and a tank mixture of fenoxaprop-p-ethyl and isoproturon at 50+500 g a.i. ha⁻¹ produced grain yield at par with weed-free condition during both the years. This may be due to increase in crop dry matter, leaf area index, number of spike (m⁻²), length of spike, number of grains spike⁻¹ and 1000-grain weight. There was increase in the uptake of N, P and K ha⁻¹ by crop at 60 days stage and at harvest by increasing rate of fenoxaprop-p-ethyl either alone or tank mixture with isoproturon at 500 g a.i. ha⁻¹. This may be due to higher level of weed control and lower level of nutrients shaved by weeds.

"TO STUDIES OF EVALUATION OF SINGLE ROW MAIZE PLANTER"

DEVESH KUMAR

ICAR-Indian Agricultural Research Institute, New Delhi India

Maize cultivation gets popularity now days in our country because use of maize in human food and especially in the poultry industries. Maize is cultivated manually which is time consuming, labor intensive and costly. A low cost manually operated push type maize planter was designed and the planter consists of two supportive wheels behind the planter, a seed hopper, a vertical plate type seed metering device, a seed tube, a pair of bed former and handle. Power was transmitted from the ground wheels to the metering device through gear. Maize Seeds were used to test the planter. The seed planter was calibrated in the workshop of the department of Farm Machinery and Power Engineers to maintain the desired seed rate and seed rate was calculated as 20 kg/ha. In the field test the effective field capacity, field efficiency, and draft were calculated in three forward speed levels at 1 km/h, 1.5 km/h and 2 km/h as 2 ha/h, 62.51%, 35 kgf; 3.05 ha/h, 67.91%, 25.60 kgf and 4.5 hec/h, 75.49%, 17.5 kgf for area 100 m². The best performance of the maize planter was found at a 2 km/h as a highest effective capacity, field efficiency and lower draft among them. Production of maize in India 147.10 lakh ton and in Uttar Pradesh 10.50 lakh ton as at 2005 -2006 data source from official website of government of India and Uttar Pradesh, jowar Bajra and maize occupies an area of 34830 hectare and in Allahabad district the productivity is 0.92 quintal per hectare. The maize is grown

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

throughout the year in all states of the country for various purposes including fodder for animals,

Keywords: Maize cultivation, seed hopper, metering device, field efficiency, field capacity, speed

ROLE OF AGRO-METEOROLOGICAL ADVISORY SERVICES ON RISK MITIGATION IN AGRICULTURE

DAYANIDHI CHAUBEY¹*, VED PRAKASH¹, ARVIND BHAI PATEL¹ AND TIKAM CHAND YADAV²

¹Department of Agronomy, Bihar Agricultural University, Sabour (Bhagalpur)- 813 210, Bihar, India, ²Department of Soil Science and Agricultural Chemistry, Jawaharlal Nehru Krishi Vishwa Vidyalaya (JNKVV), Jabalpur- 482 004 (M.P), India

One of the major challenges faced by human kind is to provide. In present decades, anomalous weather and climate have drastically impact on agricultural production and increase risk in India. It also impact the quality, if not the absolute production levels, of a crop. Agro-meteorological Advisory Services (AAS) communicated to the farmers on every day, daily weather data and weather forecasting are given to the newspapers on phone call. Agro advisory bulletin (bi-weekly) is prepared and sent to all government bodies, NGO's, Kisan helpline, ETV, All India radio etc. through E-mail and is uploaded on the website working on office day and time. The rising weather risks affect the livelihoods of farmers and GDP growth of the country. Under increasing threat condition, it is becoming increasingly important for farmers to proactively manage the weather and climate risks to agriculture to protect their livelihoods.

Key word: AAS, Agro advisory bulletin, Climate change, Livelihood, Weather forecast

RESPONSE OF SPRING SWEET CORN TO MOISTURE CONSERVATION PRACTICES

DEBARATI DATTA¹*, SUBHASH CHANDRA², SUKANYA GHOSH³ AND SOURAV GHOSH⁴

¹PhD Scholar, Department of Agronomy, GBPUA&T, Pantnagar, Uttarakhand, ²Chief Scientist, Department of Agronomy, GBPUA&T, Pantnagar, Uttarakhand, ³PhD Scholar, Department of Soil Science, GBPUA&T, Pantnagar, Uttarakhand, ⁴PhD Scholar, Department of Agronomy, IARI, New Delhi

An experiment was conducted during spring season of 2017 and 2018 at Govind Ballabh Pant University of Agriculture and Technology, Pantnagar to investigate the effect of irrigation scheduling, method of establishment and moisture conservation practices in spring season sweet corn. Popularity of sweet corn is increasing amongst the farmers due to short duration and high economic returns. Sweet corn crop besides providing green cobs also produce good quality fodder for milch animals. High ET owing to high temperature during spring season enforces high irrigation frequency which leads to high cost of cultivation. Irrigation was applied at three ratios (IW: CPE of 1.0, 1.2 and 1.4). Sowing was done in flat plots and furrows and moisture conservation practices like biochar @ 3.0 t/ha and mulch @ 6.0 t/ha was adopted. Sweet corn responded significantly upto IW: CPE ratio 1.2 requiring total 8 irrigations. IW: CPE 1.2 and 1.4 were found to be statistically at par with each other but superior to 1.0. Furrow sowing saved 25% irrigation water. Among the moisture conservation practices, biochar and mulch recorded superior value in terms of yield (5.2 % and 5.8 %, respectively) and irrigation water use efficiency than control. Biochar and mulch treatments did not differ significantly for green cob yield.

TECHNOLOGICAL ADVANCEMENT IN PLANT DISEASE DIAGNOSIS

DECHAN CHOSKIT, KAUSAR FATIMA, TSERING DOLKAR¹, AQLEEMA BANOO² AND J P RATHORE¹

Division of Plant Pathology, SKUAST-Jammu, ¹Division of Fruit Science, ²Division of Plant Pathology, SKUAST-Kashmir, Srinagar

Plant diseases cause substantial losses in yield of plants, leading to huge economic losses. Accurate identification and diagnosis of plant diseases are very important in the era of climate change and globalization for food security as well as prevention of the spread of invasive pests/pathogens. In addition, for an efficient and economical management of plant diseases accurate, sensitive and specific diagnosis is necessary. Further, traditional methods of scoring disease severity are not reliable for estimating disease in the population due to lack of uniformity and requirement of expertise in the procedure. The science of plant disease diagnosis has evolved from visual inspection and identification of plant diseases to detect with high-throughput serological techniques like enzyme-linked immunosorbent assay (ELISA) and molecular methods such as polymerase chain reaction (PCR) and their variants. Diagnosis technique like the lateral flow-ELISA is applicable at the field or at any part of the production and distribution system; for instance, is widely utilised for *Phytophthora infestans*, *Ralstonia solanacearum*, tomato mosaic virus and many other pathogens. With the applications of bioinformatics in plant pathology, identification of specific motifs, DNA sequences has become possible, which ultimately increase the accuracy of modern techniques in plant disease diagnosis. Though advances have been made in every aspect of diagnosis of plant diseases; increasing sensitivity and specificity have remained the key area for development.

JATROPHA BIODIESEL : FUTURE SUSTAINABLE FUEL**DEEKSHANAROLIA***Institute Of Agricultural Science, Bundelkhand, University, Jhansi*

Jatropha oil is produced from the seeds of the *jatroha curcas*, a plant that can grow in wastelands across India, and the oil is considered to be an excellent source of bio diesel Jatropha cultivation and will provide much needed employment to the rural poor of India . Businesses are also seeing the planting of Jatropha as a good business opportunity. Increased Jatropha oil production delivers economic benefits to India on the macroeconomic or national level as it reduces the nation's fossil fuel import bill for diesel production ,minimising the expenditure of India's foreigncurrency reserves for fuel allowing India to increase its growing foreign currency reserves .The study has revealed that jatropha plantation in India is economically viable Since the cost needed for plantation is relatively lower The plantation activities would become attractive for the grower .The plant has potential to be grown on unused, under-utilized and marginal land and Relatively tolerant to drought and pest.Jatropha meal after oil extraction can be used as fertilizer or for energy production .Significantly detoxified Jatropha kernel meal can be used in production of bio-based industrial products like bio glue therefore it can be said as a FUTURE SUSTAINABLE FUEL

KEYWORDS: *jatropha curcas* , bio diesel, tolerant, sustainable fuel

VERMICULTURE BIOTECHNOLOGY SOCIO ECONOMIC DEVELOPMENT OF HUMAN HEALTH AND ENVIRONMENT BY THE USE OF EARTHWORMS**DEEPA JOSHI, GIRISH CHANDRA***Department of Agriculture , SGRRU, Dehradun, Uttarakhand- 248001*

A revolution is unfolding in 'vermiculture biotechnology' for achieving quicker and cheaper solutions to several environmental , economic and social problems plaguing the human society from sustainable waste management. The recovery of nutrients by modification of wastes like municipal solid waste , industrial solid waste, agricultural residues and animal wastes ,etc. is important for their management and for reducing environmental degradation. Recycling of organic wastes through vermicomposting biotechnology is an emerging trend as an "environmental sustainable" , "economically viable" and "socially acceptable" technology all over the world. Vermicomposting of solid wastes can divert 60-70 % MSW from landfills. Earthworms and their excreta (vermicast) are miracle growth promoters producing highly nutritive and health protective foods while also protecting crop plants from pests and diseases. Sir Charles Darwin wrote that ' no other creature on earth has done so much for mankind ' as the earthworms. Vermicomposting is a sustainable technique for solid waste disposal. Apart from abatement of environmental pollution, such reuse of organic wastes in agriculture helps in the improvement of various physical, chemical and biological properties of soil and thus helps in sustaining soil health. Despite the major advances have been made ,but there is still a need and scope to undertake investigations in this technology and identification of a group of microorganisms which have profound effects on maintaining soil health and increasing crop production. Vermiculture appears to be a novel sustainable technology for waste treatment which has a great future in the field of organic waste management.

TO STUDY THE INFESTATION OF MELOIDOGYNE JAVANICA IN OKRA**DEEPAK KUMAR AND K. K. VERMA***Department of Nematology, CCS Haryana Agricultural University, Hisar-125004*

Okra, *Abelmoschus esculentus* L. (Moench), belongs to the family Malvaceae is one of the warm season crop grown in the tropical and sub tropical regions of the world. Okra contains very high sodium content and is a rich source of vitamin A and B. Root-knot nematodes (*Meloidogyne* spp.) are major constraint in growing of okra crop successfully in tropical and subtropical regions, and infected plants remain stunted, exhibiting signs of nutrient deficiency and characteristics large irregular swellings on both primary and secondary roots. Root-knot nematodes are poikilothermic organisms and their development is usually dependent on temperature. Extensive research has shown that rates of *Meloidogyne javanica* embryonic and post-embryonic development, pathogenic level and life cycle are strongly influenced by temperature and relative humidity. The present investigation was conducted in screen house of Department of Nematology at Chaudhary Charan Singh Haryana Agricultural University, Hisar. Significant reduction in the plant growth parameters and increase of inoculum densities leads to increase in number of root-knots thereby increasing nematode population. The rate of nematode multiplication was reduced with the increase in the inoculum density of *M. javanica*. This might be due to the destruction of root system by the parasitism of root-knot nematode which led the competition for food and nutrition among the developing nematodes within the root system and also due to inability of juveniles to find out new infection sites for subsequent generation.

Keywords: *poikilothermic, inoculum, Meloidogyne* etc.

PROBLEMS OF HERBICIDE RESISTANCE IN WEEDS AND THEIR MANAGEMENT OPTIONS**AUTHOR DEEPAK KUMAR YADAV***Department of agronomy, Institute of agricultural sciences, BHU, Varanasi - 221005*

Weeds play an important role in reducing crop yield, if not managed properly. On an average, almost 1/3 of total crops produce are vanished due to the weed infestation (Rao *et al.*, 2018). Herbicide resistance is the inherited ability of plant or biotype to survive and reproduce following exposure to a dose of herbicide normally lethal to the wild type or weed resistance defined and simplified as decreased response the population of a weed species to a herbicide than what an expected or achieved earlier mainly because of long and continued application of the same herbicide. Total crop failure has also been reported due to weeds infestation in upland rice (Reddy and Reddy, 2013). Herbicide use increased more than thirteen-fold (from 16 to 217 million kg) between 1960 and 1981 as more U.S. farmers began to treat their fields with these chemicals. By 1980, more than 90-99% of the U.S. corn, cotton, and soybean area was treated with herbicides as compared to 5-10% of area planted in 1952 (Fernandez-Cornejo *et al.*, 2014). Over reliance on herbicides for weed control has led to rapid evolution of herbicide-resistant (HR) weeds. At present, the use of pesticides in India is quite low and estimated at 0.6 kg/ha as compared to global average of 3 kg/ha (Bhullar *et al.*, 2016). The most common cause of evolution of resistant weeds is by exerting selection pressure on weeds with the use of same herbicide (or herbicides with the same target site of action) year after year (Reddy and Jha, 2016). The resistance against herbicide was reported as early as 1957 against 2,4-D by *Commelinadiffusa* from Hawaii (Hilton, 1957). The first confirmed report was against triazine herbicide in groundsel (*Senecio vulgaris*), was reported in 1968 from U.S.A. In India, *Phalaris minor* developed resistance to Isoproturon during 1992-93 (Malik and Singh 1992-93). This is the most serious case of herbicide resistance in the world with total crop failure particularly under heavy infestation (2000-3000 plants/m²) (Kaur *et al.*, 2016). The herbicide resistance cases reported as follows in different countries - U.S.A. rank first followed by Australia and Canada, India stands at 34th position in case of number of resistant weed flora occurrence. There are currently 491 unique cases (species x site of action) of herbicide resistant weeds globally, with 254 species (148 dicots and 106 monocots). Weeds have evolved resistance to 23 of 26 known herbicide sites of action and to 163 different herbicides. Herbicide resistant weeds have been reported in 92 crops in 70 countries. There are more resistance reported from ALS inhibitor group, total 160 sp. (98 dicots and 62 monocots) followed by Photo system II inhibitors, total 51 sp. (51 dicots and 23 monocots) (<http://www.weedscience.org>, 2018). Accurate and timely diagnosis of the nature and level of herbicide resistance in a weed population and knowledge about the inherent resistance mechanism involved will greatly strengthen the efforts towards devising sound herbicide resistant weed management strategies. New technologies, especially, molecular tools revolutionizing herbicide resistance research. (Nandula, 2016). HR management cannot be attained by single method of approach but can be achieved as combination of weed management like prevention, cultural and mechanical practices with herbicide application with proper dose, method and time of application like IWM practices.

OPTIMIZATION OF FERTILIZER DOSES IN CITRONELLA (CYMBOPOGON WINTERIANUS L.) BASED INTERCROPPING SYSTEMS WITH KHARIF MAIZE AND BAJRA**DEEPAK KUMAR*, A.K. SHRIVASTAVA AND ADESH SINGH¹***Department of Agronomy, College of Agriculture, Chandra Shekhar Azad University of Agriculture & Technology, Kanpur (U.P.) India*

The field experiment was conducted at CSAUA&T, Kanpur with 09 treatment of cropping systems in different combinations viz., sole citronella, sole maize, sole bajra, citronella + Maize (100% RDF), citronella + Maize (75% RDF), citronella + Maize (50% RDF), citronella + bajra (100% RDF), citronella + bajra (75% RDF), citronella + bajra (50% RDF) in randomized block design with 3 replications. The soil of experimental field was sandy loam in texture with good irrigation and drainage facilities. Sole treatments were fertilized with recommended doses (100% RDF) for these crops and treated as control. The citronella crop (cv. Bio-13) was transplanted on 30 July, 2010 at 60 x 60 cm spacing. The *kharif* Maize cv. P-3441 (Hybrid) and Bajra (86M84) was planted on 10 July 2015 at 60 x 20 cm and 40 x 15 cm geometry, respectively. The *kharif* crops (Maize and Bajra) were harvested on 08 and 12 October 2015, respectively while, the citronella herbs were harvested during the experimental period on 16 September 2015. After harvesting of citronella herbs, distillation was done for oil extraction.

The results revealed that after harvest, organic matter and available nitrogen in the soil was highest in sole maize and intercropping of citronella+maize with 100% RDF and 75% RDF followed by Bajra sole and citronella+bajra intercropping with all the three fertilizer doses i.e 100%, 75% and 50% RDF, respectively. The available phosphorus (P₂O₅) was highest in citronella + maize intercropping system with 100% and 75% RDF fertility level, respectively. The available potash was decreased year by year but the highest potash was found in citronella sole followed by C+M 75% RDF followed by bajra sole (177.5 kg/ha) and C+M 50% RDF. Cultivation of citronella sole crop was superior over sole maize and sole bajra cropping system. In intercropping system, the highest citronella equivalent oil yield was found in citronella + maize 100% RDF followed by 75% and 50% RDF system, respectively. The highest net return was found in citronella + maize 100% RDF and B:C ratio highest is sole citronella 3.79 followed by C+M with 50% RDF intercrop system with B:C ratio 3.75.

STUDIES ON GENETIC DIVERGENCE IN BITTER GOURD (*MOMORDICA CHARANTIAL*.)**DEEPAK MAURYA*, V.B. SINGH, G. C. YADAV AND VEERENDRA KUMAR***Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad- 224 229, (U.P.), India*

The experiment was conducted during spring summer season, 2017 in Eastern Uttar Pradesh, to evaluate the nature and magnitude of genetic divergence among the thirty genotypes of bitter gourd were carried out by using Mahalanobis D² statistics. Thirty genotypes were grouped into 6 different non-overlapping clusters. Cluster III had highest number of genotypes (8) followed by cluster II (7), cluster V (6), cluster IV (5) and cluster I, VI (2) whereas cluster I and VI had only two genotypes.

The highest intra-cluster distance was observed for cluster VI recorded for (123.61) followed by cluster V (91.85), cluster I (69.08) and cluster II (62.75), cluster IV (47.92). The maximum inter-cluster distance observed between cluster III to cluster VI (231.577), which suggested that members of these two clusters are genetically very diverse to each other. The inter cluster values between cluster II to cluster VI (222.683), cluster II to cluster V (220.722), cluster V to cluster VI (205.629), cluster I to cluster VI (187.421), cluster III to cluster V (148.762), cluster II to cluster IV (134.414) and cluster I to cluster V (133.185) were very high.

The minimum inter-cluster distance was recorded in cluster I to IV (91.813) and cluster IV to V (104.356). Highest inter cluster distances, recorded indicated between two cluster pairs greater genetic divergence between the genotypes of those clusters, whereas, lower inter-cluster values between the clusters suggested that the genotypes of the clusters were not much genetically diverse from each other. The intra-cluster means for twelve characters in bitter gourd. Among 12 characters studied, average fruit weight (g) contributed maximum (27.82%) towards genetic divergence followed by fruit yield / plant (18.39%) and fruit length (12.64%) in bitter gourd. Ranking of genotypes based on intra-cluster mean performance for these characters which are major contributors of genetic diversity revealed its usefulness in selecting parents for heterosis breeding.

CANOPY MANAGEMENT IN “KING CHILLI” AT NORTH EASTERN CONDITIONS (*CAPSICUM CHINENSE* JACQ.)**DEEPAK RANJAN PRADHAN^{1*} AND ASHOK KUMAR MEENA²**^{1,2}*Department of Horticulture, Assam Agricultural University, Jorhat-785013*

King chilli (*Capsicum chinense* Jacq.) is wonderful gift of nature as its fruit is one of the hottest chillies in the world and at the same time it possesses a pleasant and palatable aroma. It is also called as “Naga Jolokia” Bih Jolokia, Ghost chilli pepper and *Bhut Jolokia* is extensively cultivated in North Eastern region and cannot be grown in any other parts of India. In 2007, Guinness World Records certified the *Bhut Jolokia* the world's hottest chilli pepper with more than 1 million Scoville Heat Units (SHUs), 401.5 times hotter than classic Tabasco sauce with a hotness of 2,500-5,000 SHUs. Canopy management is a practice that balances the reproductive and vegetative processes of the plant. In an experiment in which King chilli plant was trained to single stem, double stem and multistem by using bamboos. It was found that plants with double stem or multistem plant produced more fruits as compared to untrained and single stem trained plant. The double stem trained plants get more space for the proper growth of the fruits and they bear more number of fruits and also they develop excellent colour of fruit. Also, this system is more effective in case of greenhouse condition as compared to open field condition.

Key words: Canopy management, Training, Growth, Greenhouse

INFORMATION TECHNOLOGY PENETRATION IN AGRICULTURE IN AGRA (UTTAR PRADESH)**DEEPIKA TIWARI¹ JAGADISH ADITYA DINAKAR²***Institute of Agribusiness Management, Bikaner, Keywords: IT Penetration, Smart Phones*

Information and agriculture were considered to be different with each other in previous years but now the scenario has changed. Today information is required in every area of agriculture. In the area of agriculture, the potential of information technology (IT) can be identified broadly under two heads: (a) it contributes directly to agricultural productivity and (b) and indirectly to empower farmers so that they can take information and make decisions based on the information. This will help farmers to face market situations; It acts like decision support system for farmers. In developed countries, the agricultural productivity is very high because of uses of IT information in precision farming. Agriculture output is increasing in developed countries with the use of remote sensing, various kinds of satellite technologies, agronomic practices etc. The farmers having large area of land are using this kind of approach. Farmers are also take up this kind of activity as an corporate approach. Today, in India the benefits of IT in agriculture are exploited and farmers are not using because of awareness. Farmers are still using traditional practices, that is why their production is very less. The Indian farmer urgently requires timely and reliable sources of information inputs for taking decisions. To remain successful in market, farmers should incorporate these

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

IT related practices in agriculture. This paper examines the extent of usage of smart phone by farming community, their socio-economic group and also examines what kind of information are disseminated by companies to farmers

EVALUATION FOR COLIFORM CONTAMINATION OF DIFFERENT HILLY SPRING WATER SOURCES IN AND AROUND THE CITY NAINITAL, WESTERN HIMALAYA

DEVENDRASINGH BISHT* AND DEEPAK KUMAR ARYA

Department of Zoology, D.S.B. Campus, Kumaun University, Nainital 263002, Uttarakhand, India

Nainital is an internationally recognized tourism hot spot lying at the elevations ranging from 1938-2611 m above sea level within the state of Uttarakhand in the Western Himalayan region of India. The daily water requirements for the local need depend solely on natural lake in the basin while few other water springs in the hilly regions of the city also provide adequate fresh water sources for drinking purposes. Traditionally, spring water is considered clean and pure due to the natural filtering that occurs during infiltration and its movement through shallow and deep aquifers. However, the possibility of contamination by humans and wildlife is always there. Keeping this in view, the present study aimed to evaluate coliform contamination of fresh water springs and their suitability for drinking and other domestic purposes. Water samples were collected aseptically on a monthly basis in sterilized containers from ten hilly springs in the study area from January to June, 2018. The samples were analyzed for microbial parameters like total plate count (TPC), and presumptive test to detect the presence of coliform bacteria in water samples. Of the total samples evaluated, water samples collected from two water springs exhibited green metallic sheen on EMB indicating the presence of fecal coliform bacteria i.e., *E. coli* rendering the water sample as contaminated. This study provides updated information on the spring water contamination in hilly areas which seeks an immediate action in order to improve the bacteriological quality of these mountainous spring water sources.

Keywords: Spring, drinking water, *E. coli*, Eosin Methylene Blue.

PLANT QUARANTINE IN INDIA

DHARM BEER, RAVINDRANATH NISHAD, SURYA PRATAP SINGH, RAVISHANKER, AJEET KUMAR

N. D. University of Agriculture and Technology, Kumarganj, Faizabad-224229 (U.P) India

To prevent the entry, establishment and spread of exotic pests in India as per the provisions of The Destructive Insects & Pests Act, 1914. These are documents issued by an official of an exporting country, or country of re-export, attesting to the freedom from pests and admissibility into the destination country for specific plants or plant products. PRA (pest risk analysis) is a process of investigation, evaluation of information and decision making with respect to certain pests, that starts once it is known or determined that this pest is a quarantine pest. 1st Quarantine work started in 1879 in Fiji and in 1900's. The Agricultural Quarantine started again in Fiji. Plant quarantine is a technique for ensuring disease and pest free plants, whereby a plant is isolated while tests are performed to detect the presence of a problem (Plant quarantine Wikipedia). Two new species of whiteflies (Hemiptera: Sternorrhyncha: Aleyrodidae: Aleyrodinae) intercepted in quarantine on plants from Asia. Two new species of whiteflies are described and illustrated based on specimens intercepted at US Ports of entry. *Aleurolobus tomkinsae* Dooley & Smith *sp. nov.* was intercepted on the leaves of *Berbera koenigii* Linnaeus (Rutaceae) from India and Sri Lanka and on *Magnolia* L. (Magnoliaceae) from Thailand. *Asialeurodes lateropapilliformis* Dooley & Smith *sp. nov.* was intercepted on the leaves of *Syzygium*. Browne ex Gaertn (Myrtaceae) from Indonesia. Head Quarter Directorate of Plant Quarantine and storage Faridabad Started in year 1946. Quarantine is an important protocol for International and National food trading. To prevent dumping of low quality goods in the country and protecting the nation from introduction and spread of exotic pests and diseases.

WEEDS THREAT TO AGRICULTURE PRODUCTION AND SOIL HEALTH

DHARMINDER*, VISHAL KUMAR, A. K. DEVEDEE, R.K.SINGH, AVINASH PATEL, ABHISHEK SHORI AND SUDHANSHU VERMA

Department of Agronomy, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi 221005, UP, India

Weeds are a perennial problem with the farmers. They reduce yield and quality of crops substantially. Weeds are identified as a major biological constraint that hinders attainment of optimal productivity in major crops. Weeds were reported to reduce rice yields by 12 to 98%, depending on type method of rice establishment. Weedy rice (*O. sativa*) has become a serious problem in India, and its spread is largely through the use of contaminated rice seeds. In today's scenario single weed control approach may not be able to keep weeds below an economic threshold level. The escalating problems of herbicide persistence and resistance in weeds associated with the herbicide use have led to the emphasis on integrating herbicides with the physical, cultural, and biological weed management practices for reducing the reliance on herbicides alone. Excessive use and incorrect time of herbicides application may lead to soil degradation and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

environmental problems. Herbicide also affecting soil flora and fauna. They not only competing with the desired plants for the resources (sunlight, nutrients, water, and space) but also provides shelter to hosts and vectors for plant pathogens, giving them greater opportunity to infect and degrade the quality of produce apart from significant reduction in yield of field crops. In India, the highest loss (33%) is caused by weeds, followed by pathogens (26%), insects (20%), storage pests (7%), rodents (6%) and others (8%). The data show that weeds reducing the yield saliently to greater extent hence it is today's most urgent requirement to be monitored continuously (weed flora) to assess the emerging weed problems and plan weed management strategies accordingly.

Key Words: Weed, Herbicides, Weed control, Integrated Weed Management etc

RECENT DEVELOPMENT IN POMEGRANATE

DHEERAJ YADAV, ABHINAV KUMAR, ATUL YADAV AND SNEHA SINGH

Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad

The pomegranate has been grown since ancient times for its delicious fruits and as an ornamental garden plant for its red, orange or occasionally, creamy yellow flowers. The pomegranate (*Punica granatum* L.) belongs to the puniceae family. It is also known as the *Chinese apple* or *Apple of Carthage* or *Apple with many seeds*. Pomegranate is known as a super fruit of next generation and is a native of Iran to Himalayan region and is extensively grown in Iran, Spain, India and USA as well as in most Near and Far East countries. In India, pomegranate is considered as a crop of the arid and semi arid regions because it withstands different soil and climate stresses. It thrives best under hot dry summer and cold winter provided irrigation facilities are available. Pomegranate fruits are irregular round in shape with coriaceous rinds that vary from yellow, green or pink to bright deep red, depending on the variety and stage of ripening. Pomegranate is a very promising and emerging crop for its refreshing arils, juice and its chemo preventive properties having medicinal value. commercial farming of the pomegranates globally, due to the potential health benefits of the fruit such as its high antioxidant, anti-mutagenic, anti-hypertension activities and the ability to reduce liver injury.

Keywords - ancient, semi arid regions, commercial farming, high antioxidant etc

TELOMERASE: A CELLULAR REVERSE TRANSCRIPTASE

DINESH KUMAR SHARMA AND ANIRUDH KUMAR SHARMA

Department of Microbiology, C.C.S. University, Meerut, 250004, India, Department of Horticulture, J. V. College, Baraut

Telomerase, a cellular reverse transcriptase, has been identified as ribonucleoprotein enzyme complex that maintain telomere length in human stem cells, reproductive cells (gametes) and cancer cells by addition of guanine-rich repetitive sequences onto the telomeres. Telomeres are repetitive DNA sequences at the ends of linear chromosomes. Human telomeres are specialized chromosomal end structures composed of TTAGGG repeats. Telomere length represents a balance between the loss of terminal telomeric repeats, which occurs during cell division with incomplete DNA replication, and the addition of telomeric repeats by the unique RNA-dependent DNA polymerase telomerase. Telomerase and telomeres have been shown to be involved in the control of cell proliferation, the regulation of cell senescence and the unlimited proliferation capacity of malignant cells. They function to protect chromosomes from degradation, fusion and recombination. Since the termini of linear molecules are replicated only in the 5'-3' direction by conventional DNA polymerases and require an RNA primer to initiate DNA synthesis, the removal of the RNA primer results in DNA loss (approximately 50 nucleotides) with each cell division. The gradual and progressive telomere shortening at each replicative cycle is associated, through the activation of pRB and p53 pathways and genomic instability, to the replicative senescence, a non-dividing state and widespread cell death. This review aims on the structure and function of the telomerase-telomere complex and its altered behavior leading to disease, mainly cancer and aims to summarize important results in the rapidly moving field of telomeres and telomerase. Although telomerase therapeutics are not approved yet for clinical use, we can assume that based on the promising in vitro and in vivo results and successful clinical trials, it can be predicted that telomerase therapeutics will be utilized soon in the combat against malignancies and degenerative diseases.

INCIDENCES OF REPEAT- BREEDING AT ORGANIZED DAIRY FARMS IN CATTLE.

DINESH MAHTO AND SHOBHARANI

Krishi Vigyan Kendra, Gandhar (B.A.U, Sabour) Jehanabad, Bihar: 804432

The present study was conducted on the animal of Military Dairy and organized farms at Ranchi. The general and breeding history and animals, presented for Gynecological checkup were recorded in respect of age of animal, number of calving, day past from last calving, nature of estrus cycle, number of insemination done without conception it's were noted. Animals observe to be in estrus for the first or

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

second time were considered as normal or fresh animal, and those coming to estrus. For third time or more after insemination were taken as repeat breeding animals. A total of 144 cows were selected. Observed, that the highest incidence of repeat breeding (23.52%) was recorded during the month of February and the lowest (11.90%) during the month of June. The overall incidence of repeat breeding out of total number of 483 cases examined was 16.82 percent. The highest incidence of repeat breeding was observed during monsoon (23.80%) and lowest during summer (13.63%) season. The highest incidence of (42.85%) was observed in first calvers.

Key words: Incidences, Repeat breeding, Cattle, infertility and Season

EFFECT OF DIFFERENT SOWING DATE ON WHEAT.

1*DINKLE RAINA 2*GEETAKANDPAL

Department of agronomy, School of agriculture, Lovely Professional University, Phagwara, 144411 Punjab, India, , Department of Agronomy, Lovely Professional University, Phagwara, 144411, Punjab, India

Wheat is a dominant crop. Mainly grown in temperate season used for human food and livestock feed. It is an important cereal crop next after rice. Wheat is grown on more land area than any other food crop. Wheat plant has long slender leaves and stem that are hollow in most varieties. The main aim of this research is to test the hypothesis that the impact of different dates of sowing on crop growth and yield of wheat. Best sowing dates provide favorable temperature to obtain maximum yield. Three varieties of wheat HD 3086, PB550 & HD2967 was selected and cultivated in Phagwara belonging to Punjab region. Early and late sowing is done to grow the wheat crop of different varieties at 10 days interval. Early sown crop mature early than those sown later. Early sown crop reduced from the different types of injuries like drought and diseases other environmental factor like rainfall, temperature humidity Dose of fertilizers like UREA AND DAP are used in 18 plots to enhance the yield and growth of wheat. On the behalf of this research work we conclude that the different dates of sowing like early sowing and late sowing give crop growth and yield of wheat.

KEY WORDS: Crop; Wheat; Variety; treatment;

MEDIA ALTERNATIVES FOR PRODUCTION OF BANANA (*MUSA CAVENDISH* L. CV.G-9) THROUGH TISSUE CULTURE

DIPAK KADAM¹, SHIVAJI LAVALE² CHHATRE A. A.³, AND NALINI SHINDE⁴

¹Junagadh Agricultural University, Junagadh-362001, ²International Crops Research Institute for Semi-Arid Tropics, Hyderabad, India

^{3&4} Lokmangal College of Agricultural Biotechnology, Solapur. MPKV, Rahuri

The present investigation on Media Alternatives for Production of Banana (*Musa cavendish* L. CV.G-9) through Tissue Culture” was carried out during the year 2015-2016 at Plant Tissue Culture Laboratory, Lokamangal College of Agricultural Biotechnology, Solapur. The data was analyzed using Analysis of variance (ANOVA) in Microsoft Excel at 5% significance level.

The low cost alternative components of tissue culture media were evaluated for their potential to supply nutrients and to support growing explant of Banana cultivar in vitro for their cost effectiveness against conventional high cost media. The Murashige and Skoog (MS) salts and sucrose were replaced by vermicompost (50 g/L), table sugar (30 g/L) and coconut water (70 ml/L), and agar was replaced by filter paper, sand and wheat floor. The conventional MS medium supplemented with 30 g/L sucrose and 8 g/L agar was used as control. A banana cultivar was regenerated on control and combinations of alternative components. MS salts in combination with filter paper as solid matrix was found as very efficient for shoot induction, multiplication and root formation with reducing the cost upto 58.13 %. Vermicompost as nutritive source was found to be very effective in reducing cost of media per plantlet. Table sugar reduced the cost of carbon source drastically by 97 %. Use of such alternatives can reduce the cost of media thereby minimizing the production cost of tissue cultured plantlets.

Key words: Media alternatives, banana, tissue culture

EFFECT OF DIFFERENT IRRIGATION SYSTEM ON GROWTH AND DEVELOPMENT OF WHEAT-CHICKPEA INTERCROPPING

Diptanu Banik, Hina Upadhyay, Puyam Binita Devi and Mayur Darvhankar, School of Agriculture Lovely Professional University, Phagwara, Punjab - 144411*

A field experiment was conducted to determine the growth, development and productivity in Wheat-Chickpea inter-cropping under different irrigation conditions. The experiment was done in 2017-2018 on a sandy loam soil of Lovely Professional University, Jalandhar, Punjab. As the experiment was mainly depends on different irrigation quantity of the sole Wheat-Chickpea crop and intercropping of wheat-chickpea showed immensely variations in different treatments. The highest plant height, leaf size and no of tillers found in the T₂

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

during the experiment. The best Irrigated treatment was T₂: RDF + Less irrigation which showed different variation on the growth and development parameters.

Key Words- Chickpea, Irrigation, Intercropping, Wheat

PREFERRED MODE OF PRESENTATION: ORAL**BIOLOGICAL MANAGEMENT OF *PHYTOPHTHORA* BLIGHT OF TARO *COLOCASIA ESCULENTA***

DIVYA BHANDHARI

CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) - 176062

Colocasia roots carry more calories than potato (100gm of root provide 112 calories) and also is much more superior than other tuber crops and potato in many constituents such as protein, minerals, fiber, phosphorus, iron. *Phytophthora colocasiae* cause leaf blight of taro. The genus is of great historical importance as well as of economic importance. The optimum temperature for growth is 20°C, above 29°C temperature, hyphae die. Asexual and sexual reproduction takes place through zoospore and oospore respectively. Colocasia blight causes heavy loss in yield in kharif season especially in moist places. It is primarily a foliar pathogen but also affects petioles and corm. On leaf numerous light to dark brown spots are formed. The disease appears constantly in epidemic form due to ability of pathogen to survive as soil and seed borne, as a result this disease become difficult to manage with cultural, host resistance and chemical means. Thus, biological management has gained importance as *in vitro* screening of antagonistic microorganism and *in vivo* evaluation of bioagents have been done. Fungal and bacterial microorganisms have been isolated from phylloplane or rhizosphere soil of colocasia and tested *in vitro* for antagonism. *In vivo* bacteria like *Streptomyces albidoflavus* and *S. diastaticus* and among fungi, *Botrytis cineria*, *Trichoderma viride*, *T. harzianum*, *Gliocladium virens* have also seen to reduce its incidence. Rhizobacteria isolated from colocasia rhizosphere soil have been reported to have the ability to completely inhibit the growth of *P. colocasiae* *in vitro*. So, biological management of colocasia blight would greatly help in reducing its severe attack which ultimately help to get good yield.

KEYWORD: Phytophthora, Biological management, colocasia, bioagents, antagonistic

EFFECT OF MICRONUTRIENTS ON SOIL PRODUCTIVITY AND CROP GROWTH

DIVYAGAU¹* AND GANPAT LOUHAR²

¹Department of Soil Science, CCSHAU, Hisar, 125004, Haryana, ²Division of Soil Science and Agricultural Chemistry, IARI, New Delhi, 110012

Soil plays a major role in determining the sustainable productivity of an agro-ecosystem. The sustainable productivity of a soil mainly depends upon its ability to supply essential nutrients to the growing plants. The deficiency of micronutrient has become a constraint to productivity, stability and sustainability of soils. The importance of micronutrients has been realized during the past four decades when widespread micronutrient deficiencies were observed in most of soils in our country, intensive AICRP on secondary, micronutrients and polluted elements in soil and plants, Zn deficiency appeared to be widespread with 49%, B deficiency is next to Zn in order is 33%, 7% and 4% respectively. Micronutrient contents of soil and their availability to plant are assessed by the mineral present and weathering processes. Uptake of micronutrient is affected by the presence of major nutrients due to either negative or positive interactions. Different interaction between macro and micronutrients such as positive interaction of N and Fe, P and Mo, Mo and Zn, and negative interaction between Zn and P. thus, indiscriminate use of macronutrients may affect uptake of micronutrients. Plant uptake their nutrients mostly from soil. It is well known that the optimum plant growth and crop yield depends not only on the total amount of nutrients present in the soil properties like: soil texture, organic carbon and calcium carbonate, cation exchange capacity, pH and electrical conductivity of soil. Micronutrients play an important role in increasing crop yield through their effect on the plant itself, nitrogen fixing symbiotic process and effective use of major and secondary nutrients.

Keywords: micronutrients, sustainability, stability, productivity.

MANAGEMENT OF SHOOT AND FRUIT BORER IN BRINJAL (*SOLANUM MELONGENA*) UNDER SOUTH WESTERN SEMI ARID ZONE MATHURA.

DR BRAJ MOHAN SMS HORTICULTURE AND DR YK SHARMA

SMS Ag. Extension KVK DUVASU Mathura

Brinjal is an important vegetable crop grown in Mathura. The high incidence of shoot and fruit borer reduces its yield drastically. Caterpillars of fruit borers feed inside the tender shoots before flowering and cause wilting of the affected shoots. Grown up caterpillars bore into the fruits. KVK conducted field trial in the year 2017 on 6 locations with 11 farmers covering an area of 4 hectares to manage the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

menace of shoot and fruit borer. Cypermethrin 25% EC a systemic pesticide was used/sprayed on crop before flowering i.e. at 45 days followed by another spray after 15 days of 1st spray i.e. 60 days. The pesticide was found highly promising which controlled upto 93% Catterpillars, while under local practice it was found control/manage 66% shoot and fruit borer, thus, recorded an increase in control of this insects by 40.90%. The 18.57 % increase in yield of brinjal was recorded when compared with local check. This also helped to again economically to the farmers.

EFFECTS OF SIMULATED ACID RAIN ON PLANT, GROWTH COMPOENENTS OF GREEN GRAM (*VIGNA RADIATA LINN WILLZECK CVK 851*) AND BANKLA (*VICIA FABA LINN CV ALL GREEN*)

SARITARANI* AND MRS. ANITA CHAUHAN

Department of Botany SPC College Baghpat-250622, (U.P.) India

The present study has been undertaken to study the effects of Simulated Acid Rain on two important food crops grown widely in India. Most of the investigations on the effects of acid precipitation made so far are based on local vegetation. The main objective is to characterize a relative growth and yield response of these leguminous crops to different concentration of simulated acid rain. The legumes are important food crops for human beings as they are good source of protein, carbohydrate and fats. This research studied the effect of Simulated Acid Rain on plants, growth components of Green Gram and Bankla. Green Gram [*Moong Vigna radiata linn willzeck cvk 851* and Bankla *Vicia faba Linn cv all green (Broad bean)*] are belong to Leguminaceae sub family Papilionaceae.

Simulated Acid Rain was prepared with different concentrations of H₂SO₄ and HNO₃ in the ratio 7:3. The plants were exposed to simulated acid rain of pH 2.5, 3.5, 4.5 and 5.5 with control. The morphological changes including plant height, days and time taken in flowering (No, of days), number of leaves were recorded. All the morphological parameters taken in this study showed decrease trend with decrease pH (increase in acidity). The yield of *Moong* and *Bankla* decreased due to acidic rain.

MOLECULAR MARKER-ASSISTED VEGETABLE CROP IMPROVEMENT

DURGA PRASAD MOHARANA^{1*}, ANAND KUMAR SINGH¹, AND D. R. BHARDWAJ²

¹Department of Horticulture, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221 005, Uttar Pradesh, India ,

²ICAR-Indian Institute of Vegetable Research, Varanasi-221 305, Uttar Pradesh, India

After a prolonged decline, world hunger appears to be on the rise again. The estimated number of undernourished people increased to 815 million in 2016, up from 777 million in 2015. With the continuing detrimental climate change and shrinking agricultural resources, it is a hard time to offer the world not only food security but also nutritional security. To achieve this paramount task, conventional plant breeding cannot be enough on its own. An amalgamation of conventional plant breeding with the marker-aided technology will be capable to sustain the global demand. Vegetables being assigned with the status of protective foods should be given high priority for improvement as it will act as one of the major key factors in achieving this daunting goal. A molecular marker (DNA marker) is a fragment of DNA revealing mutations/ variations, which can be used to detect polymorphism between different genotypes or alleles of a gene for a particular sequence of DNA in a population or gene pool. The integration of molecular markers in plant breeding activities has given rise to the new discipline described as “smart breeding,” “molecular breeding,” or “marker-assisted breeding”. As in a plant breeding program, a lot of plants have to be evaluated for a number of markers within a relatively short period of time. The high cost of marker genotyping is considered as one of the main factors limiting the wide spread adoption of marker technology in routine breeding programs. Therefore, the molecular marker systems should be amenable to high throughput, and their genotyping cost should be reasonably low. In a long run, conventional plant breeding in conjunction with the potentials of marker technology has a bright prospect for improvement of vegetable crops.

Keywords: Vegetables, nutritional security, molecular markers, marker-assisted breeding

ASSESSMENT OF GENETIC VARIABILITY AND DIVERGENCE IN FIELD PEA (*PISUM SATIVUM L. VAR. ARVENSE*) GENOTYPES FOR IDENTIFICATION OF MOST DIVERGENT LINES.

DURGA PRASAD*, SHIVANATH, KANHAIYA LAL, AJEET JAISWAL AND VISHWANATH PRATAPYADAV

Department of Genetics and Plant Breeding, Narendra Deva University of Agriculture and Technology Kumarganj Faizabad 224229 (U.P.) India

The present investigation was conducted at Genetics and Plant Breeding Research Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) in Augmented Block Design during *Rabi* 2016-17, using ninety genotypes with four check varieties viz. Rachna, HUDP-15, HFP-8909 and HFP-4 to estimate extent of genetic divergence, genotypic coefficient of variance and phenotypic coefficient of variance for different traits. For this purpose data on various quantitative characters was taken out. Analysis of

variance revealed highly significant differences among all the genotypes for majority of traits except pod length, this indicates good amount of genetic variation in the experimental material under investigation. Moderate to high level of genotypic and phenotypic coefficient of variance were observed among the genotypes. Phenotypic coefficient of variance was found slightly higher than genotypic coefficient of variance this indicates very less environmental influence on the expression of the characters. Higher estimates of GCV (22.84) was recorded for pod length (cm) followed by number of pods per plant (20.96), number of primary branches per plant (20.78) and plant height (17.40) this indicates that pod length, number of pods per plant, number of primary branches per plant and plant height may be utilized as selection parameters. Analysis of genetic divergence through Non-hierarchical Euclidean cluster analysis includes TOCHER's and WARD methods. Through the WARD's method all the genotypes were grouped into 10 non-overlapping clusters in which cluster number IV and X were found largest including 12 genotypes while cluster IX was found smallest having 2 genotypes namely Pant P 223 and NDP 14-11. The higher inter cluster distance was observed between cluster number II and VIII (84.837) and between cluster II and V (75.302), this indicates that the genotypes belonging to these clusters are more genetically divergent from each other and inter-mating between such genotypes would produce more heterotic F_1 progeny. On the basis of overall investigation genotypes such as KPMR 936, IPLK 112, EC 384275, Prakash, KPF 1036 and Aman were identified as most divergent.

BIOFERTILIZERS: A NON-CHEMICAL SOURCE OF PLANT NUTRIENTS FOR SUSTAINABLE AGRICULTURE

DURGESH SINGH, ASHEESH CHAURASIYA AND SWARAJ KUMAR DUTTA

Department of Agronomy, BAU, Sabour, Bhagalpur- 813210

Biofertilizers are simply selective strain of beneficial soil microorganisms which apply either by seed treatment or soil application and act as a source of plant nutrients at very low cost. Special feature of these microorganisms are sustainability and eco-friendly action. After application, multiplication of microorganisms occurs which further generate plant nutrients in the soil or rhizosphere for plant use. Biofertilizers are help in recycling of nutrients within the components of environment. It provides "eco-friendly" organic agro-input and it can be expected to reduce the use of chemical fertilizers and pesticides, thus promote organic farming for sustainable agriculture. The use of biological inputs such as N and P-fixing bacteria, mycorrhiza or others are also able to maintain the biological, physical and chemical condition of soil. Soil act as a living system only because of microbial population present in it and without this soil unable to produce food. In recent years, biofertilizers have emerged as a promising component of integrating nutrient supply system in agriculture. Bio-fertilizers could be efficient to increase the growth, yield and quality of agricultural products with very less input cost. Soil microbes are also play some important role in many critical ecosystem processes, including nutrient cycling and homeostasis, decomposition of organic matter etc. Thus biofertilizers can be a better option for sustainable production system if we use it according to the proper methods and precautions.

EMERGING CROPS, NEW CULTIVARS AND VARIETIES FOR SUSTAINABILITY MAGNET OUT SNAPPEAS

ESHANEE, 'SHIVANI CHAUHAN, 'HARNOOR KAUR DHILLON, 'SHUBHAM KUMAR, 'SUNIL KUMAR, 'PRIYANKA AND 'BHALLAN SINGH SEKHON

CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) 176062

Magnet out is a French word meaning 'eat all' and edible pod peas are growing popular worldwide as a new crop for its whole eaten pods. This crop is cool season oriental vegetable which shares the cultivation pattern with the garden pea. They consist of snow peas (*Pisum sativum* var. *macrocarpon*) and sugar snaps/ snap peas (*Pisum sativum* var. *saccharatum*) which can be eaten whole as plump pods and seeds usually by removing the strings along the edges. Snap peas lack the pod parchment or fibre which makes their pod edible and easy to use. These peas are mildly flavoured and may be eaten raw, as salads, lightly boiled, steamed, used in 'stir-fry' and other dishes. They can be grown in varied agro climatic conditions but produce best yields and quality in cool and moist growing conditions. Whole pod edible peas are popular in USA, European countries, China, Japan and in South East Asian countries. In India, in the recent years, it is becoming popular and there is a tremendous scope for its spread as it has rich nutritive value especially Vitamin C, processing potential, crop use efficiency as whole pods are eaten and easy cultivation. Also it has great potential for export and is potential crop for India's economy. There are no final figures available for snow pea cultivation in India. Owing to diverse agro climatic conditions in India snap peas have an edge for round the year cultivation. Especially in hilly areas edible pod peas as an additional off season crop which has demand in urban areas can provide profitable returns to the growers.

Keywords: edible pod peas, export, processing, snap pea, snow pea

ROLE OF BIO-FERTILIZER IN ORGANIC VEGETABLE PRODUCTION**F.A. KHAN, S. NARAYAN, AJAZ A MALIK, K. HUSSAIN, ASTHA¹ AND M. AMIR²***Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar 190025, Distt. Srinagar (J&K)*¹CSAUAT, Kanpur; ²NDUAT, Faizabad

The increased crop production for exponentially growing population puts considerable pressure on land and other natural resources of the world causing damage to the ecological base of agriculture and serious socio-economic problems. The replenishment of huge nutrients lost in crop removal through the use of chemical inputs is not a sound advice as their use on a long run has been found to decelerate the biological activities in the soil causing impaired soil health. Consequently, increasing awareness is being created in favors of organic farming which has emerged as an important priority area globally in view of the growing demand for safe and healthy food and long term sustainability and concerns on environmental pollution associated with indiscriminate use of agrochemicals. Biofertilizers or microbial inoculants can be generally defined as preparations containing live or latent cells of efficient strains of nitrogen fixing, phosphate solubilising or cellulolytic microorganisms used for application to seed, soil or composting areas with the objective of increasing the extent of the availability of nutrient in a form which can be easily assimilated by plants. Biofertiliser are the low cost source of plant nutrients, eco-friendly and have supplementary role with chemical fertilizers. They are bacteria, algae & fungi and may broadly be classified into two categories viz. Nitrogen fixing like *Rhizobium*, *Azotobacter*, *Azospirillum*, *Acetobacter*, Blue Green Algae & *Azola* and Phosphorous solubilisers/ mobilisers like PSM & Mycorrhizae. Recently, the Potash mobilisers like *Frateruria aurentia*, Zinc & Sulphur solubilisers like *Thiobacillus species* and manganese solubiliser fungal culture like *Pencillium citrinum* have also been identified for commercial operations. These new strains would also address the issue of 'Fertilizer Use Efficiency' and enhance the efficacy of bio-fertilizers. Now bio-fertilizers are considered as essential components of organic farming and play vital role in maintaining long term soil fertility and sustainability by fixing atmospheric dinitrogen (N=N), mobilizing fixed macro and micro nutrients or convert insoluble P in the soil into forms available to plants, there by increases their efficiency and availability. Bio-fertilizers are one of the best modern tools for agriculture. It is a gift of our modern agricultural science. Biofertilizers are applied in the agricultural field as a supplement to our conventional fertilizers like compost, household wastes and green manure as conventional fertilizers are not as effective as chemical fertilizers. Vegetable cultivation is an important area of agriculture which provide a rewarding income to the growers and helpful in mitigating the malnutrition problem. However, they are heavy feeder of nutrients wherein chemical fertilizers need to be replaced or supplemented by organic and biofertilizers. Use of organic farming system in vegetable production is discussed.

NUTRACEUTICAL VALUE OF SPICES***G. CHANDRA MOHAN REDDY, R.K. GOYAL***Department of Horticulture, College of Agriculture, CCS Haryana Agricultural University, Hisar-125004, Haryana, India.*

Spices are mysterious food adjuncts that have been used as flavoring and coloring agents and as preservatives for thousands of years. Spices have also been documented to own medicinal properties and their use in traditional systems of medicine has been on record for a long time. The nutritional, anti-oxidant, anti-microbial and medicinal properties of spices have far-reaching implications. With the advancement in the technology of spices and on knowledge of the chemistry and pharmacology of their active principles, their health benefit effects were investigated more thoroughly in recent decades. Spices used as a Nutraceutical have great scope for improving human health as well as act as pharmaceutical without ant side effects compare to synthetic drugs.

Key words: Spices, Nutraceuticals, Pharmacology, Anti-oxidant.

A REVIEW ON-INFLUENCE OF ANTITRANSPIRANTS (ATS) IN VEGETABLE CROPS**G. KOTESWARARAO^{1*}, M. SURENDRA BABU², V. SRAVANI³, M. SINDHUJA⁴**^{1&2}Dept. of Vegetable Science, ⁴Dept. of Floriculture & Landscape architecture, ASPEE College of Horticulture & Forestry, Navsari Agricultural University, Navsari, Gujarat, 396450, ²Dept. of PSMA, KAU, Thrissur, Kerala, India

Water is the most abundant compound found in nature and is the most limiting factor in agricultural production. More than 98% of water is lost in the form of transpiration and evaporation. Transpiration is the loss of water from aerial parts of plants in the form of vapor, which is also known as 'Necessary Evil'. It takes place through lenticels, cuticle and stomata. Transpiration is affected by both external and internal factors. Water is a scarce commodity and with the expansion of agriculture, water conservation measures are becoming more important particularly chemical manipulation of transpiration with antitranspirants. Antitranspirants are chemicals sprayed on transpiring plant surfaces with an attempt to reduce water use by reducing transpiration. Depending upon their mode of action, they are stomatal closing type, film forming type, reflectance type and growth retardants. Antitranspirants should have some of the ideal

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

properties like non toxic, cheap, stable, long lasting in their effectiveness and they should have some of the assured benefits. Several researchers reported that antitranspirants not only reduce the water loss but also they improve the physiological, disease resistance, quality and yield aspects in many vegetable crops.

Keywords: Antitranspirants, ATs, Vegetables, Growth, Yield

EFFECT OF BORDER CROPS, MICROBIALS AND BOTANICAL ON CHICKPEA POD BORER, *HELICOVERPA ARMIGERA* (HUBNER)

G. M. Golvankar, V. S. Desai, S. K. Mehendale, K. V. Naik and S. D. Desai, Department of Agril. Entomology, College of Agriculture, Dapoli., Balasaheb Sawant Konkan Krishi Vidyapeeth, Dapoli 415712, Dist- Ratnagiri (M.S.)

The present experiment was conducted to study the effect of border crops, microbial and botanical on chickpea pod borer, *Helicoverpa armigera* (Hubner). There were total two sprays taken. On three days after first spray the treatment combinations, Maize + Btk and no border + Btk recorded zero larvae per five plants and found to be best treatments. On three days after second spray the treatment combinations Maize + Btk, Marigold + Btk, Sorghum + Btk, no border + Btk, Sorghum + HaNPV 500 LE ha⁻¹, Maize + *B. bassiana*, Maize + *M. anisopliae*, Sorghum + *M. anisopliae*, Marigold + Azadirachtin, Sorghum + Azadirachtin and no border + Azadirachtin recorded zero larvae per five plants and were found to be best treatment combinations. Three days after second spray the treatment combinations no border + Btk, Sorghum + HaNPV 500 LE ha⁻¹, Maize + Btk, Marigold + Btk, Maize + Azadirachtin and no border + Azadirachtin recorded least per cent pod damage and were at par with each other. At 7 days after second spray the treatment combinations no border + Btk, Sorghum + HaNPV 500 LE ha⁻¹, Maize + Btk, Marigold + Btk, Maize + Azadirachtin, no border + Azadirachtin and Sorghum + Btk recorded lowest per cent pod damage and were at par with each other.

Keywords: *Helicoverpa armigera*, microbial, botanical, chickpea, Trap crop, etc.

SOIL SALINITY: A SERIOUS ENVIRONMENTAL ISSUE FOR PLANT GROWTH AND MICROBIAL TOOL FOR ITS ALLEVIATION

GAGANDEEP*, RAMPRAKASH, RAKESH KUMAR

Department of Soil Sciences, CCS Haryana Agricultural University, Hisar-125004

Salinity is one of the most brutal environmental factors limiting the productivity of crop plants because most of the crop plants are sensitive to salinity caused by high concentrations of salts in the soil, and the area of land affected by it is increasing day by day. There is a need to develop simple and low cost biological methods for salinity stress management, which can be used on short term basis. Salt-tolerant PGPRs have own mechanisms for osmotolerance and could provide a significant benefit to the plants grown in saline soils, in terms of osmotolerance, better growth, vigour and yield. PGPRs enhance plant growth by several different mechanisms such as symbiotic N₂ fixation, solubilisation of mineral phosphate and other essential nutrients, production of plant hormones and other. Bacterial production of 1-aminocyclopropane-1- carboxylate deaminase, induced systemic resistance, ISR and control of phytopathogenic microorganisms in the rhizosphere are also modes of support to the plant. PGPRs mitigate salt stress in crops by enhancing osmolyte accumulation in plants, increasing K⁺ concentration and maintaining a high K⁺ /Na⁺ ratio and scavenging ROS generated by plants with bacterial antioxidant enzymes, etc. Understanding the interaction between consortium of microbial inoculants and plant systems will pave way to harness more benefits from microbial inoculants for improving plant growth and enhancing tolerance to stress.

ENVIRONMENT EFFECT OF AGRICULTURE THE NEED FOR FUTURE OF IPM

GAJENDRASINGH

Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P.) -250 110, India

Although IPM has been in participate in principle as the attractive option for the protection of agricultural crops from the ravages of insect and non insect- pests, yet implementation at the farmer's level has been rather limited. Some of the important constraints to wider adoption of IPM and suggested measures to overcome them are given below. Sustainability it is now increasingly that modern agriculture cannot sustain the present productivity levels with can only be by use of holistic pest management programmes. Economics if the cost of pesticide use are taken into account, IPM appears to be a more attractive alternative with lower economic costs. Health production, storage, transport, distribution and application of pesticides involves greater health hazards than the safer inputs and environment used in IPM. This endangers the safety of the entire population. Environment quality the ipm programmes, do not endangers non-target organisms do they pollute the soil, water and air. Social and political stability the pesticides used by the obtained from the corporate

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

house and even from other countries. The inputs in IPM are usually on local resources and outside dependence is minimized. This helps in maintaining social and political stability. Local knowledge IPM builds upon indigenous technological knowledge and seeks to build on farmers locally available.

STUDIES ON DEVELOPMENT FROM SQUASH (*CARRICA CARENDAS* L.), GINGER (*ZINGIBER OFFICINALIS* ROSC) AND ALOE VERA (*ALOE BARBADENSIS* MILLER.) BLENDS

GAMBHIR SINGH, RAVISHANKER SINGH AND ANUJ KUMAR

Department of Horticulture, N.D. University of Agriculture and Technology, Kumarganj, Faizabad, -224229, U.P., India

Karonda juice (*Carisa carandas* L.), Ginger juice (*Zingiber officinale* Rosc.) and aloe vera (*Aloe barbadensis* Miller.) gel have nutritional, medicinal and therapeutic values. The karonda juice, Ginger juice and aloe vera gel are used to prepare palatable squash 25 per cent of blend consisting 50 per cent karonda juice, 25 percent ginger juice and 25 per cent aloe vera gel, 50 per cent sugar, 1.25 per cent acidity. Observation on changes during storage revealed that TSS, acidity, reducing sugars, total sugars contents and browning increased whereas, Vitamin-C, non-reducing sugar and organoleptic score decreased continuously with storage period. The syrup prepared from blend of karonda and aloe vera gel could be stored was up to five months under ambient conditions with acceptable quality. Fruits are sour and astringent in taste and are rich source of iron (39.1mg/100g). The karonda fruit also contains good amount of vitamin C (1.6-17.9 mg/ 100g), calcium (21mg/100g), phosphorus (38mg/100g) and protein (1.1-2.25%). Karonda is very useful in curing anemia. The karonda fruits have antiscorbutic properties also. Raw or mature fruits contain high amount of pectin and they are most suitable for pickle making which is liked very much all over the India. These can also be used for making jelly and candy. The wine prepared from ripe fruits contains about 14.5 to 15% alcohol and very much liked by wine fanciers. Ripe fruits can be processed into a squash, syrup or RTS bottled drink.

GENETIC DIVERSITY AND PLANT GENETIC RESOURCES

GANESH KUMARKOLI, SNEHA GUPTA, VASANTHY. AND B. SINHA

Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi 221005, U.P., India

Biodiversity refers to variation within the living world, while genetic diversity represents the heritable variation within and between populations of organisms, and in the context of this paper, among plant species. This pool of genetic variation within an inter-mating population is the basis for selection as well as for plant improvement. Thus, conservation of this plant genetic diversity is essential for present and future human well-being. During recent years, there has been increasing awareness of the importance of adopting a holistic view of biodiversity, including agricultural biodiversity, conservation for sustainable utilization and development. These principles have been enshrined in the Convention on Biological Diversity and the Global Plan of Action of the Food and Agriculture Organization of the United Nations. The emphasis is now to understand the distribution and extent of genetic diversity available to humans in plant species, so that the genetic diversity can be safely conserved and efficiently used. It is generally recognized that plant genetic diversity changes in time and space. The extent and distribution of genetic diversity in a plant species depends on its evolution and breeding system, ecological and geographical factors, past bottlenecks, and often by many human factors. Much of the large amount of diversity of a species may be found within individual populations, or partitioned among a number of different populations.

A better understanding of genetic diversity and its distribution is essential for its conservation and use. It will help us in determining what to conserve as well as where to conserve, and will improve our understanding of the taxonomy and origin and evolution of plant species of interest. Knowledge of both these topics is essential for collecting and use of any plant species and its wild relatives. In order to manage conserved germplasm better, there is also a need to understand the genetic diversity that is present in collections. This will help us to rationalize germplasm and develop and adopt better protocols for regeneration of germplasm seed. Through improved characterization and development of core collections based on genetic diversity information, it will be possible to exploit the available resources in more valuable ways.

KEY ROLES OF BIOFERTILIZERS IN SOIL FERTILITY AND PRODUCTIVITY: A BRIEF REVIEW

GANPAT LOUHAR^{1*} AND DIVYA GAUR²

^{1*}Division of Soil Science and Agricultural Chemistry, IARI, New Delhi, 110012, ²Department of Soil Science, CCSHAU, Hisar, 125004, Haryana

Current soil management practices are mainly depends on chemical fertilizers, which reduced the human health and environment. Biofertilizers has become prime importance in agriculture for food security and sustainable crop production. Biofertilizers or microbial

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

inoculants defined as preparations containing live or latent cells of efficient strains of nitrogen fixing, phosphate solubilising or cellulolytic and lignolytic microorganisms used to increasing the availability of essential macro and micronutrients which can be easily assimilated by plants. Different types of microbial inoculants such as *Rhizobium*, *Azospirillum*, *Azotobacter*, *Azolla* and *BGA* (blue green algae) can add 30-180 kg N/ha year thereby increases 15-25 % of total crop yield. They help in mineral nutrition, water uptake, root development, vegetative growth and atmospheric nitrogen fixation. Some species of biofertilizers such as *Rhizobium*, *BGA*, and *Azotobacter* stimulate the growth promoting substance such as vitamin-B complex, Indole acetic acid (IAA) and gibberellic acid. Phosphate mobilizer or phosphorus solubilizer converts insoluble form of phosphate to soluble form. Mycorrhiza (VAM fungi) helps in uptake of nutrients e.g. P, Zn and S, liberate growth promoting substances to maintain soil fertility and bio-control of soil borne plant pathogens and diseases. They are cost effective, pollution free, eco friendly and renewable energy sources. They improve physical properties of soil, soil tilth; soil health and quality thus, improve soil fertility and soil productivity.

Keywords: biofertilizers, soil fertility, soil productivity, food security.

RECLAMATION OF SALT AFFECTED SOILS

GARIMADHIYA¹ ISHA²

Department of Soil Science, CCSHAU, Hisar, Department of Agronomy, CCSHAU, Hisar

Soil salinity, a worst hindrance to crop growth and the most common problem of today's era. Soils which possess excessive soluble salts mainly chlorides and sulphates of sodium, calcium and magnesium are termed as saline soils. Soil salinization is mainly due to the use of saline water for irrigation, seepage from the canals, high evapotranspiration rate and poor drainage (due to hard pan). It can easily be recognized by a layer of white crust on the soil surface. Mainly it is found in arid and semi-arid regions. Sodium present in the soil has a dispersing action on the soil particles thus affecting plant growth. The factors contributing to soil salinity are lack of proper drainage facilities, applying heavy dose of fertilizers and even the parent material is also a major contributing factor for that. Soil salinity affects the growth at critical stage and has a long-term effect on soil productivity and in turn crop growth is also affected. Reclamation of these soils is quite essential to achieve better plant stand as well as in improving the soil condition. And this objective can be achieved by either leaching with good quality irrigation water or proper drainage facilities. Reclamation of these soils involve removing excess soluble salts from the root zone such that there is no injury to crop growth due to the osmotic pressure of soil solution. Also, green manuring, use of crop residues, afforestation, use of soil amendments (gypsum or sulphur compounds) and growing of salt tolerant crops (barley, Sugarbeet, cotton, etc.) can also play a key role in this regard.

ABSTRACT FOR THEME 1: RECENT TRENDS IN AGRICULTURAL SCIENCES AND TECHNOLOGY

HYDROGEL: A BOON FOR WATER CONSERVATION

Garima Singh, Archana Kumari, Durgesh Singh, Asheesh Chaurasiya, Department of Agronomy, BAU, Sabour, Bhagalpur- 813210

Labour and water scarcity in India are driving researchers and farmers to find alternative management strategies that will increase water productivity and reduce labour requirement while maintaining or increasing land and water productivity because irrigated agriculture is a major sector affecting water use. Excessive demand coupled with mismanaged water resources and climate change have led to a sad state of affairs. The country's agriculture accounts for approximately 90% of the water consumption and thus, cripples with water stress as a result of unpredictable monsoon and climate change. To put it simply, there's too much demand and not enough supply. So, maximization of water productivity is one of the most important policy in developing countries like India to produce more crop per drop. There is a practically convenient and economically feasible technology i.e. hydrogels, which can help in water threatened agriculture in arid and semi-arid regions of India. It can be used as a technology in water conservation as mitigate water stress, increase water-holding and water use (up to 85% for sand), improve soil permeability, reduce need for irrigation, reduce soil erosion and leaching, ultimately improves plant growth and yield. Hydrogel agriculture technology uses insoluble gel-forming polymers applied directly in soil at the time of sowing of crops in fields or in growth medium for nursery plants. This technology is effective for all crops in relation to soil type and climate of India reporting improvement in growth and yield attributing characters and yield of different field, ornamental and vegetable crops. Agricultural hydrogels are eco-friendly (degrade without leaving toxic residue in plant or soil) and with an addition to water saving they also aid in improving the physio-chemical and biological properties of soil. Hence application of hydrogel may be a fruitful option for increasing agricultural production with sustainability in water-stressed environment. In adopting this technology ensures increased crop yield, high water use efficiency, reduced water and energy consumption.

RESOURCES OPTIMIZATION FOR RICE CROP USING CERES-RICE MODEL IN TARAI REGION OF UTTARAKHAND**GAURAV CHATURVEDI, A.S. NAIN, SHIVANI KOTHIYAL AND SOUPAYAN SAHA***Department of Agricultural Meteorology, G.B. Pant University of Agriculture and Technology, Pantnagar-263145*

Crop simulation modelling is widely accepted as a useful tool for research and management purposes in agriculture. In the study, CERES-Rice model was used to optimize the resources for the rice crop in the field trial experiment that was conducted in the year 2016. The rice varieties that were grown were *HKR-47* and *Pant Basmati-1*. The experiment was laid in Randomized block design (RBD) in three different treatments and three replications. Crop was found to yield more when the crop was transplanted on 25th June, than the crop that was transplanted on 5th July and 15th July. The model prediction was good and there wasn't much difference between the observed and simulated values. Adaptation to climate change consists of initiatives and measures to reduce vulnerability of natural and human systems against actual or expected climate change effects. To combat the effects of climate change on the crop yield, several techniques and measures are adopted and taken into practice. Adaptation techniques using crop simulation models have proved to be a boon for agriculture sector. Climate change scenario i.e. rise in temperature by 1.7 °C during the year 2050 was taken as a strategic intervention to minimize adverse effect of climate change. Changes were made in the transplanting dates, fertilizer application dates and the fertilizer doses which gave significant differences in the output.

Keywords: Adaptation, vulnerability, Climate Change.

EFFECT OF WEANING AGE AND MILK FEEDING LEVEL ON PRE- AND POST-WEANING GROWTH PERFORMANCE OF GANGATIRI CALVES**GAURAV JAIN * AND AJIT SINGH***Department of Animal Husbandry and Dairying, SHUATS Allahabad, Government Veterinary Hospital Chilla Allahabad.*

The objective of the present study was to evaluate pre- and post-weaning growth of Gangatiri calves weaned either at 8 or 12 weeks and offered milk at either 10% or 15% of bodyweight (BW) from birth to weaning. Colostrum fed Gangatiri calves (n = 48) were randomly allocated to four treatments of 12 calves each. Calves were offered milk either at 10% (low-milk) or 15% (high-milk) of BW in two weaning programs (early or late). Early weaned calves were offered milk until Day 35, adjusted weekly for liveweight and then reduced by one-third in each subsequent week until weaned at Day 56 (early weaned). Late-weaned calves were offered milk until Day 63 and were weaned at Day 84 (late-weaned) by reducing milk offered by one-third in each subsequent week. Calves were offered a concentrate ration (21% crude protein and 2.93 metabolisable energy, Mcal/kg) from Day 28 to Day 112. Final BW at 16 weeks was highest (74.6 ± 1.8 kg; $P < 0.01$) in high milk-fed late-weaned calves and lowest in low milk-fed early weaned calves (58.2 ± 1.8 kg). High-milk early weaned and low milk late-weaned calves had comparable final BW (68.7 ± 1.8 vs 72.0 ± 1.8 kg), although lower than that of high-milk late-weaned calves. Thus, offering milk to Gangatiri calves at 15% of BW and weaning at 8 weeks saves milk and labour required for additional days to feed these calves.

Keywords: Gangatiri, calves, weaning age, growth performance.

“EVALUATION OF LINSEED (*LINUM USITATISSIMUM* L.) GERMPLASM FOR IDENTIFICATION OF RESISTANT GENOTYPES AGAINST ALTERNARIA BLIGHT”**GAURAV KUMAR YADAV¹, DHARMENDRA KUMAR²***Department of Plant Pathology, Sardar Vallabhbhai Patel University of Agri. & Tech. Meerut. (U. P.) 250110*

Alternaria blight of is an important disease of Linseed (*Linum usitatissimum* L.) that hampers its productivity and oil content. Studies on symptoms appearance of Alternaria blight of linseed were first appeared on lower leaves as black point that gradually increased in size to become circular to oval or irregular in shape. During severe infections, spots coalesced and covered the large area of the leaves. Microscopic examination of pathogens in diseased tissue revealed that *Alternaria linicola* Groves & Skolko and *Alternaria lini* Dey were two fungi associated with the spots on leaves and capsules. Studies of relative dominance of pathogens associated with the diseased tissue revealed the dominance of *Alternaria linicola* (95.86-98.63%) in comparison to *A. lini* (1.31-4.14%) during different growth period of linseed crop. During study of variability of pathogen, five isolates of *A. linicola* were isolated and variability in growth and pathogenicity were observed. Isolate of Kanpur was found more virulent in comparison to other isolates. Sixty three genotypes were evaluated against this disease under artificial epiphytotic condition to know the level of resistance and susceptibility in different genotypes under artificial inoculated conditions. Out of Sixty three genotypes screened, 2 genotypes namely LCK-152, LCK-7002, rated as resistant, under both the years. While 4 genotypes namely- BUAPUR LOCAL, CR-M-6X22-9, EC-9832, OLC-48 in 2015-16 and 3 genotypes in 2016-17 rated under highly susceptible lines against this disease.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

ECONOMICS OF WHEAT PRODUCTION IN SELECTED DISTRICTS OF WESTERN UTTAR PRADESH

GAURAV TOMER, ROHIT CHAUDHARY, AOBAKWE GABABOLOKWE, PV NAGA SINDHUJA, VIKAS KUMAR SHARMA

Department of Agricultural Economics, SVP University of Agriculture & Technology Meerut-250110

The present study has been made to work out the cost of cultivation, profitability and production of wheat (grain + straw) in Baghpat, Meerut, Muzaffarnagar and Shamli districts of West Uttar Pradesh. The primary data were collected from 39 sample respondents (farmer and < 2 hectare.) through pre-tested interview schedule. The total cost of cultivation was found to be (80730.70 Rs./hectare). The gross returns received from wheat cultivation was to be ` 97580.16 Rs./hectare on overall farms. Total area of 39 wheat farmers were 24.72 hectare and average area was 0.633846154 hectare. The average net profit, average land preparation cost, average manuring cost, average seed & sowing cost, average fertilizer application cost, average irrigation cost, average weeding & inter-culture operation cost, average plant protection cost, average harvesting cost, average threshing cost, average variable cost, average fixed cost, average total cost, average cost of by-product, average grain cost, average yield cost (grain+straw), average gross return regarding average area *i.e.* (0.633846154 hectare) were found to be `7330.72, `5926.92, `689.10, `2683.51, `272.51, `792.76, `983.82, `4.35, `6801.82, `733.94, `5029.82, `18514.97, `3093.92, `63.91, `27.22, `54.02, and `61850.81 per hectare, respectively on overall farms. The wheat cultivators reported that potential yield could not be achieved due to various production constraints *viz.* lack of technical knowledge regarding soil testing facilities, lack of knowledge of plant protection measures, lack of knowledge of recommended package of practices, irregularity of electricity supply, lack of capital, lack of proper training, disease problems, unavailability of high yielding variety seed and only 3 farmers out of 39 has been applying plant protection chemicals at the time of study. During study the cost of production was founded Rs. 1580.82.

Keywords: Total net profit, cost of cultivation, cost of production.

SOIL HEALTH, LAND RESOURCES AND LAND USE PLANNING AND MANAGEMENT

GAVASKAR AND RADHAKISHAN YADAV

Department of soil science and agri. Chem., Naini Agriculture Institute, Sam Higginbottom University of Agriculture, Technology and Sciences, Allahabad, 211007 U.P., India.

Soil health, is also referred to as soil quality, is defined as the continued capacity of soil to function as a vital living ecosystem that sustain plants, animals, and humans. Soil health is the condition of the soil in a defined space and at a defined scale relative to a set of benchmarks that encompass healthy functioning. It would not be appropriate to refer to soil health for soil-roadbed preparation, as in the analogy of soil quality in a functional class. The definition of soil health may vary between users of the term as alternative users may place differing priorities upon the multiple functions of a soil. Therefore, the term soil health can only be understood within the context of the user of the term, and their aspiration of a soil, as well as by the boundary definition of the soil at issue. Land resources mean the resources available from the land, thus the agricultural land which contain natural fertilizer for growth of the products sown; the underground water, the various minerals like coal, bauxite, gold and other raw materials. Land use planning technique to improve the quality of life in urban areas. This widely adopted technique is one of the most successful methods followed today. According to this various socio-economic activities are allocated space in a particular area, or in other words, areas are assigned based on specific activities based on various parameters which will help in increasing overall efficiency of the urban area. Land-use planning and management is an effective means to ensure that the activities nearby airports are compatible with aviation. Its main goal is to minimize the population affected by aircraft noise by introducing land-use zoning around airports.

Keywords :- Soil health, Land resources, Land use planning, Land management etc.

CROP QUANT: A NEW FRONTIER AUTOMATED PORTFOLIO FOR PRECISION PHENOTYPING, CROP MONITORING AND DIGITAL AGRICULTURE

GAYATRI KUMAWAT*, MANISH KUMAR CHOUDHARY, MUNNESH KUMAR, ASHOK SINGAMSETTI, AND J.P. SHAHI

Department Of Genetics and Plant Breeding, Institute Of Agricultural Sciences, Banaras Hindu University, Varanasi-221005, U.P.

Crop Quant is a new an automated technology utilised to throughput phenotyping for crop monitoring and digital and precision agriculture. This technology is utilised for measuring of crop breeding and agronomic practices. High-frequency and high-precision

phenotypic analysis can enable both accurate delineation of the genotype-to-phenotype pathway and the identification of genetic variation influencing environmental adaptation and yield potential. An automated and scalable field phenotyping platform called Crop Quant, designed for easy and cost effective deployment in different environments and preventing crop losses and contributing to food security. To manage in field experiments and crop-climate data collection developed a web-based control system called CropMonitor to provide a unified graphical user interface (GUI) to enable real time interactions between users and their experiments. A high-throughput trait analysis pipeline for phenotypic analyses established so that lightweight machine-learning modelling can be executed on Crop Quant workstations to study the dynamic interactions between genotypes (G), phenotypes (P), and environmental factors (E). These technologies have used since 2015 and reported results generated in 2015 and 2016 field experiments, including developmental profiles of five wheat genotypes, performance-related traits analyses, and new biological insights emerged from the application of the Crop Quant platform.

XOPR T3SS EFFECTOR OF *XANTHOMONAS ORYZAE* PV. *ORYZAE* PLAYS A CRUCIAL ROLE IN SUPPRESSION OF CELL DEATH MEDIATED RICE IMMUNE RESPONSE DURING BACTERIAL BLIGHT DEVELOPMENT

GEETA VERMA¹, KALYAN K MONDAL^{*1} AND MANJU SHARMA²

Division of Plant Pathology, ICAR-Indian Agricultural Research Institute, Pusa Campus, New Delhi, India, Amity Institute of Biotechnology, Amity University, Manesar Gurgaon, Haryana

Bacterial leaf blight caused by *Xanthomonas oryzae* pv. *oryzae* (Xoo) is a major biotic threat to basmati rice production in India. The bacteria suppress the rice innate immune responses by secreting effector proteins directly into the rice cells through type III secretory pathway. XopR one of the core effectors in Indian Xoo strain (race 4), was studied with particular reference to its participation as suppressor of plant defense responses including plant cell death (PCD). We constructed a null mutant for *xopR* gene in Xoo strain using a double crossing over based homologous recombination strategy. We experimentally confirmed that PCD in rice suppressed by the XopR. We further confirmed that PCD induction was compromised when XopR was transiently expressed in tobacco leaves, experimental host. This clearly suggests that XopR acts as suppressor of the PCD mediated defense response of rice events during infection. This apparently helps Xoo to get invaded in plant tissues for its sufficient multiplication. Altogether our study leads to the understanding that XopR T3SS-effector is essential for Xoo to suppress PCD and thereby it supports the *in planta* colonization of Xoo during blight pathogenesis.

Key words: *Xanthomonas oryzae*, T3SS, Phylogenetic analysis, PCD, EYFP.

COMPARATIVE ANALYSIS OF CARBOHYDRATES IN *ACACIA NILOTICA* SEED AND SEED PARTS

GEETENDRA KUMAR¹, N.K. SINGH² AND MANJOOSHA SRIVASTAVA³

^{1,3}Phytochemistry Division, CSIR-National Botanical Research Institute, Lucknow-226001, ²Department of Chemistry, University of Lucknow, Lucknow-226007

Objective: Identification and quantification of carbohydrates for part specific comparative study in *Acacia nilotica* seeds for nutritional and medicinal aspects. **Hypothesis:** *Acacia nilotica* indigenously known as 'Babool' and belong to family Leguminosae. *A. nilotica* has many traditional and ethanobotanical uses. All the plant parts of *A. nilotica* are important, but seeds are rich in phytochemicals viz. protein, sugar, starch, fatty acid, oil, alkaloids, glycosides, steroids, tannins, phenolics, flavanoid and cyclitols with high nutritional value and therapeutic effects viz. anti-microbial, antifungal, anti-pyretic, analgesic, anti-inflammatory, anti-diarrhoea, anti-asthmatic, cytotoxic and anti-diabetic. Carbohydrate is an important group of phytochemical with such nutritional and medicinal properties. Thus, *A. nilotica* seeds and their parts evaluated for carbohydrates to compare the part specific potential for safer utilization to mankind. **Method:** *A. nilotica* seeds along with cotyledon and endosperm were separated mechanically and powdered to 40 mesh. Powdered materials were then extracted in differential solvents viz. hexane, chloroform, acetone, ethanol and water. These extracts were used for qualitative study of carbohydrates. The quantitative estimations viz. total carbohydrate, sugar and starch were carried out in powdered materials according to the standard methods. **Results:** Ethanol and water extracts of seed, cotyledon and endosperm showed the presence of carbohydrates. Quantitative estimation revealed that total carbohydrate and total sugar were high in cotyledon i.e. 17.83% and 4.73% than seed and endosperm respectively whereas total starch was less in cotyledon than seed and endosperm i.e. 2.3%. **Implication:** Study revealed that cotyledon has rich nutritional and medicinal carbohydrates than the seed and endosperm. Thus, it may be specifically and better utilized for carbohydrate rich supplements and for useful bioactive extracts as natural products for sustainable health benefits.

Key words: *Acacia nilotica*, Carbohydrate, Medicinal, Nutritional, Health.

EFFECT OF DIFFERENT PREHARVEST APPLICATIONS ON PHYSIOLOGICAL AND SENSORY QUALITY OF NECTARINE CVS. SNOW QUEEN AFTER HARVEST**GHAN SHYAMABROL^{1*}, KAMAL SINGH THAKUR² AND NARAYAN SINGH THAKUR²**¹College of Horticulture and Forestry, Rani Lakshmi Bai Central Agricultural University, Jhansi-284003 (INDIA), ²Department of Food Science and Technology, Dr YS Parmar University of Horticulture and Forestry, Nauni Solan-173230 (INDIA)

The present study was conducted to see the effect of preharvest application of growth regulators, nutrients and fungicides on physiological and sensory quality of nectarine fruit. All the preharvest treatments showed a beneficial effect on different physiological and sensory parameter of fruits in comparison to control. Among the preharvest treatments, calcium chloride @ 1.5 per cent, Neemazal @ 0.45 per cent, salicylic acid @ 3000 ppm and CPPU @ 15 ppm proved to be most effective in maintaining fruit quality and minimizing deterioration during 28 days storage at 3 ± 1 °C. These treatments were also effective in reducing the respiration rate and enzymatic activities, thereby reducing the overall ripening process and prolonging storage life. Effect of salicylic acid is to be reported first time on nectarine fruits in the study.

Keywords: Nectarine, Snow Queen, sensory parameters, salicylic acid, CPPU, CaCl₂ and neemazal etc.

BIOFORTIFICATION OF WHEAT OR RICE, EFFECT OF WITH FYM AND WITHOUT FYM LEVEL IN RABI SEASON**¹GIRISH GOYAL, ² R. K. DOHAREY, ³NIDHEE SACHAN AND ⁴HEMANT KUMAR GANGWAR**^{1,4}Department of Agronomy, ³Department of Food Science and Nutrition, ²Department of Agriculture Extension, ¹C. S. Azad University of agriculture & Technology, Kanpur, ³Jiwaji University, Gwalior, ^{2,4}NDUA & TKumarganj, Faizabad

Biofortification of wheat and other cereal crops is being urgently addressed and highly prioritized as a research topic fortification is adding vitamins and minerals to foods to prevent nutritional deficiencies. The nutrients regularly used in grain fortification and improve productivity and cognitive development. As wheat is main source of protein and dietary energy for human beings, its potential to support reducing malnutrition related to Fe can be increased through producing genetically modified wheat varieties with high concentration of Fe. Even though during wheat is commonly fortified promising and more long term solution is biofortification of wheat which bases on the production of new wheat varieties with characteristically higher concentration of iron. Till now May researches, which focused on increasing Fe in wheat aimed at producing natural varieties in progenitor or related species. Biofortification of rice with micronutrient is the only tool to reduce micronutrient malnutrition of staple foods whose edible portions are denser in bio available minerals and vitamins. Inclusion of organic amendments (FYM) in fertilizer schedule was found promising in improving the Zn and Fe content of rice. FYM is one of the components of INM as it is a very food organic source of nutrients. It is a cheap and easily available source of organic nutrients for farmers. Integrating FYM with inorganic fertilizer, scientists are getting very good response of the crop. FYM can supply all the nutrients required by the plant, however, with low quantity. It is always advised to apply FYM to the soil along with chemical fertilizer so that the farmers can obtain very good crop yield.

PRESENTLY WHEAT CROP IS IN THE CROWN ROOT INITIATION (CRI) STAGE OR ECONOMIC IMPORTANT AND CLIMATIC REQUIREMENTS**¹GIRISH GOYAL, ² R. K. DOHAREY, ³PRADIP KUMAR SAINI AND ⁴NIDHEE SACHAN**¹Department of Agronomy, ²Department of Agriculture Extension, ³Department of Crop Physiology, ⁴Department of Food Science and Nutrition, ¹C. S. Azad University of agriculture & Technology, Kanpur, ^{2,3}NDUA & TKumarganj, Faizabad, ⁴Jiwaji University, Gwalior

Wheat is a grass widely cultivated for its seed, a cereal grain which is a worldwide staple food the presently wheat crop is in the Crown Root Initiation (CRI) stage in the Northern States of India. Current cool waves in the key producing states are congenial for the wheat crop growth, according to the Agriculture Expert. A turning point came in the history of wheat in 1965 with introduction of dwarf, photo insensitive, high yielding Mexican wheat breeding materials developed by " N.E. Borlaug". In 1970, triple dwarf varieties were released in India. In India, Wheat is second important staple food crop after rice. Wheat grain flour is used in form of chapatti, pure, bread, cake, sweetmeats, halwa etc. It provides 20 per cent of total calories for human race. Wheat grain contains 12.2 per cent protein, which is more than other cereals. Wheat provides characteristic substance "Gluten" which is very essential for bakers. In bakery, gluten provides the structural framework for the familiar spongy, cellular texture of bread and other bakery products. Wheat straw is also a good source of feed for a large population of cattle in our country. Wheat straw is also a good source of bedding material for livestock. Wheat crop has wide adaptability. Rainfall is one of the most important factors, especially when vegetables are grown under dry land conditions. It can be grown not only in the tropical and sub-tropical zone but also in the temperate zone. Dry and cool weather is most suitable for this crop. Adequate soil moisture is necessary for good crop establishment, good yields and good quality. This moisture may be obtained from rainfall or irrigation. The optimum temperature required for ideal germination of the wheat crop ranges from 20 to 25 °C. Rains received

immediately after sowing, hamper germination and encourage seedling blight, while high humidity and low temperature is conducive for rust attack.

PREDICTION OF HETEROSIS BASED ON TRANSCRIPTOME

GIRISH TANTUWAY AND ADITI ELIZA TIRKEY

Research Scholar, Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005

Transcriptome is a collection of whole mRNA providing information about the expressed genes in cell at particular time. Using transcriptome analysis, we can analyse the genes expressed in the parents and their hybrids, and determine the correlation between them. There are several techniques for analysing the transcriptome like cDNA library sequencing, microarray hybridisation and RNA sequencing. Among these, recently developed RNA sequencing technique, is the most popular method on account of several comparative advantages over other methods like high sensitivity and ability to detect splicing isoforms. Transcriptome is precursor for the proteome as the proteins are formed from the mRNAs produced in the cell. Analysis of relative mRNA expression levels is very complicated and difficult because of the fact that small changes in mRNA leads to large changes in the total amount of the corresponding protein present in the cell. The transcriptome profiles and DEGs in the F_2 s have been found related to phenotype bias to the positive GCA effect of parent. The transcriptome bias was also demonstrated by analyzing the genes that controlled the specific phenotypes of plant height and flowering, and H3K36me3 modification on global modification or specific signalling pathways. The transcriptome-based prediction of heterosis and hybrid performance can be useful approach in the future because it directly analyses the expression profiles of the genes. This approach utilises the expressed part of the genome which gives direct relationship with the phenotype. The advents in RNA sequencing technology (RNA-Seq) provide an opportunity to conduct in-depth transcript profiling for heterosis studies. Presently, the technology is in infancy but has high prospect of multiple applications in plant breeding.

Key words: Transcriptome, RNA sequencing, DEGs

CROP RESIDUE MANAGEMENT FOR IMPROVING SOIL FERTILITY AND ENHANCING CROP PRODUCTION

GIRJASHANKER TEWARI¹, NAVNEET PAREEK² AND POONAM GAUTAM³

Department of Soil Science, GBPUAT, Pantnagar- Uttarakhand, Department of Soil Science, GBPUAT, Pantnagar- Uttarakhand, Junior Research Officer, Department of Soil Science, GBPUAT, Pantnagar- Uttarakhand

The cultural practices prevailing in the present agricultural scenario pose a very deleterious effect on soil fertility. The land has been used extensively over and over again; use of chemical fertilizers has been increased that has led to the deterioration of the land. The inherent capacity of the soil i.e., soil fertility, is now decreasing day-by-day. Soil fertility can be defined as, “the ability of soil to sustain crop growth in the long-term”. Soil fertility can be determined by the physical, chemical and biological processes that are interlinked to its soil organic matter content and its quality. Decrease in soil fertility is a major constraint towards low productivity. In recent years, concerns towards healthy food production and environmental quality have been increased. The increased emphasis on sustaining the fertility of soils has raised interest in maintenance and improvement of soil organic matter through appropriate land use and management practices. Crop residues are one of the important source of organic matter that are the left-over of the main produce and upon returning it to the soil for nutrient cycling helps to improve soil physical, chemical and biological properties. Its effective management in the field conserves the soil and its resources causing least damage to the environment.

SOIL HEALTH MANAGEMENT FOR SUSTAINABLE AGRICULTURE

GOVIND KUMAR YADAV*, D.D. SAWALE, A.D. JAGDHANI**, B.D. TAMBOLI***, G.D. PATIL*****

Division of Soil Science & Agricultural Chemistry, College of Agriculture, Pune-5, MPKV, Rahuri-413722

The concept of soil health or soil quality emerged in the 1990's as the pressure on the land increased. Soil quality as “the capacity of soil to function, within land use and ecosystem boundaries, to sustain biological productivity, maintain environmental health, and promote plant, animal and human health. This definition speaks to the importance of managing soils so they are sustainable for future generations. By using management practices that improve soil health and increase productivity and profitability immediately and into the future, Soil disturbance can be the result of physical, chemical or biological activities. Physical soil disturbance, such as tillage, results in bare and/or compacted soil that is destructive and disruptive to soil microbes, and it creates a hostile environment for them to live. Misapplication of farm inputs can disrupt the symbiotic relationships between fungi, other microorganisms, and plant roots. Overgrazing, a form of biological disturbance, reduces root mass, increases runoff, and increases soil temperature. All forms of soil disturbance diminish habitat for soil microbes and result in a diminished soil food web, increase diversify soil biota with plant diversity, increase the use of organic

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

manures, organic manures often improve the productivity of soils and the nutritional value of crop grown, minimum use of fertilizers and pesticides, keep a living root growing throughout the year, keep the soil covered as much as possible Soil cover conserves moisture, reduces temperature, intercepts raindrops, suppresses weed growth, and provides habitat for members of the soil food web that spend at least some of their time above ground. This is true regardless of land use. Keeping the soil covered while allowing crop residues to decompose can be a bit of a balancing act.

Keywords: Soil quality, Productivity, Soil temperature, Raindrops

EFFECT OF FOLIAR APPLICATION OF IRON (FeSO_4) AND ZINC (ZnSO_4) ON PLANT GROWTH, FLOWERING AND CORM PRODUCTION OF GLADIOLUS C.V. PUSA VIDUSHI.

GOVIND KUMAR^{*}, V.N. MISHRA^{**}, B. K. CHATURVEDI^{**} AND ANKIT CHAUHAN^{*}

The gladiolus (*Gladiolus grandiflorus*) belongs to the family Iridaceae and sub-family Exioideae. Which is a bulbous cut flower plant of winter season. It is native to South Africa. It being a potential cut flower grown globally for its attractive spike. Its cut flowers are increasing day by day owing to long self life of its beautiful flowers use to on tables in vases and in the decoration of house and also used in bouquet to offering. Keeping these facts in mind the present study was undertaken at the department of horticulture Raja Balwant Singh college, Bichpuri, Agra. During 2013-14. The experimental variety Pusa Vidushi was planted at 30cm. (row to row) $\times$ 25cm (plant to plant) apart. The experiment was conducted under randomized block design having 9 treatment combinations including 3 concentrations of FeSO_4 i.e. (F_0 -0.0%, F_1 -0.2%, F_2 -0.4%) and 3 concentrations of ZnSO_4 viz. Z_0 =0.0%, Z_1 =0.2%, Z_2 =0.4% which were replicated thrice. On the basis of data recorded during experimentation, it was found that significant effect among treatment and maximum enhance in plant height (80.89cm), total no. of leaf per plant (10.92), maximum length of spike (37.78cm), weight of spike (39.73gm), no. of florets per spike (14.55), maximum vase life (16 days) and no. of corms (266667/ha.) were recorded with foliar spray of 0.4% FeSO_4 (F_2) and 0.4% ZnSO_4 (Z_2).

E-NAM :- A SUSTAINABLE AGRICULTURE MARKETING AND EXTENSION PLATFORM FOR DOUBLING FARMER'S INCOME

GOVIND PRASAD¹, R.S. SENGAR², MD. AFJALAHMAD³

1 & 2 Department of Agricultural Extension, IGKV, Raipur (CG), 3 Department of Plant Physiology, IGKV, Raipur (CG), Indira Gandhi Krishi Vishwavidyalaya, Raipur (C.G.)

Prosperity of Indian agriculture is possible through two ways: one by emphasizing production constraints which leads to greater agricultural productivity and the other by making agricultural produce accessible to the market where it can be sold off giving remunerative prices to farmers. The country has made significant progress in agriculture production, but agriculture marketing and extension is a challenging task which needs to be addressed immediately. e-NAM or national agriculture market is an online marketing and trading platform for purchase and sale of agriculture commodities by buyers, traders, exporters and ultimately benefiting the farming community. The e-NAM was launched on 14 April 2016 with an objective to centralise, streamline and strengthen agriculture marketing and extension sectors in India. It is a common online trading platform to all the stakeholders, the farmers registered in e-NAM gets fair price or high price for their produce on the other hand, the buyers or traders gets quality agriculture produce in bulk at a time therefore this process eliminates the brokers, agents or middlemen. It is considered to be a transformative step which can revolutionise the agri marketing and extension sector in Indian Agriculture sector. Thus linking all the progressive farmers across all the states and involving all the stakeholders can result in doubling the farmer's income and improving the livelihood of farming community.

Key Words: e NAM, Agri marketing, farmers

RESPONSE OF DIFFERENT MATURITY GENOTYPES OF MAIZE UNDER DIFFERENT DATES OF SOWING IN KHARIF SEASON IN HARYANA

GOVIND PRASAD^{*}, MEHAR CHAND, PAWAN KUMAR AND AJAY SINGH

^{*}Department of Agronomy, CCS Haryana Agricultural University, Hisar- 125 004

A field experiment was done during *kharif* season to evaluate the response of different maturity genotypes of maize under different dates of sowing in *kharif* season in Haryana. The experiment was laid out in split plot design with four date of sowing (15th June, 25th June, 5th July and 15th July) as main plot and five maize hybrids of different maturity group namely, HQPM-1 (late), HM-4 (medium), HM-5 (late), HM-6 (early) and HM-7 (extra early) in sub plot replicated thrice. The sowing of maize was done by hand dibbling with a spacing of 75 cm $\times$ 20 cm using a seed rate of 20 kg/ha. Ten days advance, normal and 10 days delay sowing being at par recorded significantly higher plant height, dry matter accumulation, crop growth rate (CGR), days to 50 % tasseling, 50 % silking and maturity and grain yield over

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

delayed sowings by 20 days from normal sowing. The effect of sowing date had no significant effect on plant population and relative growth rate (RGR). Among hybrids, HQPM-1 recorded highest plant height at harvest followed by HM-4, HM-7, HM-6 and lowest in HM-5. HM-5 recorded highest dry matter followed by HQPM-1, HM-4, HM-6 and lowest in case of HM-7. HM-5 recorded higher CGR from 60 DAS to maturity than all other hybrids. Higher RGR was recorded under HM-4 than all other hybrids. HM-7 and HM-6 took lower number of days to attain 50 % tasseling, 50 % silking and maturity stage. HQPM-1 and HM-5 being at par took higher number of days to 50 % tasseling, 50 % silking and maturity as compared to HM-4. HM-5 recorded highest grain yield (76.3 q/ha). HM-5 produced 17.5, 37.8, 44.9 and 50.1 % higher grain yield over HQPM-1, HM-4, HM-6 and HM-7, respectively

Key words: Date of Sowing, Hybrids, *Zea mays*, Growth studies and yield

EFFECT OF FEEDING TURMERIC (*CURCUMA LONGA*) AND AMLA (*EMBLICA OFFICINALIS*) POWDER ON GROWTH PERFORMANCE OF BROILERS

GYAN CHANDRA*, S.H. MANE**

Department of Animal Husbandry & Dairy Science, College of Agriculture, Pune-5, MPKV, Rahuri - 41372

Feeding trial was conducted at poultry unit, Department of Animal Husbandry & Dairy Science, College of Agriculture, Pune, in study the effect of feeding Turmeric and Amla (powder) on growth performance of broilers to the different herbal feed supplement either alone or in combination on broiler diet. The treatment groups consisted of control (T0), 0.25% turmeric (T1), 0.5% turmeric (T2), 0.25% amla (T3), 0.5% turmeric (T4), 0.25% turmeric+amlam (T5) and 0.5% and turmeric+amlam (T6) were included in broiler diet. The feed supplement would give better performance. The results of included body weight, body weight gain, feed consumption, feed conversion ratio, cost of feed per kg, and mortality. In the experiment turmeric and amla (powder) were used at the recommended levels (0.25% and 0.5%) in different either alone or in combination in treatments. The results T5 (0.25%) and T6 (0.5%) indicated that turmeric in combination with amla (powder) gave the better growth performance and also economic returns higher T5 (Rs. 54.51/bird) and T6 (Rs. 54.74/bird) compared to control and other groups. The higher dressing percentage (72.20 %) and meat bone ratio (14.36%) were observed in T6 on per cent live weight basis.

Keywords : Broilers, growth performance, body weight, bone ratio

APPROACHES FOR GENETIC ENHANCEMENT OF CULTIVATED SUNFLOWER (*HELIANTHUS ANNUUS* L.) FOR DESIRABLE TRAITS

HARI PRAKASH MEENA,* SUJATHA Mulpuri, MANGESH Y. DUDHE AND A. VISHNUVARDHAN REDDY

ICAR-Indian Institute of Oilseeds Research, Rajendranagar, Hyderabad-500 030, India

Sunflower by virtue of its wide adaptability has established itself as a major oilseed crop in southern part of the country and has also made a dent in non-traditional areas of Northern India in spring season. Effective utilization of sunflower genetic resources resulted in release of 21 varieties/populations and 37 CMS based hybrids through AICRP in India. Despite these successes with the crop, the major problems threatening sunflower productivity in India are the stagnating and unstable yields and vulnerability to various biotic (sunflower necrosis disease (SND), leaf curl virus (SuLCV), *Alternaria* and powdery mildew) and abiotic (drought and salinity) stresses. Plant breeding efforts to develop varieties/hybrids with inbuilt tolerance to the major diseases are constrained by the narrow genetic base of the cultivated sunflower and low utilization of genetic resources. It is evident that identification of broad diversified parental lines and their utilization for maximization of heterosis is the need of the hour. Towards this goal attempts were made during the past decade to augment breeding lines (CMS, R lines and inbreds) from USDA, USA and also wild *Helianthus* species from USDA, USA and IFVCNS, Serbia. Screening of wild *Helianthus* species resulted in identification of both annual and perennial species confirming resistance to major biotic and abiotic stresses in India. Using conventional methods and techniques of crossing, backcrossing and selection, several prebred lines with altered plant architecture, high yield and oil content, maturity duration and inbuilt tolerance to major biotic stresses have been developed using wild sunflowers at IIOR. The paper deals with the efforts being made and approaches followed to broaden the genetic base of cultivated sunflower for various agronomically desirable traits using exotic germplasm and related wild diploid annuals and perennial species. Prebreeding ensures continuous supply of novel and diverse genetic variability derived from wild *Helianthus* species in readily usable form into the breeding pipelines to develop new climate-resilient cultivars with a broad genetic base.

Key words: Augmentation, genetic enhancement, wide hybridization, interspecific derivatives, wild sunflowers.

NUTRIENT MANAGEMENT IN PIGEONPEA BASED INTERCROPPING SYSTEM UNDER RAINFED CONDITION**NEERAJ KUMAR, ATIKAHMAD, RAJESH KUMAR, H. C. SINGH, AND S.F.A. ZAIDI***Department of Agronomy, N.D. University of Agriculture & Technology, Kumarganj, Faizabad 224 229 (U.P.), India*

Pigeonpea is one of the most important and popular pulse crop with Indian farmers especially in view of their sustainability under dry land conditions and their adoptability for pure as well as mixed/ intercropping system. Nutrient management is a key issue in obtaining potential yield of both crops in any intercropping system. Phosphorus is a major essential nutrient required by pulses. Integrated nutrient management mainly aims at the maintenance of soil fertility as a result of nutrients supply to an optimum level for sustaining the desired crop productivity through optimization of the benefits from all possible resources of plant nutrients in an integrated manner. Pigeonpea is a long duration, slow initial growth and wider spacing crop so it provides good scope for intercropping of short duration cereals, pulses and oilseeds. Nutrient management in intercropping system is entirely different from sole cropping, as the requirement of each component crop has to be taken care of. Intercropping of pulses with other crops increases nutrient status of soil and improve the soil health (Singh *et al.* 2012). A field experiment was conducted during *kharif* season of 2012-13 to 2014-15 at Agronomy Research farm of N. D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.). The soil of experimental field was silty loam in texture having 0.29 per cent organic carbon, 155 kg ha⁻¹ available N, 15 kg ha⁻¹ P₂O₅ and 240 kg ha⁻¹ K₂O with 7.76 soil pH. The experiment was laid out in the factorial randomized block design with 3 replications. The treatments were consisted of three intercropping systems (pigeonpea sole, pigeonpea + black gram and pigeonpea + maize). Seeds of pigeonpea and black were inoculated with *Rhizobium*, PSB and Nano biofertiliser (Harit vardan) as per treatment and FYM was also applied as per treatment before sowing. The crops (pigeonpea 'Narendra arhar-1', Black gram 'Narendra Urd-1, Maize 'MM 1107') were sown. Recommended dose of fertilizers for both pigeon pea and black gram was 20:40:0 kg NPK /ha, which was applied as basal at the time of sowing. However, in maize half dose of nitrogen (40 kg/ha) and full dose of P₂O₅ (40 kg/ha) and K₂O (30 kg/ha) were applied as basal and remaining half of N (40 kg/ha) was top dressed in two equal splits, one at knee height stage and another at tasseling stage of the crop under optimum moisture in soil. Fertilizers in intercropping treatments were given as per row arrangements. Recommended package and practices of crop production were followed. Pigeonpea-equivalent yield was calculated by converting the grain yield of black gram and maize into pigeonpea yield on the basis of existing market price of the crops. The higher grain yield of pigeonpea (15.82 q/ha) was recorded under pigeonpea + blackgram intercropping system which was significantly higher to pigeonpea sole (14.03 q/ha) and pigeonpea + maize (10.97 q/ha). Sizable reduction in pigeonpea yield under pigeonpea + maize intercropping system was due to more competition between maize and pigeonpea for space, nutrients, soil moisture and solar energy. Pulses crop seed inoculated with PSB + *Rhizobium* culture along with RDF and FYM increased the grain yield of pigeonpea, black gram and maize. Significantly higher pigeon pea equivalent yield (PEY) (23.47 q/ha) and Rain Water Use Efficiency (5.92 kg/ha/mm) was recorded under pigeonpea + black gram inter cropping system over pigeonpea sole and pigeonpea + maize. Inoculation of pigeonpea and blackgram seeds with PSB and *Rhizobium* culture significantly increased PEY (17.85 q/ha) and RWUE (4.44 kg/ha/mm) over RDF alone. Similarly addition of FYM @ 5 t/ha along with RDF + PSB + *Rhizobium* culture were also significantly increased the PEY (20.32q/ha) over rest of the nutrient management system while at par with addition of harit vardan biofertilizer (21.48 q/ha). Significantly higher values of available nitrogen, phosphorus and potassium were found under the pigeonpea + blackgram intercropping system compared to pigeonpea sole and pigeonpea + maize intercropping system. Under nutrient management system, pigeonpea and blackgram seed inoculation with PSB and *Rhizobium* culture was not significantly increased organic carbon, while, increased significantly N, P₂O₅ and K₂O in soil over RDF. Incorporation of FYM @ 5 t/ha significantly increased the availability of N and P₂O₅ in soil. Higher net return (Rs. 70170/ha) as well as B: C ratio (2.20) were fetched under pigeonpea + blackgram intercropping system than sole pigeonpea (Rs.58407/ha) and pigeonpea+ maize cropping system (Rs.47796/ ha) due to increase in pigeonpea yield and additional yield of blackgram, which resulted in higher pigeonpea equivalent yield (PEY). Maize crop adversely affected the yield of pigeonpea. Similarly highest net return (Rs. 62197/ha and B: C ratio (1.98) was found in N₄. Similar results have been reported by Tiwari *et al.* (2012).

EFFECT OF DIFFERENT LEVELS OF NITROGEN AND SILICA ON GROWTH AND YIELD OF RICE**H. D. RANE*, N. B. GOKHALE, M. C. KASTURE AND ANURADHA HARMALKAR***Department of Soil Science and Agril. Chemistry, College of Agriculture, Dapoli, Dist. Ratnagiri, Maharashtra*

A field experiment was conducted during *kharif* season 2017 at Experimental Farm, Department of Soil Science and Agril. Chemistry, Balasaheb Sawant Konkan Krishi Vidyapeeth, Dapoli, Dist. Ratnagiri is situated in subtropical region at 17°19' North and 73°1' East longitude having altitude of 250 meters above mean sea level. A field experiment laid out in factorial randomized block design comprising of sixteen treatment combinations with three replicate. The four levels of Nitrogen viz N₀- 0 % RDN, N₁- 40 % RDN through KAB, N₂- 60 % RDN through KAB, N₃ 80 % RDN through KAB and four levels of Silica i.e. Si₀- 0 kg Si ha⁻¹, Si₁- 50 kg Si ha⁻¹ through potassium silicate, Si₂- 75 kg Si ha⁻¹ through potassium silicate, Si₃- 100 kg Si ha⁻¹ through potassium silicate. It was observed that the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

application of 80 per cent RDN through Konkan Annapurna Briquettes (KAB) with Silica @ 100 kg ha⁻¹ which was applied at 7 days after transplanting between four hills was found promising to enhance the growth and yield of *Ratnagiri-24* variety in lateritic soils of Konkan during *Kharif* season.

Keywords: Silica, nitrogen, growth, rice.

MIRACLE PLANT FENUGREEK: A REVIEW

HALDAR, A., MEENA K.C., PATIDAR, D.K. AND SONI, N.

Dept. of Plantation Spices Medicinal and Aromatic Crops, R.V.S. Agriculture University, College of Horticulture, Mandsaur (M.P.) 458001

Fenugreek (*Trigonella foenum-gracum*) is not only a important spices crops but also one of the most promising medicinal herbs, known from ancient times, having nutritional value too. Fenugreek play a important role to cure a number of diseases in human, their green leaves and seeds are used for multipurpose. It is well known for its gum, fibre, alkaloid, flavonoids, saponin and volatile contents. In modern food technology, it is used as food stabilizer, adhesive and emulsifying agent due its fibre, protein and gum content. This crop has the potential to have positive impacts on commercial, agricultural and environmental aspects of agriculture on this continent. In addition to increasing crop diversity this crop will enrich soil by fixing atmospheric nitrogen and would be easy to incorporate into short term crop rotations to help soil conservation and reduce the impact of soil borne pathogens. Fenugreek seeds are a rich source of the polysaccharide galactomannan. They are also a source of saponins such as diosgenin, yamogenin, gitogenin, tigogenin, and neotigogens. About 30% of the seed weight is protein; 5.57.5%, lipids including linoleic acid and linolenic acid; and 15%, galactomannans. The characteristic flavor of the seeds is mainly due to the presence of a small g-lactone, sotolone (volatile compound). Fenugreek has fiber to an extent of 51.7%, containing 19.2% mucilaginous fiber, and 32.5% neutral fiber, that can slow the rate of postprandial glucose absorption. Fenugreek contains approximately 48% saponins and about 1% alkaloids, contributing to bitterness, gastric stimulation, increased acidity, and increased appetite.

BREEDING OF RICE

HAMSA POORNA PRAKASH AND AMIT KUMAR CHAUDHARY

Department of Genetics and Plant Breeding, College of Agriculture¹, Narendra deva University of Agriculture and Technology Kumarganj Faizabad

Rice accounts for about 20% of the world's total grain production, second only to wheat. It is the primary staple for more than 50% of the world's population. An estimated 90% of production and consumption of rice occurs in Asia where the per capita consumption is about 100 pounds, compared to a world average of about 60 pounds and a US average of about 20 pounds. Rice production in the United States is dominated by six states Arkansas, California, Louisiana, Texas, Mississippi, and Missouri, together accounting for about 99% of the total US production. Other minor producers in the United States include Florida, Tennessee, Illinois, South Carolina, and Kentucky. Arkansas leads the production in the United States, with about 100 cwt of rice produced in 2001 on about 1.61 million acres.

Rice genetics is quite extensive. Color development in rice is complex. Anthocyanin pigmentation is controlled by a complementary genetic system, the C-A-P gene system. C is the basic gene for chromogen production, while A controls the conversion of chromogen to anthocyanin, P, which is variable, determines the site of pigment expression (e.g., Pg, Pm, Ps, Px, etc.). A smooth hull is desirable for mechanical harvesting and processing. Pubescence on the surface of the blades and hull is controlled by a dominant gene, glabrous (*gl*).

Keywords :- rice, production, breeding methods, chromogen production etc.

INTEGRATED WEED MANAGEMENT IN SUNFLOWER (*HELIANTHUS ANNUUS* L.)

AS INFLUENCED BY DIFFERENT WEED MANAGEMENT PRACTICES

Hansraj Hans¹, Vikram Bharati², Lokesh Kumar² and Bal Krishna³, Division of Crop Research, ICAR-RCER, Patna, India- 800 014, ² Rajendra Prasad Central Agricultural University, Pusa, Samastipur, Bihar, India- 848 125, BAU, Sabour, Bhagalpur, Bihar, India- 813 210*

Sunflower has emerged as one of the important oilseed crops in India. Among the production constraints weed infestation is one of the major factors for loss in yield. This crop is a poor competitor with weeds due to initial slow crop growth and wider spacing. The initial crop growth period is the most critical stage at which abiotic or biotic stresses affect the crop yield. Therefore, keeping this in a view an experiment was laid out in a randomized block design consisting ten treatments and replicated thrice at the Research Farm of Tirhut College of Agriculture, Dholi, RPCAU, Pusa, Bihar, India. Treatments constituted viz., pendimethalin @ 0.75 kg a.i./ha (38.7 CS new

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

molecule) as pre-emergence, pendimethalin (38.7 CS new molecule) @ 0.75 kg a.i./ha as pre-emergence + one intercultivation at 20 DAS followed by hand weeding at 40 DAS, pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + quizalofop ethyl @ 37.5 g a.i./ha at 20 DAS, pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + propaquizafop @ 62 g a.i./ha at 20 DAS, pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + fenoxoprop ethyl @ 37.5 g a.i./ha at 20 DAS, farmers practice (one hand weeding at 30 DAS), pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + one weeding by power weeder at 35 DAS, one weeding by power weeder at 35 DAS, weed free (two hand weeding at 20 and 40 DAS) and unweeded control. *The soil of experimental site was sandy loam in texture with alkaline pH (8.2), medium in organic carbon content (4.5 g/kg) and available N, P and K.* Weed spectrum of the experimental field consisted of three groups of weeds like grasses, sedges and broad leaved weeds. The maximum seed yield (2149 Kg/ha) and straw yield (4971 Kg/ha) obtained under weed free (twice hand weeding at 20 and 40 DAS) had significantly higher value than pendimethalin (38.7 CS new molecule) @ 0.75 kg a.i./ha as pre-emergence + one intercultivation at 20 DAS followed by hand weeding at 40 DAS, pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + propaquizafop @ 62 g a.i./ha at 20 DAS, pendimethalin (38.7 CS new molecule) @ 1.0 kg a.i./ha as pre-emergence + quizalofop ethyl @ 37.5 g a.i./ha at 20 DAS. Hence, it may concluded that weed free treatment is efficient ecological acceptable integrated weed management practices are essential to achieve a maximum return while reducing the weed population.

BIOCHAR IN INDIAN AGRICULTURE: PROSPECTS AND CONCERNS**HARDEEP SINGH SHEORAN^{1*} AND HARENDER SINGH DAHIYA²**¹Haryana Space Applications Centre, CCS HAU Campus, Hisar-125004, ²State Agriculture Department, Government of Haryana

Climate is one of the key drivers behind agriculture. As climate change is uncertain, agriculture should be climate smart and must include agricultural management practices which include the use of bio wastes that could be able to sustain or improve our soil health. Moreover, increase in atmospheric carbon level is becoming a challenging task for the scientific community. Worldwide, successful implement strategies are being developing to drop down carbon dioxide level from the atmosphere but climate change is a becoming a bigger threat to civilization day by day which must be tackled. Biochar, due to its aromatic structure and long mean residence time in the soil has the potential for long-term carbon sequestration in the soil and offers a significant tool to reduce CO₂ and GHG emissions. The trend obtained from the research studies carried out across the world raised our hopes of achieving the goal of maintain or enhancing the crop productivity coupled with environmental sustainability. Therefore, we need to raise awareness among the scientific as well as farming community about the use of biochar as a sustainable option for climate change mitigation and adaptation.

Key words: Biochar, Climate change, Mitigation, Adaptation and Environmental sustainability

FLY ASH: A POTENTIAL SOURCE OF NUTRIENTS IN AGRICULTURE**HARENDER SINGH DAHIYA^{1*} AND YOGENDRA KUMAR BUDANIA**¹Agriculture Department, Government of Haryana

Coal among all is one of the important non-renewable resources and is considered as the core raw material for generation of energy and plays a key role in meeting the over increasing fossil fuels demands in India and across the world. However, advances in technological sector are leading to exert a great pressure on our valued natural resources such coal etc. Though in preceding few decades various alternate energy sources have come into the limelight, the use of coal as primary source of energy cannot be counter balanced. Despite of the increased efforts to prevent, reduce, reuse and recycle, the appropriate management of fly ash remains a major issue and it is hard truth that to meet the growing energy demand will continue to create various problems that may be environmental, economic and social. These problems are associated with generation of large amount of fly ash and therefore, lack of its judicious use and proper disposal is in question. It has been proved to be a useful supplement for agricultural application in addition to use in cement, bricks and blocks, road embankments, low lying area filling, mine applications, etc. Fly ash, being a good soil ameliorant and source of major and plant nutrients can significantly improve the physio-chemical properties. *Incorporation of fly ash in agricultural soils is best alternate use or way to dispose it* and studies around the world confirmed that fly ash application in agricultural soils have shown promising results with respect to crop production and possess wide prospects of using fly ash in agriculture while providing safe environment by its safe consumption in agriculture.

Key words: Coal, Fly ash, Environment, Agriculture and Productivity

MATURITY AND MATURITY INDICES OF FRUITS AND VEGETABLES**HARENDRA, ASHOK KUMAR AND ABHINAV KUMAR***Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad*

The principles dictating at which stage of maturity a fruit or vegetable should be harvested are crucial to its subsequent storage and marketable life and quality. Fruits harvested too early may lack flavour and may not ripen properly, while produce harvested too late may be fibrous or have very limited market life. Similarly; vegetables are harvested over a wide range of physiological stages, depending upon which part of the plant is used as food. For example, small or immature vegetables possess better texture and quality than mature or over mature vegetables. Therefore harvesting of fruits and vegetables at proper stage of maturity is paramount importance for attaining desirable quality. The level of maturity actually helps in selection storage methods, estimation of shelf life, selection of processing operations for value addition etc. The term maturity is derived Latin word 'Maturus' which means ripen. It is that stage of fruit development, which ensures attainment of maximum edible quality at the completion of ripening process. The maturity has been divided into two categories i.e. physiological maturity and horticultural maturity. Post-harvest physiologists distinguish three stages in the life span of fruits and vegetables: maturation, ripening, and senescence. Maturation is indicative of the fruit being ready for harvest.

Keywords- maturity, storage methods, attaining desirable shelf life, selection of processing etc.

GENETIC VARIABILITY, CORRELATION AND PATH COEFFICIENT ANALYSIS IN BITTERGOURD (*MOMORDICA CHARANTIAL.*)**HARISHANKAR, P.K. SINGH, G.C. YADAV***Department of Vegetable Science- NDUA&TKumarganj, Faizabad (222429) U.P.*

Variability, correlation and Path coefficient among eight horticultural characters of twenty bitter gourd hybrids were studied. High genotypic (GCV) and phenotypic coefficient of variation (PCV) was observed for number of fruits per plant, fruit weight and fruit length whereas low GCV and PCV was observed for days to first male and female flower anthesis (days after sowing). For most of the parameters under study, PCV was found to be higher than GCV. High heritability with high genetic advance (GA) was observed for fruit weight, fruit length and number of fruits per plant which is an indicative of greater proportion of additive genetic variance and consequence a high genetic gain from selection. High heritability with low genetic advance was observed for days to first male and female flower anthesis and days to marketable maturity from anthesis, indicated that non-additive gene effects were involved for the expression of these characters. Higher Genotypic and phenotypic coefficient of variation was recorded for number of fruits per plant, fruit weight and fruit length indicated that, these test hybrids exhibited much variation among themselves with respect to these characters offering more scope for selection. PCV and GCV recorded for days to first male and female flower anthesis was low and in agreement with Islam et al (2009). High heritability coupled with low genetic advance, low heritability with high genetic advance or low heritability and low genetic advance offers less scope for selection because of non additive genetic effects. High heritability coupled with high genetic advance showed greater proportion of additive genetic variance and consequence a high genetic gain expected from selection (Devi and Mariappan, 2013).

GENETIC DIVERGENCE STUDIES IN BITTER GOURD (*MOMORDICA CHARANTIAL.*)**HARISHANKAR, P.K. SINGH, G.C. YADAV, D.P. YADAV, VIJAY KUMAR.***Department of Vegetable Science- NDUA&TKumarganj, Faizabad (222429) U.P.*

An investigation was carried out with ten wild and cultivated cucurbitaceous rootstocks viz., Mithipakal (*Momordica charantia* var. *muricata*), fig leaf gourd (*Cucurbita ficifolia*), pumpkin (*Cucurbita moschata*), zucchini squash (*Cucurbita pepo*), sponge gourd (*Luffa cylindrica*), ridge gourd (*Luffa acutangula*), bottle gour (*Lagenaria siceraria*), ash gourd (*Benincasa hispida*), kumatikai (*Citrullus colocynthis*), African horned cucumber (*Cucumis metuliferous*) on two bitter gourd (*Momordica charantia*) scions viz., Palee F1 and CO 1 for resistance against root knot nematode *Meloidogyne incognita* and Fusarium wilt (*Fusarium oxysporum*). The influence of using different rootstocks on the success percentage of grafting, plant growth, earliness, fruit yield and fruit quality of bitter gourd was also studied to select the best graft combination. The grafting technique followed in this study is side grafting. Screening of rootstocks to *M. incognita* under pot culture condition revealed that the rootstocks viz., kumatikai (*Citrullus colocynthis*) followed by African horned cucumber (*Cucumis metuliferous*) and pumpkin (*Cucurbita moschata*) which exhibited resistant reaction and sponge gourd (*Luffa cylindrica*) and mithipakal (*Momordica charantia* var. *muricata*) showed moderately resistant reaction which can be used for grafting in bitter gourd. The results on grafting studies revealed that Palee F1 grafted onto pumpkin rootstock recorded the highest success percentage followed by Palee F1 grafted onto sponge gourd rootstock at 15, 30 and 45 days intervals. From this study pumpkin and sponge gourd could be identified as the best rootstock for grafting with bitter gourd. Evaluation of graft combinations based on the performance of biometric, biochemical and quality traits revealed that the graft, Palee F1 grafted onto pumpkin rootstock was found to be the best as it expressed good performance in terms of earliness, yield and yield contributing traits and quality parameters.

GENETICS OF YIELD AND YIELD COMPONENTS IN BITTER GOURD (*MOMORDICA CHARANTIA* L.) UNDER SALINITY**HARISHANKAR, P.K. SINGH, G.C. YADAV, ANUPAM DUBEY,***Department of Vegetable Science- NDU&TKumargunj, Faizabad (222429) U.P.*

An investigation was carried out with twenty two bitter gourd genotypes collected from different geographical locations under saline soil. The genetic divergence studies based on fourteen quantitative characters resulted in the formation of six gene constellations, with a maximum of fourteen genotypes constituted by cluster I. The eight genotypes viz., MDU 1, CO 1, IC 85643, Bikaneer 1, Bikaneer 3, BGS 1, Vadipatti Local and Paravai Local identified from the six clusters based on genetic diversity were crossed in a full diallel fashion to get fifty six direct and reciprocal cross combinations. All the fifty six F1 hybrids and the eight parents were evaluated for fifteen characters under saline sodic condition to unravel information on the nature and magnitude of gene action, combining ability and heterosis to identify superior crosses for heterosis as well as recombination breeding. Considering the per se performance for the two important traits viz., yield of fruits per vine and leaf sodium: potassium ratio as an index of salt tolerance, two parents (IC 85643 and BGS 1) and six hybrids (IC 85643 X Bikaneer 1, Bikaneer 1 X MDU 1, Bikaneer 1 X Bikaneer 3, Bikaneer 3 X BGS 1, Bikaneer 1 X CO 1 and Bikaneer 3 X Paravai Local) were considered superior. Based on the gca effect, the parent Bikaneer 1 was found to be the best combiner for seven of the fifteen characters studied, including yield of fruits per vine and leaf sodium: potassium ratio. The analysis of genetic components and genetic ratios also revealed the existence of both additive and dominant gene action for majority of the traits. The prevalence of dominant gene action was recorded for yield of fruits per vine and leaf sodium: potassium ratio.

STUDIES ON GENETIC VARIABILITY OF YIELD AND YIELD ATTRIBUTES IN MORPHOLOGICALLY DIVERSE BOTTLE GOURD [*LAGENARIA SICERARIA* (MOL.).**HARISHANKAR, P.K. SINGH, G.C. YADAV***Department of Vegetable Science- NDU&TKumargunj, Faizabad (222429) U.P.*

The present investigation entitled 'Studies on genetic variability of yield and yield attributes in morphologically diverse bottle gourd [*Lagenaria siceraria* (Mol.). was carried out at the Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) with the following five objectives i. To record biodiversity in fruit and seed characters ii. To identify high yielding genotype(s) among morphologically diverse groups of bottle gourd genotypes, iii. To identify association of morphologically distinct bottle gourd genotypes with yield and yield attributes, if any, iv. To study the coefficient of variability, nature & magnitude of heritability, and genetic advance of agronomic traits, and v. To study correlation coefficients among the yield and yield attributes. The experiment was conducted in Randomized Block Design with three replications. Observations were recorded on 12 economic traits viz., node number to first staminate flower anthesis, node number to first pistillate flower anthesis, days to first staminate flower anthesis, days to first pistillate flower anthesis, days to first harvest, average fruits length/polar length (cm), average fruit circumference (cm), average fruit weight (kg), average number of fruits per plant, vine length at the time of last harvest (m), number of primary branches per vine at the time of last harvest and average fruit yield (kg/plant). The highest fruit yield per plant of 7.95 kg, recorded in NDBG-619-11-2 followed by Narendra Dharidar (7.83 kg), NDML-SS-9 (6.66 kg), NDBG-701 (6.22 kg), and NDBG-703 (6.22 kg).

GENETIC DIVERSITY, HERITABILITY AND MORPHOLOGICAL CHARACTERIZATION IN BOTTLE GOURD (*LAGENARIA SICERARIA* MOL.)**HARISHANKAR, P.K. SINGH, G.C. YADAV***Department of Vegetable Science- NDU&TKumargunj, Faizabad (222429) U.P.*

A field experiment was conducted at Vegetable Research Farm, Kumargunj, NDU&T., Faizabad (UP.) during winter season in the year 2016-17 and 2017-18. The present investigation was undertaken with 16 genotypes of bottle gourd for evaluating their performance for various horticultural characters. There was a great deal of significant variation for all the characters among the genotypes. The significantly higher yield in Narendra Shivani (311.53 q/ha) might be due to higher values of yield attributes (fruit set percentage, fruit length, number of fruit per vine, fruit weight and fruit width) followed by Narendra Sanker Lauki. Whereas, the lower yield was found in case of Narendra Jyoti (101.86 q/ha), respectively due to lower yield attributes. High genotypic co-efficient of variation (GCV) was observed for fruit weight (39.48%). In all cases, phenotypic co-efficient variances were higher than the genotypic co-efficient variance. High heritability with high genetic advance in percent of mean was observed for all characters were under additive gene control and selection for genetic improvement for this trait would be effective. Among all the genotypes, Narendra Shivani, Narendra Sanker Lauki, and NS 421 gave promising results. The bottle gourd can be easily distinguished from other pumpkin varieties by its white flowers and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

characteristic fruit, seed and leaf shapes (Cutler and Whitaker, 1967). Bottle gourd variability has been studied by many authors, including Heiser (1979); Marimoto and Mvere, (2004); Marimoto et al. (2005) etc. Studies in India demonstrated the significant regional variability (Sivaraj and Pandravada, 2005). These findings were in line with the results reported by Sakar (2004), who reported fruit size and shape as the most apparently distinguishable morphological traits in the Mediterranean region.

ALLELE MINING AND ITS APPLICATIONS IN CROP IMPROVEMENT**HARIKANT YADAV* AND HIMANSHU CHAUDHARY**

Department of Genetics and Plant Breeding, College of Agriculture, G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand

Allele Mining is an approach that is used to dissect naturally occurring allelic variations or suitable alleles of a candidate gene controlling key agronomic traits which has potential in crop improvement. It helps in tracing the evolution of alleles, identification of new haplotypes and development of allele-specific molecular markers for use in marker-assisted selection (MAS). In general, there are two approaches available for allele mining: (1) Modified TILLING (Targeting induced Local Lesions in Genome) (2) Sequencing based allele mining. TILLING is one of the reverse genetics approach where mutations are induced and useful mutations are detected. Eco-TILLING an extension of TILLING allows the rapid detection of variation in many individuals and is cost effective because only one individual for each haplotype needs to be sequenced. The technology is applicable to any organism including those that are heterozygous and polyploid. Recently, a rapid and cost effective method for detecting novel allelic variants of known candidate on agarose gel and its utility in candidate gene mapping has been described called sequence based allele mining. This technique involves amplification of alleles in diverse genotype through PCR followed by identification of nucleotide variation by DNA sequencing and it would help to analyse individuals for haplotype structure and diversity to infer genetic association studies in plant. Allele mining can be successfully employed for the detection of alternative form of gene of interest in diverse genetic resources and plays an important role in realizing the worth of plant genetic resources.

Key words: Allele mining, haplotypes, marker assisted selection, TILLING, Eco-TILLING, Candidate gene.

INITIATIVE FOR DOUBLING FARMERS INCOME IN HORTICULTURE**HARIOM KATIYAR, S.K. LODHI AND KALPANASINGH**

Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut

Horticulture has emerged as a core sector of agriculture over the past decade, growing steadily in annual area coverage and output. By 2022, 6.5 lakh ha of additional area will be brought under horticulture crops through area expansion and 1.75 lakh ha of additional area will be brought under protected cultivation. Horticulture is seen as optimal option for crop diversification in agriculture. The per unit earning capacity of farmers is much higher than in case of food grains and it also addresses environmental concerns. Nevertheless, most horticultural output requires specialised market linkages and connectivity, post harvest infrastructure and to make this sector more remunerative, there is a need to address the constraints involved. The productivity of vegetables and fruits was negligible in case of aromatic crops and spices. Therefore, there is more need to focus on aromatic crops and spices in state programme as compared to other commodities. Honey production is a potential sector in horticulture; hence apiculture should be integrated with fruit and vegetable production for increasing the income of farmers. Productivity growth in fruits and vegetable was meagre over the past decade. This is only due to non-availability of quality planting material, dwindling status of natural resources, abundance of resource poor farmers and low adoption of modern technologies. The challenge is to enhance productivity by increasing the factor productivity of all the horticultural production inputs, and at the same time sustaining it by adoption of good practices and precision farming principles. Hence, situation specific modern technologies should be identified/developed, refined/validated and popularized. High cost of input in horticulture crops, prevalence of old and senile orchards, unorganized supply chain are the major bottle neck, therefore, adoption of organic agriculture practices and farming system approach should be promoted for decreasing input cost and ultimately increasing the income. Moreover, rejuvenation of old and unproductive orchard and organized marketing are also very important for getting remunerative income. Facilitation of micro-irrigation in horticulture sector in rainfed areas. As reported 30% produce of horticultural crops are being spoiled due to their perishability. So their perishable nature should be judiciously targeted based on assessment of production and availability of market to escape unexpected low prices of produce due to high level of production. Based on a survey, it is found that the major problems faced by horticulture farmers are finance, marketing, labour, storage, maintenance, education etc. Major thrust areas for horticulture development are cluster approach linked with post-harvest management and marketing, market intelligence to promote market led production, quality seeds and planting material, adoption of improved varieties and rejuvenation with improved cultivars, hi-tech horticulture, precision farming and high density plantations to double our farmers income.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**APICULTURE****HARISH KUMAR NAIDU***Maya Group Of Colleges.*

Apiculture, the study and keeping of bees, can be expanded into a small business. Honey has a long and distinguished history in the human diet. Employing both sound beekeeping and business practices can generate a substantial income from the sale of honey. The main objective was to assess the potential of apiculture as an alternative source of income generation through survey and field trials. Cost benefit analysis was also compared with traditional cereal crops production. The field trial employed the construction, baiting and mounting of Kenyan top bar beehives and for the survey; questionnaire was designed to collect information on beekeeping. A profit of GHc 462.00 could be obtained from apiculture using 6 beehives on an acre of land compared to profit of GHc 148.00 could be obtained from an acre of maize farm and with a profit difference of GHc 314.00 proved that apiculture could be a good alternative source of income. Apiculture is a very good business venture as an alternative source of income generation and has potential to improve the economic status of people in the Upper East Region of Ghana. More farmers, women and unemployed youth in the region are advised to take up apiculture to generate more income and improve their economic status. Government agencies such as SADA and NGOs involved in afforestation should also promote apiculture to improve the vegetation of the region.

HORTICULTURAL INNOVATIONS, FOOD PROCESSING AND VALUE ADDITION BREEDING FOR NUTRACEUTICALS IN BELL PEPPER**'HARNOOR KAUR DHILLON, 'SHUBHAM KUMAR, 'SUNIL KUMAR, 'PRIYANKA, 'ESHANEE, 'SHIVANI CHAUHAN AND 'BHALLAN SINGH SEKHON***CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) - 176062*

Capsicum or bell pepper is a cool season crop. It is mostly eaten in cooked form in India (green capsicum) whereas in USA and Europe it is relished in salads, so red and yellow ones are more popular. Capsicum is also consumed in the form of pickles, baked and stuffed form. Red and yellow capsicum are increasingly becoming popular in India, being used in pizzas and other processed foods. It is low in calories and rich in carbohydrates mainly present in the form of glucose and fructose. It is very rich source of ascorbic acid which can be justified by the fact that about 400gm of raw bell pepper contains enough ascorbic acid to supply daily requirement of nine persons. It is available in wide range of colours like- green, red, yellow, orange, chocolate, purple and blue. It is rich in carotenoids like capsanthin (red), violaxanthin (yellow), lutein (green), quercetin and luteolin. Quercetin plays a major role in combating diseases like cancer and heart ailments. Luteolin nutraceuticals has been isolated from sweet pepper and it has eye benefits. Red pepper and orange pepper are more nutritive than the green ones. These contain eleven times more vitamin A and 4 times more vitamin C than the green pepper. Yellow peppers reduce age related degeneration, risk of prostate cancer, lower cholesterol and blood pressure. Purple peppers support retinal health, boost immune system, reduce tumor growth and fight inflammation. Plant breeding programs in bell pepper are mostly concerned on improving yield, resistance to diseases, tolerance to abiotic stresses, increasing shelf life, developing early and late maturing varieties. With the people becoming aware about the health benefits of consuming colourful vegetables giving origin to the concept of rainbow cultivation it has become imperative that nutraceutical and edible colour rich varieties are bred. This can be accomplished by combining the conventional breeding methods with molecular biology. Identification of sources of variation for nutraceuticals content can be accomplished by screening germplasm collections, evaluating morphological characters and origin, evaluating mutations in key genes. Nutraceutical rich varieties can be developed by identifying important bio-active compounds present in sweet pepper, searching sources of variation with breeding potential and discussion of breeding strategies and developing suitable ideotype.

Keywords: Capsicum, conventional breeding, nutraceuticals, quercetin, rainbow cultivation

SITE-SPECIFIC NUTRIENT MANAGEMENT (SSNM)**HARPUNEET KAUR***L-2017-A-6-M Msc Agronomy, PAU, Ludhiana*

Site-specific nutrient management (SSNM) as developed through partnerships of IRRI with national organizations across Asia provides the principles and pointers that modify farmers to use fertilizer to optimally match the requirements of their rice wheat crop in an exceedingly specific field and season. It aims to attain high yield and high potency of nutrient use, resulting in high money price of the harvest per unit of fertilizer endowed. A lot of the nutrients needed by rice plants come back from the soil however the availability of nutrients isn't ready to meet the nutrient necessities for realizing higher rice yields. The employment of fertilizers is thus, essential to fill the gap between the crop desires for nutrients and also the offer of nutrient from soil. For economical and effective SSNM, the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

employment of soil and plant nutrient standing sensing devices, remote sensing, GIS, call support systems, simulation models and machines for variable application of nutrients play a crucial role. The Leaf colour chart is an efficient tool for adjusting fertilizer N use to field-specific desires of rice wheat for supplemental N. Farmers' historical use of fertilizer P and their possible crop yields will be accustomed estimate field-specific fertilizer P desires. Straw management, soil K-supplying properties and possible crop yields will be accustomed estimate field specific fertilizer K desires. The appliance and management of nutrients are dynamically adjusted to crop desires of the placement and season. The principles of SSNM are referred to as the "4 R", go back to a minimum of 1988 and are attributed to the International Plant Nutrition Institute. They are right product, right rate, right time and right place. The SSNM reduces the wastage of fertilizers by preventing excessive use of fertilizers and avoiding fertilizer application once the crop doesn't need nutrient inputs. It additionally assures that N, P and K are applied within the quantitative relation needed by the supposed crop. Need of SSNM is due to yield stagnation/decline in modern present agriculture, over mining of nutrients, emerging nutrient deficiencies, water quality deteriorations, variations in input levels, development of soil salinity/sodicity/acidity and low fertilizer use efficiency. Challenges to adoption of SSNM are technology and data requirements, availability of fertilizers and variable economic benefit.

The site-specific nutrient management (SSNM) could be a new and helpful thought. This makes the economical utilization of nutrients by crop plants and avoids the wastages of fertilizers. The environmental footprints of chemical fertilizers also are reduced. Farm profit and NUE increase convincingly by victimization this novel thought.

FREEZE DRYING: A EFFECTIVE WAY OF DRYING OF FRUITS AND VEGETABLES

HARSH P. SHARMA¹, ANURAG NEMA¹, VAISHALI², HIRALA. PATEL¹

¹College of Food Processing Technology and Bio-energy Anand Agricultural University, Anand 388110, ²Sardar Vallabh Bhai Patel University of Agriculture and Technology, Meerut-250110

Freeze drying is the most prominent example of separation by sublimation. In Freeze drying water is removed as vapour from a frozen substance. Freeze drying process is subdivided into three steps i.e. prefreezing, sublimation drying and the secondary drying. Fruits and vegetables are dried to enhance storage stability, minimize packaging requirement and reduce transport weight. Preservation of fruits and vegetables through drying based on sun and solar drying techniques causes poor quality and product contamination. In freeze drying due to the absence of water and the presence of low temperatures, most of deterioration and microbiological reactions are stopped which gives a final product of excellent quality. Industrial application of freezing drying includes some exotic fruits and vegetables, pineapple, Barbados cherry, guava, papaya, strawberries, guava pulp, Mango pulp, Orange juice, passion fruit juice, carrot, capsicum, mushrooms, onion stalk soup ingredients, coffee. Freeze drying at present finds its largest application in food dehydration. A high cost of the freeze-drying still limits the wide-scale application in the food industry.

IMMERSION FREEZING: A NOVEL TECHNOLOGY FOR LONG-TERM STORAGE OF FROZEN FOODS

HARSH P. SHARMA¹, VAISHALI², ANURAG NEMA¹, KHUSHBU VAHORA¹

¹College of Food Processing Technology & Bio-energy, Anand Agricultural University, Anand-388110, ²Sardar Vallabh Bhai Patel University of Agriculture and Technology, Meerut-250110

Immersion freezing (IF) consists of a food product freezing by direct immersion in a refrigerant that remains liquid throughout the process. Refrigerated aqueous solutions of propylene glycol, sodium chloride, calcium chloride and mixture of sugars and salts can be used as medium of freezing. Immersion freezer consists of a tank with a cooled freezing medium. The product is immersed in this solution while being conveyed through the freezer. This requires a separate mechanical refrigeration system to cool the freezing medium. This process is different from other freezing techniques as the food is in direct contact with the liquid freezing medium, allows intimate contact of every surface of the material with the freezing medium and thus ensures very efficient heat transfer. It is the most rapid way of freezing since liquids have better heat conducting properties than air. The freezing rate of IF is 10 times higher than that of air-blast freezing as it allows rapid nucleation and formation of small ice crystals. The average size of ice crystals is <200 µm. For the successful freezing, product should be greater in density than the solution. IF is ideal for unpacked Fruits, meat and sea foods, also for freezing marinated or glazed products, and for creating a highly adhesive surface for accepting a glaze post-freeze. A commonly seen problem in this freezing system is dilution of the solution with the product, which can change the concentration and process parameters. Thus, in order to avoid product contact with the liquid refrigerant, flexible packaging can be used. The immersion freezing technology improves the overall quality and greatly extends the shelf-life. Therefore, IF should be considered as a promising novel technology for long-term storage of frozen foods.

FLUIDIZED BED FREEZER FOR GREEN PEAS**HARSH P. SHARMA¹, ANURAG NEMA¹, VAISHALI², AND HARSH M. RAVAL¹***College of Food Processing Technology and Bio-energy, Anand Agricultural University, Anand-388110, ²Sardar Vallabh Bhai Patel University of Agriculture and Technology, Meerut-250110*

Fluidized bed freezing is used extensively throughout the world to freeze various solid food particles ranging in size from peas to strawberries can be fluidized by forming a bed of particles 1-5 in. deep on a mesh belt or mesh tray and then forcing air upward through the bed at a rate sufficient to partially lift or suspend the particles. This tumbling exposes all sides of the food to the cold air and minimizes the resistance to heat transfer at the surface of the food. In some designs there are two stages: after initial rapid freezing to produce an ice glaze on the surface of the food. Formation of glaze is useful for many products having tendency to clump together. There are a number of advantages of fluidized bed freezing over the conventional freezing methods. In fluidized bed freezing heat transfer as well as rates of freezing is very rapid with this; less product dehydration and less frequent defrosting of equipment also take place. A major disadvantage of fluidized bed freezing is that large or non-uniform products cannot be fluidized at reasonable air velocities. Fluidized bed freezing is highly suited to the production of individual quick frozen (IQF) foods.

STUDIES ON SEAWEED GRANULES (SOLIGRO GR.) AND NITROGEN DOSES ON GROWTH AND YIELD OF HYBRID MAIZE CULTIVARS (ZEA MAYS L.)**HARSHITA SHARMA, RAM PYARE AND GAUTAM VEER CHAUHAN***Department of Agronomy, C.S. Azad University of Agriculture & Technology, Kanpur-208002 (UP), India*

Maize (*Zea mays L.*) is one of the most important cereal crops next to wheat and rice in the world. In India, it is third most important crop after rice and wheat. Maize is grown throughout the year in India, but mainly as *kharif* crop. Maize is being consumed both as food and fodder and also required by the various industries to produce agro product. In the present scenario the demand for maize is found to be increasing not only for human consumption, but also as livestock feed and as an industrial raw material. The sudden increased demand in industrial use of maize as bio-fuel production is likely to create an additional demand for maize in the coming decades with the increase in industrial requirements and value-added foods for a growing economy and population, making maize to continue holding its share as a significant crop. New production technologies of seaweed manure with nitrogen doses offer great promise for increasing production to meet the growing demands of consumers and have favorable impacts on physical and chemical properties of soil. Studies have demonstrated that the majority of our food today is lacking in minerals, which is linked with the causes of our major health problems. Organic Seaweed fertilizers include Magnesium, Potassium, Zinc, Iron and Nitrogen-all of which are beneficial for plants, human and livestock. Seaweed has more than 70 minerals, vitamins and enzymes. Being a crop, maize shows relatively high responses to above combination of seaweed manure and nitrogen fertilizer as compared to other staple food crop, hence, Maize crop becomes an interest of study. There arises a strong need to incorporate such strategies that seek to meet future food demands of India's ever increasing population. Such kind of strategy will have to feature the use of novel organic fertilizers such as seaweed.

Key word: Seaweed, Nitrogen doses, Maize cultivars.

IN-VITRO EVALUATION OF SYSTEMIC FUNGICIDES AGAINST *FUSARIUM OXYSPORUM* F. SP. *LYCOPERSICI* AND THEIR COMPATIBILITY WITH BIOAGENTS**HARSHITA¹, ANKITA SINHA², U.K. TRIPATHI¹, SHUBHA TRIVEDI¹, J.B. KHAN¹, ABHISHEK MISHRA¹ AND SUPRIYA DIXIT¹***¹Department of Plant Pathology, Chandra Shekhar Azad University of Agriculture and Technology, Kanpur, U.P, India-208002, ²Rajendra Prasad Central Agricultural University, Pusa (Samastipur), Bihar, India-848125*

Fusarium oxysporum f. sp. *lycopersici* causing tomato wilt is highly destructive soil borne pathogen and is a major limiting factor in the production of tomato. Application of fungicides is commonly used to effectively control the disease, although they are undesirable due to environmental consequences. To cope with these problems, use of bio-control agents alone or in integration with suitable systemic fungicides may be advised to the farmer as an eco-friendly approach for profitable farming. Therefore, current study was carried out to evaluate different concentrations of commercially available potential systemic fungicides like Topsin M and Carbendazim *in-vitro*, for their efficacy against *Fusarium oxysporum* f. sp. *lycopersici* and to test their compatibility with potential fungal and bacterial bioagents in order to determine whether they can be used in combination. Screening of Carbendazim and Topsin M at three concentrations (50 ppm, 100 ppm and 200 ppm) by poisoned food technique revealed that Carbendazim at 200 ppm has the strongest anti-mycotic potential followed by Carbendazim at 200 ppm showing 96.36 and 94.72 percent inhibition respectively. The compatibility of *Trichoderma harzianum* with systemic fungicides was tested *in-vitro* by poisoned food technique and the results indicated that lesser concentration of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

the two systemic fungicides had lesser inhibitory effect as compared to higher concentration. Topsin M @ 200 ppm showed maximum percent inhibition (80.19) followed by Carbendazim @ 200 ppm and Topsin M @ 100 ppm with 76.92 percent inhibition. Similarly, two potential bacterial antagonists viz. *Bacillus subtilis* and *Pseudomonas fluorescens* were tested *in vitro* for their compatibility with different concentrations of systemic fungicides using well diffusion technique and absence of a distinct inhibition zone around the wells indicated that these two bacterial bio-control agents were compatible with different concentrations (50 ppm, 100 ppm, 200 ppm) of systemic fungicides (Carbendazim and Topsin M).

HYBRID RICE: DEVELOPMENT, CONSTRAINTS AND PROSPECTS A REVIEW

HAUSILA PRASAD SINGH¹, MONICA JYOTI KUJUR² AND SONIKA KALIA³

¹Department of Plant Breeding and Genetics, ³Department of Agricultural Biotechnology, CSK Himachal Pradesh Agricultural University, ²Department of Plant Breeding and Genetics, Jawaharlal Nehru Krishi Vishwa Vidyalaya

Rice (*Oryza sativa* L.) is the world's most important cereal crop that is consumed by a large part of the world's population after wheat and maize. It is the staple food for more than half of the world's population and global rice demand is estimated to rise from 8.52×10^8 t in 2035. More than 90% of the world's rice is produced and consumed in Asia. Hybrid rice production is one of the best practically feasible and readily adaptable one options to enhance the productivity. Hybrid rice technology plays important role in increasing the rice production. The main reason for the cultivation of hybrid rice is to obtain better yield followed by higher pricing ability, better taste, higher profitability, suitable for parboiling, better resistance to pests and diseases. The increase in rice yields due to hybrid rice has, in turn, improved food security for an estimated 60 million additional people per year.

EFFECT OF NUTRIENT MANAGEMENT ON THE PERFORMANCE OF ONION (*ALLIUM CEPA* L.) CV. AGRIFOUND LIGHT RED.

***HEMASOLANKI, **V.N.MISHRA, *DEEPAK KARAN AND *RAJIT**

E-mail : deepakkaran012@gmail.com

Onion (*Allium cepa* L.) Belongs to the family Alliaceae. It is a herbaceous annual for the edible bulb production and biennial for the seed production. Onion is like for its flavour and pungency which is due to the presence of a volatile oil allyl propyl disulphide organic compound rich in Sulphur. Onion bulbs is a rich source of minerals like phosphorus, calcium and carbohydrates. Keeping these importance's the present investigation was conducted at the Department of Horticulture Raja Balwant Singh College, Bichpuri, Agra during 2016-17. The experimental variety was Agri found light red transplanted at 15×10 cm with having 8 treatment combinations viz. T₁(RDF), T₂(100% RDF +Azotobacto), T₃(100% RDF+FYM), T₄(100% RDF+ Azotobactor+ FYM), T₅(80% RDF+ Azotobactor +FYM), T₆(80%RDF+FYM), T₇(80% RDF+ Azotobactor) and T₈(control). The experiment was conducted under Randomized Block Design with three replication. On the basis of analysed data recorded during experimentation, the significant effect was found among between the treatment combinations. The significantly maximum plant height(50.14cm), number of green leaves(8.65), maximum length of leaf(45.53cm), maximum fresh weight of tops at peak stage of growth (45.34gm), maximum fresh weight of bulbs(84.32gm), maximum diameter (6.9 cm) and the maximum bulb yield per hectare(339.58 qt.) Were recorded from treatment T₄(100% RDF +Azotobacter +FYM).

SELECTION FOR YIELD, STABILITY AND RESISTANCE TO WILT SIMULTANEOUSLY FOR DESI CHICKPEA IN NORTH EAST PLAIN ZONE OF INDIA

HEMANT KUMAR, G.P.DIXIT, AND A.K. SRIVASTAVA

ICAR-IIPR Kanpur

Development and use of high-yielding genotypes, resistant to the prevalent wilt (*Fusarium oxysporum*) in a given area is the most practical and cost-efficient individual disease control measure for management of the disease and accordingly genotypes are promoted in next level of trial in particular to AICRP system. Taking consideration of wilt infestation along with genotypic stability and average yield an index has been developed and computed to rank the chickpea genotypes for the promotion of genotypes in next level of the trial. Average yield, genotypic stability and percentage wilt infestation are three components in this index. For stability component additive main effects and multiplicative interaction (AMMI) model is used, as it captures a large portion of the interaction sum of squares and often provides meaningful interpretation of data to support a breeding program such as genotypic stability. Based on the AMMI model, this index has been used to rank the genotypes along with wilt infestation and average yield. This index is the weightage of wilt infestation, genotypic stability and yield component and higher the index value better is the genotypes. The index of 31 promising

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

chickpea genotypes, evaluated in North East Plain Zone of All India Coordinated Research Project on chickpea program during 2016-17, were computed with 10% weight to wilt infestation, 10% weight to stability component, and 80% weight to average yield. Ranking of genotypes are done based on this index and genotype CSJ907 with index value 1.1658 was found best genotype followed by BRC-1 with index value 1.1025 and RKG1375 with index value 1.0919. Therefore, these three genotypes may be used by the chickpea breeder for developing high yield, stable and wilt resistance chickpea lines.

EDIBLE COATING IN FRUIT CROPS

HEMANT SAINI* AND POONAM SAINI

Department of Horticulture, College of Agriculture, CCSHAU, Hisar- 125 004 (Haryana)

Edible films are defined as a thin layer of material which can be consumed and provides a barrier to moisture, oxygen and solute movement for the food. The material can be a complete fruit coating or can be disposed as a continuous layer between food components. Application of waxes and coatings has long historic background and commercially applied about sixty years ago. Edible films can be formed as food coatings and free-standing films, and have the potential to be used with food as gas aroma barrier. The films can enhance the organoleptic properties of packaged foods provided they contain various components (flavorings, colorings, sweeteners). Components used for the preparation of edible films can be classified into three categories: hydrocolloids (such as proteins, polysaccharides, and alginate), lipids (such as fatty acids, acylglycerol, waxes) and composites. Chitosan is often considered to be the ideal preservative coating for fresh fruit because of its excellent film-forming and biochemical properties. These coatings offer many advantages, such as improved appearance, antimicrobial properties, selective permeability to gases (CO₂ and O₂), good mechanical properties, non-toxicity, non-polluting properties and low cost. The use of edible coatings with certain additives, such as those with essential oils (EOs) incorporated, has been particularly highlighted over the years, because of its effect on extending the shelf life and facilitating the processing and consumption of fruits. Edible coatings create a modified atmosphere around the fruit by providing a semi-permeable barrier to O₂ and CO₂, thereby reducing respiration and oxidation reaction rates. Edible coatings protect perishable fruits from deterioration by retarding dehydration, suppressing respiration, improving the textural quality, helping retain the volatile flavour compounds and reducing the microbial growth. In this way, the application of edible coatings on fresh fruits can provide an alternative method to extend the post harvest life, reducing quality changes and quantity losses, and can also result in the same effect as modified atmosphere storage in modifying the internal gas composition.

STUDIES ON THE INFLUENCE OF FRENCH MARIGOLD IN NEMATODE MANAGEMENT IN BRINJAL CROP.

DR HEMLATA PANT

Department of Zoology, C.M.P.P.G. College Allahabad

French marigold has been found to suppress nematode population drastically in solanaceous crops. It was found that its roots releases chemicals which are nematicidal in nature. Three methods were used to apply French marigold with the aim to suppress nematodes population. In first method double row of brinjal plantation followed by 10 dense rows (4x4cm) of French marigold plant and this sequence was followed in 10 m square area. In the second method alternate planting of French marigold and brinjal Plant was done. In third method around the brinjal plant dense planting of French marigold in triple rows was done. It was found that the first method in which double row of brinjal along with 10 dense rows of French marigold was best in plant growth development and yield. Root development was normal and rarely knots were observed. The second best result was recorded in second method followed by third method. All the treatments were better over Control. The exudate of marigold plant proved entomophagous. The other reason might be high concentration of organic substances which proliferate fungus population and ultimately suppress the nematodes population significantly.

FARMER PRODUCER COMPANY (FPC): A NEW CO-OPERATISM TOWARDS DOUBLING FARMER'S INCOME IN INDIA

HIMADRI ROY^{1*}, AWADESH KUMAR SINGH², HIMANSHU SHEKHAR RAI³

Scholar, Department of Extension Education, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi. ² Subject Matter Specialist (Agril. Extension), KVK, Pratapgarh, Uttar Pradesh, India.

In India, the income received by a farmer from agriculture is insufficient to address agrarian distress and to reduce poverty. Hence, aiming to boost the Indian agriculture, the Government has set this lofty goal of doubling farmer's income by 2022. To achieve this target, collectivization of producers, especially small and marginal farmers, into producer companies to improve their bargaining power

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

through backward and forward linkages has emerged as one of the most effective pathways. Farmer Producer Company (FPC) can be seen as hybrid between private company and cooperative society. The producer-company concept is aimed to combine the efficiency of a company with the spirit of traditional cooperatives. The rationale behind Farmer Producer Companies is that farmers, who are the producers of agricultural products, can form groups and register themselves under the Indian Companies Act. FPC aims to integrate smallholders into modern supply networks by minimizing the involvement of middle-men in marketing of produce and reducing the transaction and coordination costs. FPC facilitates various services to its members like financial services, input supply services, value addition services, procurement and packaging services, networking Services etc. Through the Equity Grant Fund scheme, eligible FPCs receive a grant equivalent in amount to the equity contribution of their shareholder members, thus it doubles the overall capital base of the FPC. In a nutshell Farmer Producer Companies if handled and nurtured properly, can make a sustainable long term change in the lives of our small farmers by doubling their income by eliminating vulnerability of the current market and environmental situations.

ROLE OF SYNTHETIC CHROMOSOME TECHNOLOGY IN CROP IMPROVEMENT

HIMANSHU CHAUDHARY*, AMIT KUMAR GAUR AND HARIKANT YADAV

Department of Genetics and Plant Breeding, College of Agriculture, G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand

Genetic engineering is a scientific tool used in field of plant, animal and human sciences. Plant genetic engineering technology has changed the face of plant sciences and the first generation of transgenic crops has become the most rapidly adopted technology in modern agriculture. But genetic engineering has some boundaries and therefore still there is a need of new technologies to overcome issues like gene stacking, transgene position effects and insertion-site complexity. The recent strategy that researchers have developed to overcome those boundaries is the development of plant artificial minichromosomes for delivery of large DNA sequences, including large genes, multigene complexes, or even complete metabolic pathways. A minichromosome is an extremely small version of a chromosome that has been produced by *de novo* construction using cloned components of chromosomes or through telomere-mediated truncation of endogenous chromosomes. It has created a new paradigm for all the agricultural researchers to use the minichromosome techniques for crop improvement. Engineered minichromosomes also offer huge opportunity to get better crop performance. With rapidly expanding research in minichromosome as a second generation genetic engineering tool we can hope that it will bring a new generation of improved crop species to meet the global demands. Engineered minichromosomes establish the means to add or subtract multiple transgenes, multigene complexes, or whole biochemical pathways to plants to change their properties for agricultural applications or to use plants as factories for the production of foreign proteins or metabolites.

Key words: Synthetic chromosome, Genetic engineering,

IMPACT OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH, YIELD AND NUTRIENT UPTAKE BY MARIGOLD (*TAGETUS ERECTA*) WITH SPECIAL REFERENCE TO MINIMIZE THE EFFECT OF CHEMICAL FERTILIZERS ON ENVIRONMENT

HIMANSHU KAUSHIK, J.P. SINGH, SUDHANSHU KAUSHIK* AND RAJAT SINGH[#]

*Dept. of Horticulture, Gochar Mahavidyalaya, Rampur Maniharan, *Dept of Environmental Science, Dev Sanskriti Vishwavidyalaya, Haridwar, #SBVP University, Modipuram*

The present study, deals about the effect of INM on growth, yield and nutrient uptake by *Tagetis erecta* to minimize the effects of chemical fertilizers. In India, agriculture is the main economic gainer, but after green revolution the traditional agriculture was replaced by modern agriculture. Modern agriculture is good economic gainer and provides the financial growth to the country. This is the one phase of the coin let see another phase of the coin, this Agriculture has degraded the environmental quality in enormous manner. We have exhausted the environmental resources in very short period of time for fulfill the demand of agricultural product for the human being. No doubt agriculture is the necessity for the human being, we can't survive without crop development and variations, but the time has been come to accept the concept of sustainable agriculture for long time survival on the earth planet. INM is the technique to grow crops by the using of minimum amount of chemical fertilizers and resources. In this study we have carried out an experimental research on the effects of nutrient management on the selected crop. By accepting the nutrient management plan, we will be able to give more enhanced and advanced quality of crops to our next generation without causing the degradation of the environmental quality. So INM is the technique of great concern not only for the enhancement the quality of crops but for the human welfare also by which we will be able to provide eco-friendly product to the human society.

EFFECT OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH ATTRIBUTES OF KALMEGH

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**[ANDROGRAPHIS PANICULATA (BURN.F.) WALLNEES]****HIMANSHU VERMA*, M. S. NEGI**, B. S. MAHAPATRA** AND ANIL SHUKLA*****Department of Agronomy, College of Agriculture, GBPUAT, Pantnagar, Uttarakhand, India, Department of Agronomy, College of Agriculture, GBPUAT, Pantnagar, Uttarakhand, India*

A field experiment was conducted during *kharif* season of 2017 and 2018 at Medicinal Plants Research & Development Centre (MRDC) of G. B. Pant University of Agriculture & Technology Pantnagar, District Udham Singh Nagar (Uttarakhand) to study the effect of different nutrient management approaches on growth attributes viz; plant height, number of branches, leaf to stem ratio and leaf area index of *Kalmegh*. The soil of the experimental site was sandy clay loam in texture having high organic carbon, low available nitrogen, high available phosphorus and medium in exchangeable potassium with slightly alkaline in reaction. The experiment was laid out in Split plot design having 3 main plot treatments and 4 subplot treatments and were replicated 3 times. Among main plot treatments No organics, poultry manure @ 5 t/ha and vermicompost @ 5 t/ha and among subplot treatments, different levels of Nitrogen with same P & K per hectare viz: 0: 50: 50, 50: 50, 75: 50: 50 and 32.5 + 32.5: 50:50 kg NPK per hectare were there. Application of organics and different levels of nitrogen with same P & K kg per hectare had a significant effect on growth attributes viz, plant height, number of branches, leaf to stem ratio and leaf area index etc. at all the stages of crop growth during both the years. Significantly more growth of *kalmegh* plant was recorded in plots treated with vermicompost @ 5 t/ha as compared to poultry manure @ 5 t/ha and no organics. Among sub plot treatments, significantly higher growth trend of the crop was recorded in the plots treated with split application of 75 kg N/ha (half as basal application and half as top dressing at 25 DAT) with same P and K per hectare over 0: 50: 50, 50: 50, 75: 50: 50 kg NPK per hectare.

INTEGRATED FARMING: AN OPPORTUNITY TO CONQUER CLIMATE CHANGE**HITESH MUWAL¹, DWARKI LAL² AND VINOD BHATESHWAR³***Department of Animal Husbandry & Dairying, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi- 221005 (U.P.), India, ³ Department of Animal Husbandry & Dairying, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi- 221005 (U.P.), India*

Fish provides food, income, employment, and trade in fishery products contribute to poverty reduction and national economic growth in many developing nations. Fishery is, threatened by the effects of warming: changes in ocean currents, precipitation that affects lake levels, river flows, increasing storminess, extreme floods and droughts. Fish can provide opportunities to adapt to climate change by, integrating aquaculture and agriculture, which can help farmers to cope with drought while boosting profits and household nutrition. In the present scenario of climate change additional demands for maximizing food production has led to an approach of integrating fish farming with agriculture & fishery. The integration holds a considerable potential for augmenting production of animal protein, generation of employment opportunities in the rural areas and improvement of socio-economic condition of the farmer. Fish farming can be integrated with livestock, poultry, duck, cash crops, paddy fields, horticulture and floriculture. The main objective of the integrated recycling is to utilize the wastes and by-products from one component of the cycle to the other as a feed, fertilizer. Agriculture plays a significant role in fight against climate change: good practices can increase food security, and reduce emissions. Integrated farming can play a crucial to combat climate change. Rural populations are the future of food security and rural poverty reduction. Integration of fisheries with agriculture is the need of the present situation and a very effective way to overcome climate change.

Key words: Integrated, Farming, Fish, Livelihood and Climate change

POPULATION DYNAMICS OF MAJOR INSECT PESTS ON BRINJAL IN RELATION TO WEATHER PARAMETERS**HUMANE A. N. AND SHINDE A. G.***Department of Agricultural Entomology, College of Agriculture, VNMKV, Parbhani - 431 402 (M.H.)*

Brinjal (*Solanum melongena* L.) is a delicate tropical perennial often cultivated as a tender or half-hardy annual in temperate climate. This economically important commercial crop is infested by more than 142 species of insects, 4 species of mites and 3 species of nematode from planting to harvest. Among the various insect pest attacking the eggplant, shoot and fruit borer, stem borer, jassid, leaf hopper, lacewing bug, Aphid, and white fly, were designated as major pests. Seasonal incidence of jassid, whitefly and shoot and fruit borer on brinjal was studied at research farm of the Department of Agricultural Entomology College of Agriculture, VNMKV, Parbhani during *kharif* season of 2017 and found that the activity of both jassid and whitefly was initiated in the second week of April with mean density of 5.21 hoppers and 5.99 whiteflies per plant. It was associated with 33.94 °C and 21.80 °C maximum and minimum temperatures and maximum relative humidity around 75%. The peak activity of these insects was observed during second week of May when the day and night temperatures fluctuated between 25 °C and 35 °C and relative humidity around 65%. The correlation studies between jassid and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

whitefly and different weather parameters revealed no significant effect of ambient weather on the population fluctuations of these insects. Shoot and fruit borer incidence was first observed on brinjal fruits during first week of April with peak activity of 60% in May first week when day and night temperatures varied from 25°C and 35°C and maximum relative humidity around 65%. Correlation studies between % fruit damage by fruit borer and ambient weather revealed a significantly negative relationship with minimum temperature and significantly positive relationship with maximum relative humidity.

KEY WORDS: Brinjal, population dynamics, sucking pests, weather parameters.

DIGITAL AGRICULTURE: PATHWAY TO INCREASING AGRICULTURE PRODUCTIVITY

IVENKATA REDDY* AND T. GOPI KRISHNA

Department of Agriculture Extension, Agricultural College, Bapatla, Acharya N.G. Ranga Agricultural University, Guntur, Lam

Agriculture must become more efficient and sustainable if it is to provide enough food for a growing world population. Given that 68 per cent of India's population is rural and agriculture is the main source of livelihood for 58 per cent of the population, with advancement in technologies especially in the field of information technology, there is need to consider the role of Digital Agriculture in increasing the productivity by efficient and timely management of inputs. Digital Agriculture refers to use of ICT (Information and communication technology) and data ecosystems to support the development and delivery of timely, targeted (localized) information and services to make farming profitable and sustainable (socially, economically and environmentally) while delivering safe, nutritious and affordable food for all. The key components to support the implementation of Digital Agriculture is Spatial (and Temporal) Data Infrastructure (SDI) and low-cost smart phones and tablets to support the bi-directional flow of data and information to rural consumers. Digital technology will be key to increasing agriculture productivity by delivering tailored recommendations to farmers based on crop, planting date, variety sown, real time localized observed weather and projected market prices. These recommendations will be based on advanced big data analytics related to down-scaled daily observed weather conditions that feed into crop growth models to estimate yields, harvest date and potential pest and disease outbreaks to optimize pest control measures. Remote sensing is another big data resource to support the development of derived weather products (radar), improved hydrology and watershed management, soil health, crop coverage and crop health estimates among other application. Agriculture is a data-intense enterprise when one considers soil variability, moisture and nutrient levels, rainfall variability, timing of key operations like planting and harvesting, and market price volatility. Advanced agriculture industries help farmers manage these production and market risks through the application of spatial/temporal data bases that are cloud enabled and integrated through Application Programming Interfaces (APIs). This creates a rich and dynamic data ecosystem that enables advanced analytics to inform farmers of the best economic options to maximize profitability and minimize risk - the two critical variables in farming.

MICROWAVE ASSISTED OIL EXTRACTION OF BLACK SEED (*NIGELLA SATIVAL*)

IFTIKHAR ALAM¹, N.C. SHAHI²

Department of Post-Harvest Process and Food Engineering, GBPUAT, Pantnagar

Nigella sativa L. also known as black cumin or black seed is an annual herbaceous plant belonging to the Ranunculaceae family. *Nigella* seed oil is considered as one of the newer and prospective sources of edible oils that have an important role to play in human nutrition and health. Black seeds are used for edible and medicinal purposes in many countries including India, Egypt and Syria. Mostly, the oil extracted from the black seeds is done by conventional extraction method i.e., pressing but the problem associated with this method is its much time consumption and poor yield. In order to overcome this problem newer technologies of extraction are in process like Microwave assisted extraction and Ultrasound assisted extraction. In this context, a study for microwave-assisted oil extraction from black seed was conducted using three independent variables of three levels each. The best possible combinations of extraction variables was obtained with the full factorial design. The variables were Microwave time (3, 5, 7 min), Microwave power (320, 480, 640 W), and solvent to solid ratio (10:1, 15:1, 20:1). The maximum oil yield of 33.6% was achieved at the microwave power of 480 W, microwave time of 5 minutes and the solvent to solid ratio of 15:1.

Keywords: Black seed, oil extraction, microwave assisted extraction.

EFFECT OF CROP INTENSIFICATION AND ESTABLISHMENT TECHNIQUES ON ECONOMICS OF DIFFERENT CROPPING SYSTEM

INDU BALA SETHI,^{*} ROHITASHV SINGH¹, V.K. SINGH¹, SUMIT CHATURVEDI², AJIT PRATAP SINGH³, DUSHYANT PRABHAKAR⁴ AND JODH PAL SINGH⁵

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

ARS, Navgaon, Alwar (301025,) Department of Agronomy, JRO, Department of soil science³, G.B. Pant University of Agriculture & Technology, Pantnagar, Uttarakhand (263145)

The field experiments were conducted during 2015-16 and 2016-17 at Norman E. Borlaug Crop Research Center, G.B Pant University of Agriculture & Technology, Pantnagar, U.S. Nagar (Uttarakhand) India, to study intensification and establishment techniques of rice-wheat system and influence on economics under irrigated condition. Among various cropping systems the maximum cost involvement was registered in Rice (DSR) Potato Cowpea sequence (₹ 120693 /ha during 2015-16 and ₹ 122066 /ha during 2016-17). The maximum values of gross return (₹ 483007 and ₹ 500302 /ha during 2015-16 and 2016-17, respectively), and net return (₹ 362314 and ₹ 378236 /ha during 2015-16 and 2016-17, respectively) were obtained in [Rice (DSR) Potato Cowpea]. However, the benefit: cost ratio was found to be the highest (3.25 and 3.37) in [Rice (DSR) vegetable pea maize (cob+ fodder)] during 2015-16 and 2016-17, respectively. During 2015-16 the maximum system profitability (1192 ₹/ha/day) was recorded in Rice (DSR) Potato Cowpea sequence, while, during 2016-17, [Maize (Bed) (cob + fodder) + Cowpea (vegetable) (Bed) + Sesbania (Furrow)-2:1:2 - Vegetable pea + Toria-3:1 - Groundnut+Mentha-3:1 (Broad bed furrow 105cm x 30 cm)] recorded the maximum value (1245 ₹/ha/day) being at par with Rice (DSR) Potato Cowpea sequence. The highest crop profitability was recorded in Rice (DSR) Potato Cowpea sequence with 992.64 and 1036.26 ₹/ha/day during 2015-16 and 2016-17, respectively. The highest relative economic efficiency (233.09 % and 241.49 %) was noticed in [Rice (DSR) Potato Cowpea] cropping system during 2015-16 and 2016-17, respectively. Rice (DSR) Potato Cowpea sequence was found economically efficient in overall treatments.

Keywords: intensification, establishment techniques, rice-wheat and economics

MICROWAVE ASSISTED FLUIDIZED BED DRYING OF CAPSICUM: EFFECT ON DRYING KINETICS AND ANTIOXIDANT PROPERTIES

INSHAZAHOOR* AND MOHAMMAD ALI KHAN

Department of Post-Harvest Engineering & Technology, Faculty of Agricultural Sciences, Aligarh Muslim University, Aligarh-202002, India

The experiments were conducted to study the effect of microwave power, inlet air velocity and inlet air temperature on drying characteristics and antioxidant properties of capsicum dried by microwave assisted fluidized bed drying (MAFBD). Samples were prepared by cutting the capsicum to a uniform size (1.5 cm x 1.5 cm x 0.5 cm) to allow power fluidization at different velocities. This was done by carrying out the trials of different sizes at different air velocities to obtain proper fluidization and hence satisfactory results. Capsicum samples were then dried to moisture content of about 6% (db) at different power levels (180 W, 360 W and 540 W), inlet air velocities (15 m/s, 17.5 m/s and 20 m/s) and inlet air temperature (40 °C, 55 °C and 70 °C). Drying time was greatly reduced in MAFBD as compared to fluidized bed drying. The results obtained at the least level of parameters when compared with those obtained at extreme levels, a 50 % reduction in drying time was obtained. The increase in microwave power, inlet air velocity and inlet air temperature enhanced the dehydration of the capsicum cubes. Face centered response surface methodology was applied to obtain regression polynomial models for drying parameters. Design expert 13 was used for the optimization and work plan of the whole experimentation. The quadratic model was found to be significant for drying time and antioxidant properties of capsicum. Keeping the responses like vitamin C content, total phenolic content, total flavonoid content, total carotenoid content and drying time in consideration, the optimum values of microwave power, inlet air velocity and inlet air temperature were 540 W, 20 m/s and 70 °C respectively.

A STUDY ON KNOWLEDGE, ATTITUDE AND ADOPTION BEHAVIOR OF PADDY GROWER IN JAMMU DISTRICT OF J&K STATE

1st IQBAL SINGH, 2nd S.K SINGH¹

Deptt. Of Agriculture Extension R.B.S college Bichpuri Agra (U.P), SMS, KVK, Awagarh, Etah R.B.S college Bichpuri Agra (U.P)

Agriculture is the back bone of Indian economy. To access the Knowledge level, attitude and adoption pattern of Paddy growers. The study was conducted purposively in Marh and R.S Pura block of Jammu District of J&K State due to maximum Paddy growing farmers in these two blocks. A total Nos. of 240 farmers were interviewed by preparing a interview schedule. The result of finding shows that there is a significant and positive correlation regarding seed technology, usage of fertilizer application plant protection technology. The attitude of the farmers were also found significant regarding these technology.

Key words:- Knowledge ,Attitude, Behavior ,Paddy farmers

THE QUALITATIVE PHYTOCHEMICAL ANALYSIS OF FOUR MEDICINAL PLANTS (*ALLIUM SATIVUM*, *CURCUMA LONGA*, *TINOSPORA CORDIFOLIA* AND *WITHANIA SOMNIFERA*)**IQRANAZIR¹* AND RIKHI. S. CHAUHAN²**

¹Department of Aquaculture, College of Fisheries, G. B. Pant University of Agriculture & Technology, Pantnagar -263145 (Uttarakhand), INDIA, ²Department of Aquaculture, College of Fisheries, G. B. Pant University of Agriculture & Technology, Pantnagar -263145 (Uttarakhand), INDIA

The phytochemical analysis of the plants is very important commercially and has great interest in pharmaceutical companies for the production of the new drugs for curing of various diseases. Phytochemicals have two categories i.e., primary and secondary constituents. Primary constituents have chlorophyll, proteins sugar and amino acids. Secondary constituents contain terpenoids and alkaloids. Medicinal plants have antifungal, antibacterial and anti-inflammation activities. The present study involves the qualitative phytochemical analysis of four different medicinal plants: *Allium sativum*, *Curcuma longa*, *Tinospora cordifolia* and *Withania somnifera* that are locally available in pantnagar, region of Uttarakhand. The aqueous and ethanolic extract samples were used for the phytochemical analysis to find out the phytochemical constituents in the plants. Garlic, turmeric, guduchi and ashwagandha are very renowned medicinal plant for its versatile pharmaceutical properties. For finding several compounds qualitative phytochemical analysis is very important. Two different solvents viz; water and ethanol were used to obtain extracts. These extracts were used for qualitative preliminary phytochemical analysis using standard chemical tests. Data indicates the presence of flavonoids, alkaloids, proteins, phenolic compounds, cardiac glycosides and tannins.

Key words: Ethanolic, phytochemicals, *Tinospora cordifolia*, *Curcuma longa*, flavonoids.

MOLECULAR METHODS FOR DETECTION OF *ALBUGO CANDIDA* (PERS.) KUNZE CAUSING WHITE RUST OF RAPESEED-MUSTARD**IRFAN KHAN^{*1} AND IQBAL AHMED²**

¹Department of Plant Pathology, ²Department of Plant Breeding and Genetics, Rajasthan College of Agriculture, MPUA&T, Udaipur-313301 (India)

Albugo candida, biotrophic, the oomycete pathogen, causes white rust disease of rapeseed-mustard globally. The characteristic symptoms of the disease are formation of white to cream-coloured pustules on leaves, stems, and inflorescences, sometime staghead galls formation takes place as the result of inflorescence infection. The pathogen causes significant losses in oilseed brassicas. A prerequisite to the control of diseases is detection and proper identification of the causal organism. Traditional methods are some limitation viz. they are the relatively slow process, often requiring the skilled person to reliable identification of the pathogen. Recently, the potential of molecular methods for the detection of plant pathogen has been recognized. Molecular techniques based on DNA analysis are very useful for pathogen detection because they are highly specific and sensitive. Internal transcribed spacer (ITS) based primers are used for routine detection of *A. candida*. Real-time PCR is the most rapid method, reproducible and accurate to detect the target pathogen in the plant. The proteomic study is currently using by the researcher to explore the molecular mechanisms of defence responses by *Brassica juncea*. PCR-based marker, such as random amplified polymorphic DNA (RAPD), has an advantage that it does not require prior information about genomic sequences. RAPD markers are usually dominant because polymorphisms are detected as the presence or absence of bands. RAPDs are used successfully as genetic markers in genetic studies of *A. candida*. Amplified fragment length polymorphism (AFLP) markers also have been used for genetic analysis and genome mapping of this devastating pathogen.

EVALUATION OF PROMISING CHEMICALS TO ENHANCE FLOWERING, FRUITING AND SHELF LIFE OF LITCHI (*LITCHI CHINENSIS* SONN.)**J.C. CHANDOLA¹, SATISH CHAND¹, SHWETA KUMARI², RANJAN SRIVASTAVA¹, RATNA RAI¹, D.S. MISHRA³ AND M.K. BHATT⁴**

¹Department of Horticulture, College of Agriculture, G.B. Pant University of Agriculture and Technology, Pantnagar (U.S. Nagar), Uttarakhand, India, ²Department of Horticulture (Fruit & Fruit Technology), Bihar Agricultural University, Sabour-813210, ³Senior Scientist (Fruit Science), Regional station-CHES, Vejalpur, Godhra (Gujarat), ⁴Department of Horticulture, College of Agriculture, G.B. Pant University of Agriculture and Technology, Pantnagar (U.S. Nagar), Uttarakhand, India

The present investigation entitled "Evaluation of promising chemicals to enhance flowering, fruiting and shelf life of litchi (*Litchi chinensis* Sonn.)" was conducted at Horticultural Research Centre, Patharchatta, Department of Horticulture, G.B. Pant University of Agriculture and Technology, Pantnagar, Udham Singh Nagar (Uttarakhand) in the year 2013 to 2015. The experiment was conducted to determine the effect of chemicals viz., KNO₃ (1%), K₂HPO₄ (1%), KH₂PO₄ (1%), K₂HPO₄ (2%), KH₂PO₄ (2%), K₂HPO₄ (1%) + KNO₃

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

(1%), KH_2PO_4 (1%) + KNO_3 (1%), Ethrel (400 ppm) and water which were sprayed thrice at monthly interval from October to December. There were nine treatments which replicated thrice in randomized block design. The results obtained indicate that foliar application of KNO_3 (1%) was effective for improving number of vegetative flushes (4.83), sex ratio (1.54 to 1.86%), number of shoots showing panicle emergence (90%), fruit breadth (3.82 cm), fruit weight (21.93g), fruit retention (28.33%), shelf life (5.8 days) and significantly reduced fruit drop (45.37%), total acidity (0.33%) of fruits in litchi. On the other hand, Ethrel (400 ppm) was effective for early panicle initiation *i.e.*, on 3rd February, fruit set (2nd April), increasing fruit length (3.93cm), early fruit harvest (10th June and 5th June during the years 2014 and 2015), fruit yield (105.42 kg/tree), TSS (20.70⁰B), total sugars (13.19%) along with increasing higher number of fruits in the extra-large grade (82.06%). Therefore, it could be concluded that KNO_3 (1%) and Ethrel (400 ppm) sprays can be recommended for enhancing quality and yield characters of litchi fruits cv. Rose Scented.

EFFECT OF DIFFERENT ROOTSTOCK-SCION COMBINATIONS ON VEGETATIVE GROWTH OF PEAR UNDER NURSERY LEVEL**J PRATHORE, AMIT KUMAR, M K SHARMA, ANIL SHARMA AND TSERING DOLKAR***Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K)*

A field study on "Effect of vegetative growth on different rootstock-scion combinations in Pear" was carried out at Experimental Farm, Division of Fruit Science, Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar, Srinagar (J&K) during 2017. Treatments consisted of four levels of scion cultivars (Carmen, Abate Fetel, William Bartlett and Chinese Sandy Pear) and five levels of rootstocks (Quince C, BA-29, Quince, Kainth and Pear Sucker) constituting twenty treatment combinations. It was found that earliest bud burst date (14th April) was recorded in Chinese Sandy Pear/Quince, Highest grafting success per cent (96.67 %) was recorded in Carmen/Quince C, Abate Fetel/Quince C, Chinese Sandy Pear/Quince C, Abate Fetel/BA-29 and Chinese Sandy Pear/Quince, Highest initial stock girth was observed (34.29 mm) in Chinese Sandy Pear/Quince, Highest initial scion girth was observed (38.51 mm) in William Bartlett/Kainth, Maximum initial stock-scion ratio was recorded in Chinese Sandy Pear/Quince (0.90), Final scion girth was recorded maximum in Carmen/Quince (6.18), Maximum plant height (132.15 cm) was recorded in Chinese Sandy Pear/Pear sucker whereas minimum plant height (98.16 cm) was recorded in Carmen/Quince. Maximum number of branches per plant was recorded in Chinese Sandy Pear/Pear sucker (3.55), Maximum leaf area was recorded in Chinese Sandy Pear/BA 29 (23.46 cm²), Maximum number of leaves per plant (91.93) was recorded in Chinese Sandy Pear/Quince C. Maximum specific leaf area (44.81 cm²/g) was observed in Chinese Sandy Pear/Kainth, Maximum internodal length was recorded in William Bartlett/Pear sucker (2.31 cm), Maximum saleable plants were achieved in William Bartlett/Quince (86.33 %). On the basis of foregoing summery, the results may be concluded as follow: effect of vegetative growth on different rootstock-scion combinations in pear in the present study. Among the different rootstock-scion combinations Quince C performed better with respect to all the studied parameters followed by Quince.

ECONOMICS OF BUFFALO MILK PRODUCTION IN DIFFERENT SEASONS AND ITS CONSTRAINTS IN FAIZABAD DISTRICT OF UTTAR PRADESH**J.N. YADAV¹, R. A. SINGH², HARENDER YADAV³, V.P.S. YADAV⁴, RAJENDER KUMAR⁵***Agri. Economics, NDUAT, Faizabad, Scientist - B, CTR & TI, Piska Nagri, Ranchi, Jharkhand Principal Ext. Specialist/ Professor, KVK, Faridabad.*

The livestock sector considered to be a major enterprise in agriculture sector. It is increasingly recognized that dairying could play a more constructive role in promoting rural welfare and reducing poverty. Besides, dung is an important input as organic manure for crop production and also widely used as fuel in rural areas. Keeping in view the importance of livestock among farming community a study was carried out in five villages of Faizabad district of Uttar Pradesh. For the study sixty buffalo milk producing households were selected randomly. The highest feeding cost was worked out in summer followed by winter and rainy seasons., it was Rs. 64.70, 63.96 and 50.32 in marginal herd size group ; Rs. 60.13, 58.74 and 47.46 in small herd size group and Rs. 55.82, 45.88 and 44.58 in medium herd size group during winter, summer and rainy seasons respectively. The net maintenance cost of per milch buffalo per day was estimated by deducting the income from dung from the total maintenance cost. In winter, summer and rainy seasons, it was Rs. 101.85, 98.95 & 91.85 on marginal, Rs. 96.07, 92.94 & 86.60 on small and Rs. 88.14, 85.44 & 80.30, respectively on medium herd size groups. The net profit of milk production per milch buffalo per day was Rs. 70.28, 69.34 & 86.41 on marginal, Rs. 85.98, 83.84 & 104.24 on small, Rs. 105.77, 103.42 & 121.73 on medium herd size groups in summer, winter and rainy seasons respectively. The cost benefit ratio per milch buffalo per day was reported 1.63, 1.64 & 1.86 during winter, summer and rainy seasons, respectively on marginal herd size groups. The same trend was found in small and medium herd size groups. The results highlighted that the women participation in milk production was higher in feeding, compost making, milking, as compared to other practices. As constraints in dairying farming were studied, these were reported as low price of milk, inadequate knowledge about balanced feeding, lack of vaccination at appropriate time, lack of dairy

“MITIGATION OF SPOT BLOTCH OF BARLEY (*HORDEUM VULGARE* L.) THROUGH AGRICULTURAL PRACTICES FOR MAXIMIZATION OF THE SEED QUALITY.”

MAJOR ADVISOR: J. P. SRIVASTAVA

Department Of Genetics And Plant Breeding, N.d. University Of Agriculture & Technology, Kumarganj, Faizabad-224 229 (U.P.) India

Barley (*Hordeum vulgare* L.) belonging to the family Poaceae, is an annual monocotyledonous herb, tribe *Triticeae*. Barley is evolutionarily closely related to two other small-seeded cereal species, wheat and rye. India has about 7.57 lakh ha area with production of 14.72 lakh tonnes and productivity of 19.44 q/ha. In UP, barley occupied an area of 2.86 lakh ha with a total production of 6.38 lakh tonnes with productivity of 22.25 q/ha. Uttar Pradesh alone contributed more than one fourth of India's total production of barley during 2016-17. We are still below the world average in its productivity level as it is cultivated under minimum input management conditions. The demand for the malt barley from industry is on the rise which is presently nearly 18-20 per cent of the total barley production of the country. A good quality seed should maintain the viability and germination till the next sowing season. Germination of quality seed lot should be high for obtaining the desired crop stand in the field. Vigour of quality seed should be high as the vigorous seeds will stand better in the field in adverse condition. All these qualities of seeds are affected by various factors including various seed borne pathogens. Spot blotch disease caused by the fungus *Bipolaris sorokiniana* (teleomorph *Cochliobolus sativus*) is one of the most important fungal disease of barley. Many factors including climate conditions (Rainfall, temperature and humidity) and agricultural practices influence the development and spread of disease and thus affect the seed crop. Considering quantum of losses, the investigations on management of spot blotch, for maximizing the seed quality, experiment were conducted at CRS, Masodha and Students' Instructional Farm and Seed Pathology Laboratory at Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during 2016-17 and 2017-18. Effect of date of sowing, organic and chemical amendments on disease severity was quantified during the present investigation. Effect of different nitrogen levels and treatment with Plant Growth Promoting Rhizobacteria on disease severity was studied. Also the disease management through seed treatment and fungicidal foliar sprays was tried to recommend a management schedule for bring down the disease severity, maximize seed yield and its quality. Minimum seed infection of *Bipolaris sorokiniana* (5.5%) was recorded through the crop sown in mid-November with recommended dose of fertilizers + FYM @ 5t/ha plus paddy straw mulching followed by two sprays of zinc sulphate and KCl. This treatment resulted in maximize the viability, germination, seedling length and vigour index also. Nitrogen @30 Kg/ha with seed treatment of Azatobacter plus PSB was found best for minimizing the disease and optimizing the seed quality attributes. Seed treatment with Vitavax Power @ 2.0 g/kg seed and two foliar sprays of Propiconazole @ 0.10% (first at tillering and second after 15 days) in minimizing the spot blotch severity with highest seed quality traits. This treatment also resulted in 40.64 per cent yield increase as compared to untreated and water sprayed plot.

MARKER ASSISTED BREEDING IN IMPROVING WHEAT FOR CLIMATE RESILIENCE

J.P. JAISWAL¹, ANUPAMA SINGH¹, SAURABH BADONI, DEEPSHIKHA², EKHLAQUE AHMAD³, R.P. GANGWAR¹, DEVENDER SHARMA¹, N.C. GAHTYARI¹ AND PAWAN K. SINGH⁴

¹Department of Genetics & Plant Breeding and ²Department of Plant Pathology, G.B. Pant University of Agriculture & Technology, Pantnagar- 263145, India; ³Department of Genetics & Plant Breeding, BAU, Ranchi, ⁴International Centre for Maize and Wheat Improvement (CIMMYT), El Batan, Texcoco 56237, MEXICO.

Ever increasing threats of climate change to crop production and food security are being currently discussed globally. Wheat (*Triticum aestivum* L.) is one of the most important food crops worldwide, occupying largest cultivated area, and supplying 40% of food globally and 25% of calories for the developing world. Hence increase in its production and productivity is very much desired to meet the demand of ever increasing population. Climate change and global warming have profound effect on resurgence of new races/pathotypes of different disease causing organism. It has also been proved that yield potential of high yielding varieties is seldom realized due to disease pressure. Therefore, development of disease resistance varieties has been one of the important goals in crop improvement. Wheat is affected by several diseases, but rusts caused by *Puccinia* spp. are the most important. The impact of rust on yield reduction in wheat ranges from 10% under moderate and 65% under intense epidemics. In India too, the losses caused by rust infection are around 40% under conducive environment. Yellow rust epidemic in 2010-11 and breakdown of Yr9 resistance in mega wheat variety PBW 343 and susceptibility of other high yielding varieties like UP 2338, DBW 17, HD 2967 after a small period of their release warrants attention to develop wheat varieties with durable rust resistance. Five new pathotypes, namely, 110S119, 238S119, 110S84, 110S247 and 46S117 of stripe rust (*Puccinia striiformis*) reported in 2014 demands serious attention towards preparedness to fight against potential threat of this devastating pathogen. Due to change in climate, the severity of spot blotch (*Bipolaris sorokiniana*) incidence is increasing in North

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Western Plains Zone (NWPZ) of India where leaf and stripe rust, and powdery mildew were major diseases. Hence exotic germplasm obtained from CIMMYT, Mexico were screened under epiphytotic conditions and resistance lines were identified using gene linked markers. Considering the importance of yellow rust in Northern Hills Zone (NHZ) and yellow as well as brown rusts in North Western Plains Zone (NWPZ), two major yellow rust resistance genes, Yr10 and Yr15 and brown resistance genes Lr19/S25, Lr24/Sr24 and Lr34/Yr18 from the donor genotypes were mobilized in popular cultivars and elite genotypes. It is envisaged that marker-assisted deployment of major genes along with APR genes will confer durable rust resistance in wheat.

WEED MANAGEMENT IN KHARIF GREENGRAM (*VIGNA RADIATA* L.) UNDER MIDDLE GUJARAT CONDITIONS**J.P. PATIL*, S.V. AHIRE AND P.K. SURYAWANSHI**

B. A. College of agriculture, Anand agricultural university, Anand-388 110, College of Agriculture, Malegaon camp, Nashik (Maharashtra)

A field experiment was conducted during *kharif* season of the year 2010 at the farm of DWSR-Anand Centre, B. A. College of Agriculture, Anand Agricultural University, Anand (Gujarat). The twelve weed control treatments viz., pendimethalin @ 1000 g ha⁻¹ (PE) (T₁), pendimethalin @ 1000 g ha⁻¹ PE *fb* hand weeding at 30 days after sowing (T₂), quizalofop-ethyl @ 50 g ha⁻¹ (POE) (T₃), quizalofop-ethyl @ 50 g ha⁻¹ POE *fb* HW at 30 DAS (T₄), quizalofop-ethyl @ 100 g ha⁻¹ POE (T₅), quizalofop-ethyl @ 100 g ha⁻¹ POE *fb* HW at 30 DAS (T₆), imazethapyr @ 50 g ha⁻¹ POE (T₇), imazethapyr @ 50 g ha⁻¹ POE *fb* HW at 30 DAS (T₈), imazethapyr @ 100 g ha⁻¹ POE (T₉), imazethapyr @ 100 g ha⁻¹ POE *fb* HW at 30 DAS (T₁₀), Interculture and HW at 20 & 40 DAS (T₁₁) and weedy check (T₁₂) were studied in randomized block design with four replications. At 25 and 50 DAS, significantly lower weed population, dry weight of monocot and dicot weeds were recorded in interculturing and hand weeding carried out at 20 & 40 DAS which were at par with the treatment of quizalofop-ethyl @ 50 g ha⁻¹ POE, quizalofop-ethyl @ 50 g ha⁻¹ POE *fb* HW at 30 DAS, quizalofop-ethyl @ 100 g ha⁻¹ POE and quizalofop-ethyl @ 100 g ha⁻¹ POE *fb* HW at 30 DAS, in case of monocot weeds and imazethapyr @ 100 g ha⁻¹ POE and imazethapyr @ 100 g ha⁻¹ POE *fb* HW at 30 DAS in dicot weeds. Maximum weed control efficiency recorded in interculturing and hand weeding treatments at 25, 50 DAS and at harvest. The treatment of interculturing and hand weeding carried out at 20 & 40 DAS recorded significantly higher plant height at 30 DAS and at harvest, dry weight of *Rhizobium* nodule, no. of branches plant⁻¹, no. of pods plant⁻¹, length of pod, test weight, seed and haulm yield.

STUDY ON DAIRY HUSBANDRY PRACTICES IN SAHARANPUR DISTRICT**JAGDEEP KUMAR, RAJBIR SINGH, RAJKUMAR, DEEPAK KUMAR & SOMNATH**

Department of Animal Husbandry, College of Veterinary and Animal Sciences, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut, Uttar Pradesh, India

The present study was carried out in Saharanpur district of Uttar Pradesh through 200 dairy farmers to measure the study on dairy husbandry practices in Saharanpur district. The study showed that majority of the respondents 80.50 percent kept their animals in *pucca* houses, whereas 78.00 per cent kept in close house type. 89.50 percent respondents provided manger but 84.50 percent had *pucca* type manger. 67.00 percent respondents cultivate green fodder crops and 84.00 and 63.50 percent respondents fed green non-leguminous fodder and shedha grass, respectively. Paddy straw was major ingredient 89.00 percent used as dry fodder, 66.50 percent respondents fed homemade + compound cattle feed as concentrates to their milking animals, Bred their animals by artificial insemination 79.50 percent between 12-18 hours after heat detection 85.00 percent, 74.00 percent respondents bred their animals after 2 to 3 months of calving and 80.50 percent respondents followed the pregnancy diagnosis. 71.50 percent respondents followed treatment of anestrous/repeaters in their dairy animals. 69.50 percent respondent using knuckling methods of milking. 83.50 percent respondents followed stripping at the end of milking and all the respondents did not wipe the udder and teats just after milking. 64.50 percent respondents allowed calves for suckling before milking. 95.50 percent respondents practiced regular vaccination of their animals against FMD and HS disease. 62.00 percent respondents practiced deworming of their dairy animals regularly, followed various practices for control of ecto-parasites 81.00 percent. 90.50 percent respondents followed practice to feed colostrum to new born calves but only 52.50 percent respondents fed colostrum to new born calves within one hour of birth. 68.50 percent respondents followed weaning practices at the age of three months. Dairy farmers should keep farm records of their animals which will help them in reproductive management, health management and selection of good animals for the future generation.

Key Words: Housing, Feeding, Breeding, Health Care and Milking management.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

ROOT BORDER CELLS AND SECRETIONS AS CRITICAL ELEMENTS IN PLANT HOST DEFENSE

JAGMOHAN SINGH, RASHMI AGGARWAL, M.S. GURJAR AND M.S. SAHARAN

Division of Plant Pathology, ICAR- Indian Agricultural Research Institute, New Delhi-110012

The adaptation of plants to land ecosystems involves complex rhizosphere interactions between organic matter and microbial communities. Border cells (BC) constitute the first living boundary in plant-soil ecosystems and play an important role in environmental sensing and signaling in response to different biotic and abiotic conditions. Border cells and border-like cells are released from the root tip as individual cells and small aggregates, or as a group of attached cells. These are viable components of the root system that play a key role in controlling root interaction with living microbes of the rhizosphere. As their separation from root tip proceeds, the cells synthesize and secrete a hydrated mucilage that contains polysaccharides, secondary metabolites, antimicrobial proteins and extracellular DNA (exDNA). This exDNA-based matrix seems to function in root defense in a way similar to that of recently characterized neutrophil extracellular traps (NETs) in mammalian cells. Both cell types export a complex of extracellular DNA (exDNA) and antimicrobial proteins that neutralize threats by trapping pathogens and thereby preventing invasion of host tissues. Extracellular DNases (exDNases) of pathogens promote virulence and systemic spread of the microbes. In plants, adding DNase I to root tips eliminates border cell extracellular traps and abolishes root tip resistance to infection. Mutation of genes encoding exDNase activity in plant-pathogenic bacteria (*Ralstonia solanacearum*) results in reduced virulence. Engineering the rhizosphere to increase plant resistance to pathogens could be achieved through breeding, which potentially selects for novel root and root border cells' architecture and function.

IMPROVING SOIL HEALTH THROUGH VERMICOMPOST IN AGRICULTURE

JAGRUTISAHU¹ AND LICON KUMARACHARYA²

M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Plant Pathology, Institute of Agricultural Science, Siksha O Anusandhan University, Bhubaneswar, Odisha

Vermicomposting is an effective means of composting the decomposable organic wastes using earthworms naturally present in the soil. Vermicomposting is a mixture of worm casts enriched with macro and micronutrients (N, P, K, Mn, Fe, Mo, B, Cu and Zn.), some growth regulating substances (such as gibberellins and auxins) and useful micro flora (*Azospirillum*, *Actinomyces* and *Phosphobacillus*) etc. which naturally helps in improvement of soil fertility or soil quality. Excessive use of chemical fertilizers in agricultural land causes large number of environmental problems. Ignorance in terms of manure and fertilizer application with respect to the fertility status is one of the major factors leading to the low productivity of the crops. The return, therefore, is not a constant and reliable factor for the farmers resulting in their low financial status. In order to evaluate the requirement of balanced fertilizers to be applied in the field analysis of soil for available nutrients is quite necessary. In this background, use of organic manure such as vermicompost may improve quality of agricultural products and enhancement of soil quality by organic amendment especially vermicomposting is becoming increasingly popular among farmers as a source of soil fertility and also as a source of income generation.

Keywords: Vermicomposting, soil and fertilizer.

ROLE OF DISEASE FORECASTING IN PLANT DISEASE MANAGEMENT

JAI PRAKASH KANNAUJIA, GOPAL SINGH, SATPAL SINGH, ANUPAM KUMAR AND SURANDRA KUMAR

Department of Plant Pathology, SVPUA&T, Meerut, UP, India.

Forecasting of plant diseases means predicting for the occurrence of plant disease in a specified area ahead of time, so that suitable control measures can be undertaken in advance to avoid losses. Forecasting involves all activities in ascertaining and notifying the farmers in a community that the conditions are sufficiently favourable for certain diseases, that the application of control measures will result in economic gains or that the disease expected is unlikely to be enough to justify the expenditure of time, energy and money to be utilized for its control. Disease forecasting are mainly of two types, positive forecast employs need based chemical sprays, provides adequate protection to crop and reduce damage to environment. Negative forecast avoids unnecessary chemical sprays, no risk to the crop health and no disruption of environment. To develop a plant disease forecast, one must take into account several characteristics of the particular pathogen, host, and of course, environment. In general, for most monocyclic diseases (such as root rot of peas) and for a few polycyclic diseases that may have a large amount of initial inoculums (such as apple scab), disease development may be predicted by assessing the amount of the initial inoculums. For diseases in which both the amount of initial inoculums and the number of disease cycles are large, both factors must be assessed for the accurate prediction of disease epidemics. Such assessments, however, are often difficult or impossible, and, despite considerable improvements in equipment and methods, assessments of initial inoculums or rapidity of infection cycles are seldom accurate. Plant pathologists should write programs that allow the simulation of epidemics of the most important plant diseases. One of the first computer simulation programs, called EPIDEM, was written in 1969 and resulted from modelling each stage of the life cycle of a pathogen as a function of the environment. EPIDEM was designed to simulate epidemics of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

early blight of tomato and potato caused by the fungus *Alternaria solani*. Subsequently, computer simulators were written for Cercospora blight of celery (CERCOS), for *Mycosphaerella* blight of chrysanthemums (MYCOS), for southern corn leaf blight caused by *Cochliobolus* (*Helminthosporium maydis*) (EPICORN), and for apple scab caused by *Venturia inaequalis* (EPIVEN). A more general and more flexible plant disease simulator, called EPIDEMIC, was written primarily for the stripe rust of wheat but could be modified easily for other host pathogen systems. Computer simulation programs are now available for numerous plant diseases.

THE ROLE OF AGROFORESTRY IN THE VIEW OF AGRICULTURE & ENVIRONMENT

***JAIVEER SINGH DHEWA AND YOGESH KUMAR AGARWAL**

Department of Agroforestry, SHUATS Allahabad, UP, India -211007

Advent of "Climate Change" has put forth more emphasis on agroforestry. Agroforestry is economically and ecologically viable option for producing more crop yields along with environmental amelioration and resource conservation. Agroforestry provides robustness against extreme and erratic weather shelter against storms soil water retention capacity of the soil and add organic matter to the soil. On the other hand it acts as a major carbon harvester. Agriculture is well known as a significant contributor to global greenhouse gas emissions, but emerging practices in land management have the potential to curtail these emissions and reverse much of the ecological and climate harm caused by overly intensive systems. One such practice, cultivation and conservation of trees in agricultural practices, or agroforestry, is an important climate-smart solution with many important co-benefits. Trees can provide quality timber as well as fuel while the farmer can continue to raise livestock or grow crops. It also contributes to the reduction of greenhouse gas emissions from farms. Agroforestry is one of the best practices for sustainable agriculture. In this regard pulse crops play a vital role and provide a rich source of protein. It is, therefore, agroforestry is indeed an integral part of environment & agriculture. But the benefits are significant.

Key Words: Agroforestry, Economic, Farmer and Environment.

TO STUDY THE NUTRITION LEVEL ON SESAMUM (*SESAMUM INDICUM* L.) VARIETIES UNDER RAINFED CONDITION

JANKI PRASAD*, SHASHANK SRIVASTAV*, C.B. VERMA GIRJESH KUMAR**

Department of Crop Physiology, Chandra Shekhar Azad University of Agriculture and Technology Kanpur

An experiment was conducted during kharif 2017, (August to October) in micro plot at Department of Crop Physiology Chandra Shekhar Azad University of Agriculture & Technology Kanpur, Uttar Pradesh, (India). Complete Randomized Block Design was used in trial aimed with to study the effect of Nitrogen, Phosphorus, Potassium, Sulphur and Farm Yard Manure used in the experiment were 40:20:20:20 kg/ha and 2.5 t/ha respectively. Significantly increased growth yield and quality of sesamum varieties Shekhar (V_1), Pragati (V_2), and Tarun (V_3) and treatment as control (NPK) T_1 , NPK+S (T_2), NPK+FYM (T_3) and NPK+S+FYM@ 40:20:20:20 kg /ha and 2.5 t/ha. (T_4). Result revealed that the application of T_4 (Nitrogen, Phosphorus, Potassium, Sulphur and Farm Yard Manure) and variety Tarun over all best response in all observation like as used in the experiment were Significantly increased seed yield (q/ha.), Chlorophyll intensity (%), RWC (%), plant height (cm), Branches/plant were significantly enhanced in comparison to control (NPK).

RESPONSE OF SESAMUM (*SESAMUM INDICUM* L.) CULTIVARS UNDER DIFFERENT VARIETIES AND LEVEL OF DOSE ON FERTILIZER UNDER RAINFED CONDITION

JANKI PRASAD, C.B. VERMA

Department Of Crop Physiology

P.N. Nigam (Directorate of Seed and Farm), Chandra Shekhar Azad University of Agriculture and Technology Kanpur

A trial was conducted during kharif 2017, in micro plot at Department of Crop Physiology Chandra Shekhar Azad University of Agriculture & Technology Kanpur. To study the effect of Nitrogen, Phosphorus, Potassium, Sulphur and Farm Yard Manure used in the experiment were 40:20:20:20 kg/ha and 2.5 t/ha respectively. BIOLOGICAL CONTROL OF PLANT PARASITIC NEMATODES.

JASKARAN SINGH; SHASHANK MISHRA, AMIT KUMAR YADAV, ABHISHEK KUMAR AND SONU KATIYAR

Department of Plant Pathology, SVPUA&T, Meerut- 250110, UP, India

An environmental and health concerned over the use of pesticide have increase the need for developing alternative measures to control plant Pathogen. Among plant Pathogen, nematodes are an important plant parasites causing considerable direct and indirect loss to the plant. Majority of plant parasitic nematode are soil borne plant pathogens causing damage to root system of the plant. Some of the nematodes are foliar nematode but they also need the soil for completely their life cycle. The number of bio agent such as Fungi, Bacteria, Predatory nematode, Mites, Collembola, Turbellarians are organism which play an important role in the management of plant parasitic nematodes. Nematophagous fungi, a natural enemy of nematodes, have received major attention in biological control of plant-parasitic nematodes. This is due to their specific ability to capture and kill nematodes. Nematophagous fungi are divided into four groups according to their mode of action against nematodes, several fungi such as *Pochonia chlamydosporia* and *Paecilomyces lilacinus* have been developed as commercial biological nematocides. Bacterial parasites are mainly *Pasteuria penetrans*, *Bacillus thuringiensis* and *Streptomyces avermitilis*. Among These bacteria which have been most intensively studied in connection with nematodes, only *P. penetrans* is a true parasite. Mites exhibit density dependent traits of effective and specific predators. Collembola, feeding of plant parasitic nematodes has been reported by various investigators. Turbellarians are soil inhabiting, carnivorous, flatworms that feed on nematodes and other soil organisms. Predacious nematodes constitute a large portion of the biomass in some soils; their role as bio-control agents of plant-parasitic nematode is not well known. Many genera of the nematode i.e., *Mononchida*, *Dorylaimida* and *Diplogasteroidea* are largely considered as predacious nematodes. These bio agents may be useful in management of plant parasitic nematodes which can protect the environment by reducing the parasitic nematodes.

CONSERVATION OF NATURAL RESOURCES THROUGH EFFECTIVE UTILISATION OF AGRICULTURAL WASTE

JASMINE GUNTHA¹ AND JHUNILATA BHUYAN²

M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Home Science, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Agricultural wastes are defined as the residues from the growing and processing of raw agricultural products such as fruits, vegetables, meat, poultry, dairy products, and crops. They are the non-product outputs of production and processing of agricultural products that may contain material that can benefit man but whose economic values are less than the cost of collection, transportation, and processing for beneficial use. Their composition will depend on the system and type of agricultural activities and they can be in the form of liquids, slurries, or solids. Agricultural waste is the material obtained due to crop production or from plant growth. In the past this biomass and agricultural waste were either burnt or naturally converted into organic fertilizer under favourable condition. But now in these days biomass produced from agricultural waste are used to generate energy because it carries great potential to convert into energy. Since the biomass is available throughout the world in abundant quantity so it is necessary to use alternate energy resources to fulfill our needs of energy consumption. The effective utilization of agricultural waste is a good option to convert these wastes in energy. For this efforts have been made and many more are under way, it requires guidelines concerning the utilization of agricultural biomass for energy purposes and optimal production. Production of energy from biomass can provide farmers with new prospects and possibilities to diversify agricultural activities.

Keywords: Agricultural waste, utilization and energy.

EFFECT OF METEOROLOGICAL PARAMETERS ON CROP RESPONSE

JATINDER KAUR¹, SHIVANI KOTHIYAL² AND AARADHANACHILWAL³

^{1,2}Department of Climate Change and Agricultural Meteorology, Punjab Agricultural University, Ludhiana 141004, Punjab,

³Department of Agronomy, Punjab Agricultural University, Ludhiana 141004, Punjab

Various meteorological factors like light, temperature, carbon dioxide and moisture affect the crop crucially. However, the levels of these climate inputs, particularly rainfall, vary between locations and years, in part due to climate variability. Temperature and water supply also vary over the long-term, including in response to climate change, with major implications for crop production, and the livelihood of crop producers. Crop management is therefore very much about managing climate risk so as to have financially viable and sustainable agricultural systems. Climate and management also impact on the spread of weeds, pests and diseases, which in turn affects crop yields, harvest and producer's cost and return. These climatic effects on crop production around the world impact on global trade, with implications for net exporters, net importers and consumers, as well as for national and global food security. Climate variability and changes in the frequency of extreme events are important for yield, its stability and quality. In this context, threshold temperatures for

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

crop processes are found not to differ greatly for different crops and are important to define for the major food crops, to assist climate modellers predict the occurrence of crop critical temperatures and their temporal resolution. The rate of growth of roots, stem and leaves depends on the rate of photosynthesis, which in turn depends on light, temperature, moisture and carbon dioxide. Temperature and day length also determine when plants produce leaves, stems and flowers, and consequently the filling of grain or the expansion of fruit. The yield of grain crops depends on grain number and grain weight at harvest, which in turn depends on biomass at anthesis and the availability of moisture post-anthesis. Thus the different meteorological parameters and their increase/decrease affect the crop and its final response/yield accordingly.

Keywords: climate risk, temporal resolution, critical temperatures, day length

DOUBLING THE FARMERS INCOME THROUGH INNOVATIVE PROTECTED HORTICULTURE

JAYASHRI BARCCHIYA*, DIKSHA MANAWARE², NAKUL RANGARE³,

^{1,2,3} *Department of Horticulture, JNKVV, Jabalpur, MP*

Protected horticulture is one of the most promising areas of horticulture in the new age. It is an upcoming and alternative production system involving high-tech and intensive practices mainly for urban and pre-urban areas. Being a different, distinct and new area involving vast multidisciplinary aspects of agriculture, establishing scope of protected horticulture would be of great help to generate appropriate human resources and technologies including soilless cultivation, hydroponics, aeroponics, vertical vegetable production, riverbed cultivation, mulching, mechanization and maintenance of polyhouse/structure, vegetable/fruit grafting, container farming, off season vegetable and flower nurseries, off season vegetables, year round cultivation of vegetables and organic protected horticulture. Protected horticulture generate employment and income through involving youth as well as farmers to grow, process and market horticulture produce using protected cultivation technologies. Farmers are gradually adopting different protected structures to combat the climatic vagaries and emerging challenges in vegetable production. The technology of protected farming mainly of vegetables and flowers is most suited to promote much needed peri-urban and urban agriculture being useful to both small-scale and large-scale farmers.

EFFECT OF GUAVA LEAVES EXTRACT TREATMENT ON COTTON

ZEBAJAMAL¹ AND VIVEK SINGH²

¹ *P.h.d Research Scholar and* ² *Associate Professor, Dept. of Textile and Apparel Designing, COHS, CCSHAU, Hisar*

Guava leaves extract treatment was prepared and applied on cotton fabric. To find out the efficiency of Guava leaves extract treatment physical properties of controlled, treated and washed samples were compared. Extraction of Guava leaves was conducted by cold aqueous maceration for 24 hours which showed yield percentage of 15 %. The Guava leaves extract was applied on cotton woven fabric by exhaust method in 5g/l concentration. After desizing and scouring fabric weight, thickness, bulk and fabric count both in warp and weft direction of fabric increased significantly while tensile strength in both warp and weft directions and air permeability decreased significantly. The percent changes in bending length in both warp and weft directions, flexural rigidity and moisture regain were found to be non-significant. After Guava leaves extract treatment fabric weight and bulk of fabric increased significantly while tensile strength in warp and weft directions, flexural rigidity and air permeability decreased significantly. The changes in thickness, bending length, fabric count in both warp and weft direction and moisture regain were found to be non-significant. After washing weight, bulk, flexural rigidity and tensile strength in warp and weft directions of Guava leaves extract treated samples decreased significantly while air permeability increased significantly. The changes in thickness, bending length, fabric count in both warp and weft direction and moisture regain were found to be non-significant. Conclusively, the Guava leaves extract treated fabrics exhibited excellent efficacy against washing. However, it is needed to be renewed after every wash for good resistivity to washing.

Keywords: Cotton, extract, maceration, exhaust, bending length.

ASSESSMENT OF INFLOW CUT BACK RATIO IN WHEAT IRRIGATION

JEETENDRA KUMAR*, SHOBHARANI, R.K. SOHANE¹, WAJID HASAN AND A.K. PASWAN

Krishi Vigyan Kendra, Jehanabad, Bihar Agricultural University, Sabour (Bhagalpur), India, ¹Directorate of Extension Education, Bihar Agricultural University, Sabour (Bhagalpur), India

Farmers often use to irrigate wheat crop till water stagnation in the field for more than 12 hours thus there is excessive use of irrigation water. An on farm trial has been conducted at farmer's field in Jehanabad District of Bihar during Rabi season 2016-17 and 2017-18 to assess the cut back ratio in wheat irrigation and its effect on water saving, no. of irrigations applied and yield. The experiment was laid out in Randomized Block Design with 6 replications (no. of farmers). The trial was conducted with three technological options: TO 1- Irrigation till water stagnation in the field for more than 12 hours (Farmers Practice), TO 2- Irrigation using 85 % cut back ratio and TO 3-

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Irrigation using 90 % cut back ratio. Three irrigations were applied in each treatment by making 5 m wide border strips in wheat field. Result revealed that in the year 2016-17, TO 3 (wheat irrigation using 90 % cut back ratio) saved 481.6 cubic meter/ha (22.93 %) irrigation water, with B:C ratio of 2.09 as compared to 1.97 in farmers practice (TO 1) whereas in 2017-18, again TO 3 proved best technological options with a saving of 470.0 cubic meter/ha (22.3 %) irrigation water with B:C ratio of 1.97 as compared to 1.81 in farmers practice. Findings of the study indicated that practice of water stagnation in the wheat field for more than 12 hours is not necessary for optimum production and water use can be lowered without yield reduction if irrigation is stopped at 90 percent cut back ratio followed by irrigation using 85 percent cut back.

Key Words: Cut back ratio, Irrigation, On farm trials, Technological options, Water saving

RECENT ADVANCES IN PRODUCTION TECHNOLOGY OF ONION (*ALLIUM CEPAL.*)

JEEVITHA, D., AND UMESH CHIMMALAGI

Department Of Horticulture, Uas Dharwad

Onion is an important export earning vegetable crop worldwide and has been used in various forms as food. There are different types of onion available depending on shape, size and color. Processing industry uses it in the form of dehydrated onion flakes and powder, one of the remarkable features of onion is its excellent transportability. China ranks first followed by India with an area of 1270000ha production of 21564 000MT. The major Onion producing states includes Maharashtra 27.09MT /ha, Gujarat 25.48MT/ ha Karnataka stood 16th position in productivity *i.e.*, 14.16 MT/ha during 2017. There are some constraints in onion production like poor seed germination, nutritional deficiencies, lack of storage life, and most of the onion is production is under low rainfall areas and most of the onion growing area fall under *rabi* season to avoid these production constraints there are some recent technologies like drip irrigation, fertigation, raised bed cultivation, seed priming, seed production, improved storage structures introduced by NAFED Nasik, development of varieties or hybrids suitable for both *kharif* and *rabi* season. Considering its export potential and demand there is a need for improving the productivity of onion by adopting above said technologies to balance the fluctuations in the onion production

ANIMAL HEALTH: INNOVATIONS AND CHALLENGES AHEAD

JHABAR MAL TETARWAL* AND SUMAN CHOPRA M.SC. STUDENT**

Department of LPM (Livestock Production and Management) Sam Higginbottom University of Agriculture, Technology & Sciences Allahabad -211007, U.P., India, Department of P. Path.(plant pathology) Rajmata Vijayaraje Scindia Krishi Vishwa Vidyalaya Gwalior- 474002, M.P. India

A major area for product innovation will be animal feed. Policymakers can encourage the intensification of food production by providing farmers with innovative, targeted incentives. ... Food safety is a global public good that is dependent on the resources allocated to animal health. Modern animal health, as we now recognize it, began in 1761 with the founding of the world's first veterinary medicine school in Lyon. Since then, the animal health industry has been responsible for a steady stream of innovation. The first vaccines against anthrax and rabies were developed in the late 18th century, with protection against other common diseases, such as foot and mouth and brucellosis following in the early 1925s. It is a contributor to STAR-IDAZ, the global Strategic Alliances for the Coordination of Research on the Major Infectious Diseases of Animals. It is also identifying and bridging research gaps in over 35 targeted and emerging diseases through developing vaccines, diagnostics and treatments. A world where population growth is outstripping food supply agricultural and especially animal- biotechnology, needs to be swiftly implemented in all walks of life. The full realization of the agricultural biotechnology revolution depends on both continued successful and innovative research and development activities and on a favorable regulatory climate and public acceptance.

Keyword food safety, medicine, diseases, agriculture biotechnology, etc.

INTEGRATED FARMING AND SMART FARMING COMBINATION: A KEY OF SUSTAINABILITY

JITENDRA CHOUDHARY, GOPAL LAL DHAKAD AND MANISH YADAV

(Department of Soil Science And Agricultural Chemistry) SKN Agriculture University, Jobner, Jaipur Rajasthan 303328, e-mail: jc985274@gmail.com

Since Integrated Farming System (IFS) is an interrelated complex matrix of soil, water, plant, animal and environment and their interaction with each other enable the system more viable and profitable over the arable farming system. It leads to produce the quality food. Diversified systems consist of components such as crops and livestock that co-exist independently from each other. In particular, HEIA farmers can have pigs, dairy and crops as quite independent units. In this case the mixing of crops and livestock primarily serves to minimize risk and not to recycle resources. Smart farming reduces the ecological footprint of farming. Minimized or site-specific

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

application of inputs, such as fertilizers and pesticides, in precision agriculture systems will mitigate leaching problems as well as the emission of greenhouse gases. Smart farming can make agriculture more profitable for the farmer. Decreasing resource inputs will save the farmer money and labor, and increased reliability of spatially explicit data will reduce risks. Optimal, site-specific weather forecasts, yield projections, and probability maps for diseases and disasters based on a dense network of weather and climate data will allow cultivation of crops in an optimal way.

INFLUENCE OF PLANTING METHOD'S AND ORGANIC MANURE'S ON PHYSIOLOGICAL CHARACTERS OF KHARIF ONION (*ALLIUM CEPA* L.)**JITENDRASINGH GURJAR¹, S.S. SINGH², MANOJ KUREEL³ AND P.K.S. GURJAR⁴***M.G.C.G.V.V., Chitrakoot, Satna, M.P., R.V.S.K.V.V., Gwalior, M.P.*

The experiments were conducted at the farmer's field in the near College of Agriculture, Gwalior (M.P.) during two consecutive years of *Kharif* seasons in 2013-14 and 2014-15 to evaluate the influence of planting method's and organic manure's on physiological characters of *Kharif* onion in Gwalior conditions. Results revealed that the physiological parameters like Fresh weight of plant (g), Dry weight of plant (g), Crop growth rate (g/m²/day), Absolute growth rate (g/day), Relative growth rate (g/g/day) and Leaf area (cm²) were seedlings transplanted on ridges resulted significantly highest values at 40, 60, 80, 100 and 120 DAT over those transplanted in furrow and flat beds. Furrow planting method was also found significantly superior to flat planting method for all the physiological parameters. Among all the treatments of organics, application of poultry manures @ 4.2 t/ha resulted in significantly highest values of these physiological characters. The second best treatment was S₄ (VC 4.2 t/ha) followed by S₂ (FYM 25.0 t/ha). The PSB inoculated seedlings produced more fresh and dry weight per plant, whereas diameter of neck was superior under *Azospirillum* inoculated seedlings. Phosphorus is one of the essential major nutrients and needed in adequate amounts in the available form for growth and reproduction of plants. Seedlings inoculated with PSB transplanted on ridges with 25.0 t FYM/ha and PSB 5 kg/ha accrued the highest net monetary return amounting Rs. 97060/ha followed by P₃S₂B₂ (Rs. 93790/ha) while the highest B: C ratio of 2.65 was obtained by ridge transplanting with 12.5 t FYM/ha and PSB 5 kg/ha.

Key Words: Onion, Planting method, Organic nutrient sources, Bio-fertilizer, physiological character

INDIGENOUS PEST AND DISEASE MANAGEMENT : A PRACTICES FOR ORGANIC FARMING**JITENDRASINGH SHEKHAWAT; DAYA SHANKAR MEENA AND KISHORE KUMAR DAS***College of Agriculture, Swami Keshwanand Rajasthan Agriculture University, Bikaner- 334006*

Indigenous method of cultivating crops using self reliance locally available resources without external inputs. Traditional farming system is an ecologically based age-old farming system developed by ancient farmers through generations of their interaction with nature and natural resources for food, fodder and fiber and this concept is used for Indigenous pest and diseases management. Some of the indigenous traditional knowledge (ITK) being used by these traditional farmers in all the system of crop cultivation have been explained with rationale which may be use for integration in the existing IPM concept of organic farming.

NEW METHOD FOR NUTRIENT APPLICATION FOR PRODUCTION OF LOW POTASSIUM TOMATO FRUITS IN HYDROPONICS TECHNIQUE**JITENDRASINGH SHIVRAN***SKN Agriculture University, Jobner, Jaipur (Rajasthan)*

Recently, chronic kidney failure becomes a global problem, and patients are often restricted for K intake because of the problem with excretion of excess K. So low K tomato fruit will improve the dietary habits of the patients and their QOL. In this study, a best method for the production of low K content tomato fruit was investigated. of producing tomato fruit with low K content was investigated. Medium-sized and cherry tomato (*Solanum lycopersicum* L.) cultivars were used, and the supply of K was restricted using hydroponic technology. In medium-sized tomatoes, fruit K content decreased 45% to 60% depending on cultivar by K withdrawal from the nutrient solution. Although total soluble solid content decrease, titratable acid content was also affected by K restriction and decreased 20% to 40% depending on cultivar. In either case, K withdrawn in hydroponic culture from anthesis of the 3rd truss was effective in producing tomato fruit with low K, and could decrease the fruit K content to at least 50% of the expected tomato fruit K content. Next study, we applied the newly developed management method, quantitative management, about nutrient supply in hydroponics to control the K supply more precisely. In quantitative management, total amount of nutrients necessary for the plants to achieve their life cycle is divided by the estimated cultivation period. And the calculated amount of fertilizers is supplied to the solution tank at every regular interval. Low K fruit (100 mg K/100 g fruit) was achieved when 0.9 g of potassium was supplied. From these results, restriction of K supply in

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

hydroponics with double or triple truss system is hopeful to produce low K tomato fruits, and quantitative control is thought to be more suitable for low K tomato production. Further study is necessary to expect the cultivation period accurately before the cultivation to plan the schedule of K supply.

Key words : Hydroponics technology, tomato fruit, quantitative management, potassium.

EXIGENCY OF PRECISION AGRICULTURE

JOGINDER KUMAR, SAWAN KUMAR AND KAVITA

Department of soil science

Precision agriculture (PA), satellite farming or site specific crop management (SSCM) is a farming management concept based on observing, measuring and responding to inter and intra-field variability in crops. Precision agriculture is a key component of the third wave of modern agricultural revolutions with new technological advancements in the agricultural revolution of precision farming. John Deere was the first to introduce this technology using GPS location data from satellites. A GPS-connected controller in a farmer's tractor automatically steers the equipment based on the coordinates of a field and save seed, fertilizer, fuel, and time. India, issues of agricultural sector range from low per capita productivity, scarcity of skilled labour, high cost of cultivation and insufficient soil management practices which is improve by practices of precision agriculture. There is a lot of technology used to make modern agriculture more efficient. For example, some farmers use global positioning systems (GPS) and GPS-computer guided tractors and harvesters. Precision agriculture is geographical site-specific practices may include: electromagnetic soil mapping, collection of soil sample and crop yield data collection, aerial imager, crop or soil colour index maps, soil types, soil characteristics, drainage level, potential yields. Each of these geo-referenced data layers helps subdivide a large field area into smaller management zones. Using small management zones reduces waste while increasing production potential. One example of a precision agriculture practice is to evaluate the natural soil variability of a field. If the soil in one area holds water better, crops can be planted more densely and irrigation can be sparing. Hence, precision agriculture is a way to produce more food at a fraction of the cost and conserve soil for sustainable food production in climate smart agriculture.

PHENOTYPIC DIVERSITY IN PEARL MILLET [*Pennisetum glaucum* (L.) R. BR.] GERMPLASM LINES

JYOTI KAUSHIK¹, DEV VART¹, MUKESH KUMAR¹, ANIL KUMAR¹ AND RAMESH KUMAR¹

¹*Department of Genetics and Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar (Haryana) India-125004*

For effective trait selection, it is very important to have knowledge of association between traits and heritability. So, a study on phenotypic diversity in pearl millet [*Pennisetum glaucum* (L.) R. Br.] was intended in a set of 48 maintainer lines using 9 quantitative traits. Significant mean sum of squares indicated presence of sufficient variation in the lines. The GCV were slightly lower than PCV indicating the slight influence of environment on the expression of characters. Number of productive tillers/plant, plant height, 1000 grain weight, grain yield/plant had high heritability with high genetic advance as % of mean suggesting the prevalence of additive gene action in their inheritance which suggest that selection will be more effective based on these traits. Correlation coefficient analysis revealed that days to 50% flowering, spike length, number of productive tillers per plant, 1000 grain weight, dry and green fodder yield were significantly and positively correlated with grain yield per plant. The traits, days to 50% flowering, spike length, number of productive tillers/plant had high significant direct contribution towards grain yield/plant for which indirect selection can be made in future breeding programme to enhance grain yield.

Keywords: Phenotypic diversity, GCV, PCV, correlation coefficient, path analysis, pearl millet

BIOFERTILIZERS : A HAND TOWARDS ORGANIC AGRICULTURE

JYOTI SHARMA^{1*} AND DEEPAK KUMAR²

¹*Department of Soil Science, ²Department of Horticulture, CCS Haryana Agricultural University, Hisar, India-125004*

Essential plant nutrient mainly nitrogen (N), phosphorus (P) and potassium (K) are supplied by fertilizers. These fertilizers adversely affect human health. Due to this reason, farmers are growing crops without use of any fertilizer. Biofertilizers plays an important role in organic agriculture. A biofertilizer is a substance which contains living microorganism which, when applied, colonize the rhizosphere of the plant and promote growth by supplying nutrient to the host plant. They have capability to provide required nutrients to the crop in sufficient amount that enhance the crop yield. They not only contribute in plant growth, but also protects plants from pathogens by secreting antibiotics. Biofertilizers are now gaining emphasis among small and marginal farmers due to low cost. Biofertilizers add nutrients through nitrogen fixation, solubilizing phosphorus, and synthesis of growth-promoting substances. They provide 'eco-friendly

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

organic agro-inputs. Biofertilizers are effective even under semi-arid conditions. Biofertilizers like blue green algae (BCA), *Rhizobium* and *Azotobacter* have been in use from a few years. Bacteria and cyanobacteria has the property of nitrogen fixation while mycorrhizal fungi withdraw nutrients from organic matter for the plant with which they are associated. They maintain fertility and natural habitat of the soil. Most biofertilizers also secrete hormones like auxin, cytokinin and vitamins which are essential for plant growth. They increase the yield of plant by 15-35%. Overall, the important role of biofertilizers makes them a powerful tool for organic agriculture.

Keywords: Biofertilizers, Antibiotics, *Rhizobium*, *Azotobacter*, Eco friendly

OPTIMIZATION AND CHARACTERIZATION OF SIDEROPHORE PRODUCING PLANT GROWTH PROMOTING BACTERIA FOR ENRICHMENT OF IRON CONTENT IN WHEAT

JYOTI SINGH* AND AJAY VEER SINGH

Department of Microbiology, College of basic Science and humanities, G.B.P.U.A&T, Pantnagar, U.S. Nagar, Uttarakhand, India

More than two billion people are affected from micronutrient deficiencies of iron, vitamin A, iodine and zinc and it leads to important health consequences. To reduce the level of micronutrient deficiency it is required to biofortified our staple food crops. Implication of potential rhizobacteria for biofortification is a novel approach, can lead to augment micronutrient concentration in food crops along with significant yield and growth. In this context, present study was carried out for isolation and screening of plant growth promoting rhizobacteria from rice rhizosphere, Chiplun, Maharashtra, India and examined for their plant growth promoting abilities such as zinc solubilization, siderophore, ammonia, indole-3- acetic acid (IAA), hydrogen cyanide (HCN), exopolysaccharide and 1 aminocyclopropane 1-carboxylase (ACC) deaminase production potential. The potential bacterial isolate was further examined for optimization and characterization of siderophores. The results of optimization revealed that bacterium was able to produce siderophore (58 to 75% units) in the optimum condition of pH 8.0 at 36°C with sucrose and glucose as a C source. Furthermore, the characterization was done by means of spectrometric analysis which unveiled that type of siderophore produced by potential bacterial isolate was catecholate. The effectiveness of bacterial isolate was further analyzed through *in situ* plant growth promoting study in wheat (*Triticum aestivum* PBW-373) and assimilation of iron content in plant shoot and grains through AAS (Atomic absorption spectrophotometer), which showed significant influences on plant growth and productivity as well as iron assimilation in shoot and grains over control. Thus, the bacterial isolate can be developed as a potential bioinoculant reducing malnutrition intended for sustainable agriculture strategies after further evaluation and validation.

ORGANIC FARMING IN ORNAMENTAL CROPS

JYOTI VERMA*¹ NEHA VERMA*²

¹ *Department of Floriculture and Landscaping, PAU Ludhiana,* ² *Department of Vegetable Sciences, PAU Ludhiana*

Organic farming is a technique, which involves cultivation of plants in natural ways avoiding synthetic substances to maintain soil fertility and ecological balance. It is based on crop rotation, green manure, biological pest control, bio-fertilizers and organic manures. Flower cultivation nowadays is a way for diversification. By using inorganic fertilizers one can get higher yield but continuous use of agrochemicals deteriorates soil health and create imbalance to environment by polluting air, water and soil. There is an urgent need to reorient the research priorities towards developing alternate system in crop production. Many research works has been successfully conducted in different flower crops to observe the growth and yield characters under organic conditions. Organic flowers have longer vase life, drought tolerant and are free from chemical residues. The pre and post harvest quality was found to increase due to application of vermicompost, poultry manure and bio fertilizers. Poultry manure increased the growth and yield with maximum cost of benefit ratio in African marigold (Idan *et al.*, 2014). Application of vermicompost and VAM along with foliar application of vermiwash improved the floral attributes and shelf life of gladiolus cv. White Prosperity (Pathak and Kumar, 2009). Organic manures and bio inoculants improved the quality and yield of chrysanthemum (Bohra and Kumar, 2014).

Key words: Organic farming, flowers, balance, quality.

STUDIES ON INFLUENCE OF CROP BIODIVERSITY ON PIGEON PEA *CAJANUS CAJAN* L. (MILLSP.) INSECT COMPLEX.

***K.E. SHEWALE, B.P. BIRARI AND K.K. SURYAWANSHI**

Department of Entomology, Jawaharlal Nehru Krishi Vishwa Vidyalya, Jabalpur; Department of Plant Pathology, PGI, P.D.K.V. Akola, Maharashtra

Pigeonpea crop accounts ~5% of global acreage (4.16 million ha) and production (2.85 million tonnes), of which Asia is nearly the sole contributor (Ahlawat *et al.*, 2005). In India pigeonpea occupies an area of about 4.42 million ha with a total production of 2.89 million

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

tonnes with productivity of 655 kg/ha (Anonymous, 2011). In the country, the crop is extensively grown in Uttar Pradesh, Madhya Pradesh, Maharashtra, Karnataka, Andhra Pradesh and Gujarat. Studies on insect pest complex and their natural enemies in three diverse crop habitats *i.e.* pigeonpea bordered with maize (PP+M), bordered with sorghum fodder (PP+S) and pigeonpea sole unprotected and protected (PP + UP and PP+P), revealed that the following insects were recorded the pigeonpea crop. Jassid, *Empoasca fabae* Harris (Hemiptera: Cicadellidae); Aphid, *Aphis craccivora* Koch (Hemiptera: Aphididae); Leaf webber, *Grapholita critica* Myer. (Lepidoptera: Tortricidae); Red pumpkin beetle, *Raphidopalpa foveicollis* Lucas. (Chrysomelidae: Coleoptera); Green stink bug, *Nezara viridula* Linn. (Hemiptera: Pentatomidae); Cow bug, *Otinotus oneratus* W. (Hemiptera: Membracidae); Tur plume moth, *Exelastis atomosa* Walsingham (Lepidoptera: Pterophoridae); Pod bug, *Clavigralla gibbosa* Spinola (Hemiptera: Coreidae); Pod fly, *Melanagromyza obtusa* Malloch (Diptera: Agromyzidae); Thrips, *Megalurothrips usitatus* Bagnall (Thysanoptera: Thripidae); and Gram pod borer, *Helicoverpa armigera* Hub. (Lepidoptera: Noctuidae).

Diversification of crop habitat significantly influenced the incidence of pod infesting pest complex. Pigeonpea sole under protected condition was found to be most promising as it recorded minimum grain damage by pod infesting pest complex and registered highest grain yield, followed by pigeonpea bordered with maize, and sorghum fodder and highest damage and lowest yield pigeonpea sole under unprotected condition. Incidences of insect on border crop and parasitization by *C.chloridae* and *Carcelia* sp.

EFFECT OF *PLEUROTUS EOUS* SUPPLEMENTED DIETS ON THE ALBUMIN, GLOBULIN AND TOTAL PROTEINS IN EXPERIMENTAL ANIMAL (MALE ALBINO WISTAR RATS)

*K. GANESH SARAVANAN, S. SENTHIL MURUGAN, AND A. ESWARAN

Department of Plant Pathology, Annamalai University, Chidambaram, Tamil Nadu, India.

India blessed with various climatical condition which seems to be quite suitable for large-scale production of Oyster mushroom *P.eous*. Hence studies were taken up with an objective to find new technologies to test the Albumin, Globulin and Total Proteins of *P.eous*. With regard to the studies on medicinal properties of *P.eous*, The level of albumin, globulin and total protein showed steady increase in the rats co-administrated with various levels of *P.eous* the level of RBC, WBC, hemoglobin and haematocrit showed a significant increase in rats co-administered with different concentration and durations of observation. Among the three levels of *Pleurotus eous* diet tested, the 10 per cent level recorded the maximum increase level when compared to 2.5 and 5 per cent level in the both serum and liver. The level of albumin, globulin and total protein are analysed by feeding rats with 10 per cent of *Pleurotus eous* diet (Group D) over a period of 90th day observed a gradual increase when compared with control (Group A) and therefore the study revealed the beneficial effects of *P.eous* on the increased level of albumin, globulin and total protein content.

Key words : *Pleurotus eous*, Hemoglobin, Haematocrit, Albumin, Globulin, Wistar rats .

POLYSACCHARIDE PROFILING OF *XANTHOMONAS AXONOPODISPV. PUNICAE* CAUSING BACTERIAL BLIGHT OF POMEGRANATE

*K. K. SURYAWANSHI K. E. SHEWALE, B. P. BIRARI

*Department of Plant Pathology and Agril. Microbiology, KDSP College of Agriculture, Nashik 422013, Maharashtra, *Department of Entomology, HHSSMS College of Agriculture, Malegaon 423105, Maharashtra

Lipopolysaccharides (LPS) of *Xanthomonas axonopodispv. punicae* constitute one of the main component of the outer membrane of this bacteria which play an essential role for bacterial growth and survival. Similarly, the capacity of this bacteria to induce persistent water-soaking in leaves plays a crucial role during pathogenesis that seems to be accomplished by synergistic interaction between bacterial Exopolysaccharides (EPS) and plant polymers. We have studied Lipopolysaccharides (LPSs) and Exopolysaccharides (EPS) profiling of 23 different isolates of *Xanthomonas axonopodispv. punicae* in present investigation. Exopolysaccharides profiling of isolates showed that the amount of exopolysaccharides in the wall of different *X. axonopodispv. punicae* isolates varied from 98.94 to 183.90 µg/mg. Higher exopolysaccharides was found in isolate KD-11 whereas lowest exopolysaccharides containing isolate was GBV-21. Whereas, Lipopolysaccharide profiling of these isolates showed that isolate KD-11 contained higher amount of lipopolysaccharides *i.e.* 139.90 µg/mg. while, less amount of lipopolysaccharides was observed in isolate RH-22 *i.e.* 48.86 µg/mg, others isolates contained varied amount of LPS.

INDUCTION OF MOISTURE STRESS TOLERANCE IN GERMINATING SEEDS OF CHILLI (*CAPSICUM ANNUM* L.) THROUGH SEED PRIMING

K. STEPHEN, F.A. KHAN, S. NARAYAN AND K. HUSSAIN

Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar 190025, Distt. Srinagar (J&K)

To ascertain the role of seed priming for mitigating the adverse effects of moisture stress during seed germination, seeds of chilli cv.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Kashmir Long-1 were primed in water (30 hours), -0.5MPa solution of PEG 6000 (18 hours), 8x dilution of vermiwash (30 hours) and 5ppm solution of melatonin (30 hours) and unprimed seeds were taken as control and tested for their germination potential under normal (no stress) and moisture stress conditions. Seed priming is simply the hydration of seeds by exposing them to aqueous solution and re-drying to original moisture level. For the germination test under normal and moisture stress conditions 50 primed seeds of each priming treatments were sown in nursery trays and supplied with distilled water and -0.5 MPa solution of PEG 6000, respectively. Data indicate that germination potential of chilli seeds was significantly declined under moisture stress condition while as different priming treatments tend to improve the germinability of seeds particularly under moisture stress condition. Among different priming treatments melatonin priming resulted in highest germination as well as seedling emergence percent (90.66 % & 87.33 %), days to 50% of germination & days to 50% of emergence (G_{50} 10.0 & E_{50} 12.33), Timson's index (35.24), radical & plumule length (4.74 & 4.39 cm), seedling root & shoot dry weight (0.15 & 0.05 g/ seedling), seedling vigour index I & II (810.59 & 17.50), leaf chlorophyll content and its stability (0.86 mg/g & 97.92 %) and proline content (33.77 μ mol/g) followed by osmopriming against the minimum values in control with respect to germination as well as seedling emergence percent (83.33 % & 74.00 %), speed of germination & seedling emergence (G_{50} 11.67 & E_{50} 14.00), Timson's index (30.04) radical & plumule length (3.80 & 3.79 cm), seedling root & shoot dry weight (0.09 & 0.02 g/seedling), seedling vigour index I & II (632.71 & 10.80), leaf chlorophyll content and its stability (0.48 mg/g & 72.72 %) and proline content (17.14 μ mol/g).

STUDIES ON INFLUENCE OF CROP BIODIVERSITY ON PIGEON PEA *CAJANUS CAJAN* L. (MILLSP.) INSECT COMPLEX.

A STUDY ON EVALUATION OF DEVELOPMENT -AGRICULTURE AND INFRASTRUCTURE IN DEVIPATAN DIVISION OF EASTERN UTTAR PRADESH

K.K. MOURYA, UDAYBHAN MAURYA, SARVESH KUMAR AND RAVI PRAKASH GUPTA

Department of Agricultural Statistics, Narendra Deva University of Agriculture and Technology Narendra Nagar, (Kumarganj), Faizabad- 224 229 (U.P.) India.

Socio-economic development is one of the most important concerns of all the countries. Present study is regarding the level of development of 4 Districts and 44 blocks of Devipatan division in Eastern Uttar Pradesh. Secondary data on a number of indicators published by Uttar Pradesh Government for the year 2012-2013 have been used in the study. Principal Component & Factor Analysis methods along with techniques adopted by Narain *et al.* have been used. The level of development was examined for Agriculture and Infrastructure systems. The Ranking of Districts is- Gonda, Behraich, Sravasti and Balrampur in respect of Agriculture & Infrastructure. Indicators available at District Level are more informative than Block level Indicators. Variables/Indicators like- Production & Productivity of Food grains, Gross value of agriculture produce, % irrigated area have been found important in this study. These

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

variables are not estimated at Block levels. Development process of any system is dynamic in nature and depends on large number of parameter. This study attempted to capture latest dynamics of development in devipatan division in Eastern Uttar Pradesh in respect of three dimensions- Agriculture, and Infrastructure. Technique adopted by Narain et al. (1991) have been used in addition to principal component and factor analysis. Ranking seems to very close to ground reality and provides useful information for further planning and corrective measures for future development of Eastern Uttar Pradesh's District. The Composite Indices (C.I) of development in respects of 23 developmental indicator for the total 4 Districts and 44 block of Eastern Uttar Pradesh have been estimated for the year 2011-12. The Block Jamunha was showed a higher level of development (C.I=1.05) in Agriculture development and Infrastructure development Districts Karnailganj (C.I=0.73) followed by the Block Mihipurwa (Agriculture, C.I=1.83), and Block Katra Bajar (Infrastructural C. I = 0.74). Principal Component and Factor Analysis seem to be more reliable at District level in comparison to Block levels. Correlation Matrix of Indicators at District level is indicating strong trends but at Block level the trends are moderate or weak. Ranking of Block and its comparison with previous study in 2004 shows many changes that requires further investigation.

EFFECT OF ROOT AND FOLIAR APPLIED FERTILIZER ON YIELD OF POTATO AND CABBAGE

K.M.S. KODIKARA¹, H.M.M.S.K. SENEVIRATHNE², B.W.P.K. SAMARAWEEERA¹ AND I.P.YAPA²

¹Regional Agriculture Research and Development Centre, Diyatalawa Road, Bandarawela, Sri Lanka., ² Sabaragamuwa University of Sri Lanka, Belihuloya, Sri Lanka.

An investigation was conducted to estimate the absorption efficiency of root and foliar applied nutrients on cabbage and potato in Regional Agriculture Research and Development Centre, Bandarawela (6°49'59.99" N 80°58'59.99" E), Sri Lanka during 2014 and 2015. Experiment was conducted in 1x1x0.2 m wooden boxes filled with soil less medium (Cair dust based) and maintained in protected environmental conditions. A complete nutrient mixture (Albert solution) was applied directly into plant roots, sprayed into leaves to drain out the excess into medium, foliar application only without allowing draining out to medium and compared with no fertilizer control. Experiment was laid out in CRD with three replicates. Plant growth and yield were recorded and Nutrient Use Efficiency (NUE) was calculated. Results showed that, growing medium pH and EC were varied with initial values and after the crop pertinent to fertilizer application methods and root applied treatment showed higher variations. Root application of plant nutrients was recorded significantly higher yield than foliar application. Significant yield increment recorded by root absorbed nutrients from drained portion of fertilizer to growing medium than only foliar applied treatment according to plant growth and yield of cabbage and potato. It reflected superior NUE in root applied plant nutrients and always cabbage shows higher NUE than potato. Foliar application was not able to fulfill the total plant nutrient demand of cabbage and potatoes.

Key Words Cabbage, Fertilizer, Foliar application, Potato, Root application

DOUBLING FARMERS' INCOME THROUGH INNOVATIVE APPROACHES

KAILASH CHAND JAKHAR

Rajasthan College of Agriculture, Maharana Pratap University of Agriculture and Technology, Udaipur

In an effort to boost the agriculture sector, the government has set the ambitious goal of doubling farmers' income by 2022. At the current 3-per-cent growth rate it would take 25 years to double farmers' income. In doing so, it has unveiled strategies ranging from a focus on irrigation to provision of quality inputs, investments in warehousing and cold chains, promotion of food processing and crop insurance schemes, among others. What is clear is that to transform the agriculture sector, it needs to move from a production-driven system to a demand-driven food value chain that increasingly connects the consumer to the producers. Doubling of farmers' income must be attempted by creating a framework where all related agencies come together and work in harmony, with a maestro conducting that orchestra. Doubling rural income in nominal terms is possible by increasing agriculture output & minimum support prices (while keeping inflation below 5%), doubling rural income in real terms would be a daunting task considering increasing agriculture output by 12% every year with no additional land likely to be utilized for agricultural activity. There is every possibility not only to double the income of farmers through enhancement in productivity, changes in cropping pattern, inspire additional income through many supplementary activities but also provide stability in farmers' income. If a large number of agricultural households are connected to mass consumption markets both domestic and global the objective of doubling farm income doesn't seem daunting. The focus must shift from increasing per acre productivity to gainfully employing farm households in other farm-related activities. The explosion of the services sector allowed that to happen in urban India. We need a similar catalyst for the lowest end of the income spectrum among rural households.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

AILANTHUS BASED AGROFORESTRY SYSTEM IN ARID AND SEMI-ARID REGIONS

KAJAL AND NEHA SAINI

Department of forestry, CCS Haryana Agricultural University, Hisar-125004, India

Arid and semi-arid zones are characterized by hostile climatic conditions i.e., low and erratic rainfall and intense solar radiation coupled with high wind velocity, poor nutritional status of soil with low water holding capacity, poor quality and deep seated underground waters. In absence of favourable conditions for intensive agriculture, livestock rearing is an alternative source of livelihood of majority of the rural population in arid ecosystems of India. Therefore, to meet the increasing demand for fodder (green and dry) for livestock and food, fuel wood and timber etc. for human population on sustainable basis without degradation of land resources, the only alternative in the land productivity is agroforestry. Agroforestry plays an important role in meeting the diverse needs of people resorting to them as inter-dependent benefits of the three components, viz. trees, crops and livestock in addition to the 6Fs, i.e. food, fruit, fodder, fuel, fertilizer and fiber from limited land resources. After khejari (*Prosopis cineraria*), ardu (*Ailanthus excelsa*) is the only tree that not only feed to the animals but also used in manufacturing of plywood, match-sticks, toy and packing materials, medicines etc. Ardu reflects wider adaptability and higher tolerance to biotic and abiotic stresses hence, a potential species during drought/ climate change. The selection of ardu for commercially important agroforestry models to obtain higher productivity holds significance in producing fodder, fuel wood, timber etc. in arid ecosystem. Realizing its multiple uses, its cultivation in various systems extended and came out to be a profitable venture in agroforestry and silvi-pastoral system.

Keywords: *Ailanthus excelsa*, Mahaneem, Maharukh, Agroforestry, Ardu

CERTAIN MORPHOLOGICAL CHARACTERS IMPARTING RESISTANCE IN TOMATO AGAINST FRUIT BORER, *HELICOVERPA ARMIGERA* (HUBNER)

KALPANA BISHT, N.N. SINGH AND S.V.S RAJU

Department of Entomology and Agricultural Zoology, B.H.U, Varanasi 221005 (U.P.)

Tomato is one of the most preferred vegetable crops in the world with the total global area of 45,82,438 thousand ha and production of around 15,05,13,813 thousand tones. Despite of the good area, production is not up-to the mark as tomato is more prone to insect pests viz., tomato fruit borer, green house whitefly, serpentine leaf miner, etc due to its tenderness and softness as compared to other crops. Among them, the tomato fruit borer, *Helicoverpa armigera* (Hubner) is main bottle neck and causes heavy loss in yield. Host plant resistance or varietal resistance constitutes an important field of study with the hypothesis that different varieties/lines of tomato possess varied degree of population and infestation of *H. armigera*. The present studies were carried out on Vegetable Research Farm, IAS, BHU, Varanasi during 2017-18. On the selected twenty two tomato varieties/lines morphological characters viz. number of branches per plant, number of calyx per fruit, density of trichomes on the calyx, density of trichomes on the leaf surface, fruit pericarp thickness were measured and compared. The results showed that the correlation of branches per plant ($r=0.674$) and number of calyx per fruit ($r=0.373$) were significantly positive while density of trichomes on the calyx ($r=-0.522$), density of trichomes on leaf surface ($r=-0.322$) and fruit pericarp thickness ($r=-0.473$) exhibited significantly negative association with the damage of tomato fruit borer. The morphological characteristics used under present studies can be used as marker traits by breeders to develop insect resistant varieties/lines of tomato through breeding programs.

Keywords: Morphological characters, *H. armigera*, fruit infestation, correlation analysis

PARTIAL ROOT ZONE DRYING: AN EMERGING TECHNIQUE FOR INCREASING WATER USE EFFICIENCY AND QUALITY IN FRUITS UNDER ARID AND SEMI-ARID REGIONS

KALPANA CHOUDHARY, NIRMAL KUMAR MEENA, J P RATHORE² APOORVA PALLEL AND SONALI CHOUDHARY³

College of Horticulture and Forestry, AU, Kota Campus, Jhalawar (Rajasthan), ¹Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K), ²Department of Fruit Science, COH, YS Parmar UHF, Nauni-Solan (HP)

Irrigated agriculture depends on ground water and ground water going to be an ever-increasing pressure due to increasing water demand for cultivation of agricultural as well as horticultural crops. Partial root-zone drying is a modified, novel form of deficit irrigation method. It involves irrigating only one half of the root-zone in each irrigation event, leaving another half of root-zone to dry up to certain soil water content, than shifting irrigation to the dry side. In PRZD, generally the alternate wetting and drying sides of root system is to done on a 10-14 days interval. It alters the plant physiology by creating stress to the plants thus helps in reducing water loss from the plants. The stress results in poor growth but increase quality parameters like soluble solid contents, sweetness, antioxidants, defence related enzymes and also shorten the juvenile phase of plants, make them adaptable to semi-arid and dry areas. In fruit crops under partial

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

root zone drying can reduce irrigation water up to 50 per cent of the commercial irrigation and increase water use efficiency to the extent of 80-92 per cent. In grape, orange, mango, pomegranate and apple PRZD increases WUE and fruit quality without affecting the yield. Its usefulness has been proven in grapes, orange, pomegranate and apple. With changing climatic conditions and fluctuation in rainfall, shortage of available water resources, especially in arid and semi-arid areas, so there is urgent need to improve irrigation techniques and agricultural water management in the era of scared water condition.

PROBLEM, PROSPECTS AND MANAGEMENT STRATEGIES OF PULSE PRODUCTION UNDER RAINFED SITUATION

***KALPANASHARMA¹, DHARMENDRA GAUR¹, ANJU SHARMA² AND HEMLATA DHAKAD¹**

College of agriculture, RVSKVV, Gwalior, M.P, 474002, College of agriculture, RVSKVV, Gwalior, M.P, 474002

Agriculture production in rainfed regions constitute about 65% of the area under cultivation and account for about 40-45% of the total production in India. It is expected to suffer severe water crisis due to delayed monsoon, uneven rains distribution as a result of above climate change threats. But, pulses are one of the important segments of Indian agriculture after cereals with 25% share in the global pulse production and covering an area of about 263 m ha, majority of which falling under rainfed condition where irrigation facilities are inadequate or not available. Pulses are rich sources of protein and energy, but in india these are largely cultivated under energy starved conditions, mostly on marginal and sub-marginal land and more than three-fourth of the area under pulses is still rainfed resulting in poor crop productivity (Choudhary 2013). In India, production of pulses is around 19.3 million tonnes (ESI 2015) with a very low average productivity of 764 kg/ha. As a result, the productivity of the pulses in India is quite low. Besides, to meet the demand of pulses, India imports huge amount of pulses every year. Thus, there is a great challenge to enhance pulse productivity to meet out the national and local pulse requirements. India needs around 32 million tons of pulses by 2030, to feed the estimated population of about 1.68 billion. Global supply of pulses is limited, as India happens to be the largest producer and consumer of pulses. This is only possible when farmers adopt improved technologies in pulse production like moisture conservation, seed replacement with improved varieties, raised bed planting method, use of biofertilizers, foliar application of fertilizers at critical stages in rainfed areas, application of secondary and micro-nutrients and adoption of appropriate modules for integrated weed and pest management and appropriate crop management practices). However, a concerted effort by farmers, researchers, development agencies, and government are needed to ensure that India becomes self-sufficient in pulses.

KEYWORDS: Pulse production, Rainfed conditions, Strategies and Technology

PRECISION AGRICULTURE: A TOOL FOR DOUBLING FARMERS INCOME

KALPANA SINGH*, HARIOM KATIYAR, NAVEEN CHANDRA & S.K.LODHI

**Govt.P.G.College Shivrajpur Kanpur, SVPUAT, Meerut, U.P.*

Precision agriculture merges the new technologies borne of the information age with a mature agricultural industry. It describes an approach to the mechanized production of food and fiber in which production inputs (seed, fertilizer, irrigation, water, pesticides, etc.) are prescribed and applied and crop yields are monitored on a site-specific basis rather than the traditional whole field basis. The goal is not new but the new technologies now available, such as 'Global positioning systems' (GPS) and 'Geographical information systems' (GIS), allow the concept of precision agriculture to be realized in a practical production setting. Farmers are usually aware of their fields having variable yields across the landscape. These variations can be an outcome of poor management practices, soil properties and/or environmental characteristics. Soil properties that affect yields include texture, structure, moisture, organic matter, nutrient status and landscape position while environmental characteristics include weather, weeds, insects and diseases. Seeing this magnitude of variation prompts most farmers to ask how the problem that is causing the low yields can be fixed. There is no economical feasible method of "fixing" the depleted top soil areas in this field, so the management challenge is to optimally manage the areas within the field that have different production capacities. This does not necessarily mean having the same yield levels in all areas of the field. Precision farming is a direction of research rather than a destination. Extensive research on precision farming requires immediate attention of the researchers and policy makers. It should not be misunderstood that precision agriculture because of its sophisticated nature is only suitable for the large are resource rich farmers rather it could be more useful for a resource poor farmer. The goal is to optimize production inputs in order to maximize profit. When fully developed, PA also has the potential to minimize negative environmental impacts associated with production inputs (fertilizers, pesticides, water). In addition, fertilizer, plant population and even choice of crop hybrid/variety can be adjusted to account for changing soil types, fertility, pH differences, infiltration rates and slope aspect.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**EFFICACY OF ORGANIC AND INORGANIC NUTRIENT IN MANGO****KALYANI NAGRAJ¹, ISHWAR MARKAM², GULSHAN GAWDE³***Department of Fruit Science 2- Department of Floriculture 3-Department of Ag.Economics, Indira Gandhi Krishi Vishwavidyalaya (IGKV), Raipur, (C.G)*

A investigation was carried out for the Study on effect of organic, inorganic and biofertilizer on growth, yield and quality of mango cv. Amrapaliit was carried out during 2015-2016 at Horticulture Research Farm, Department of Fruit Science, Indira Gandhi Krishi Vishwavidyalaya, Raipur (C.G.), found that the application of 80% RDF + Cowdung slurry@10 lit/tree produced the highest shoot length, shoot girth, number of leaves per shoot, number of primary branch, length of panicle, number of panicle per rachis, number of flower per panicle and minimum flowering duration. Yield and yield attribute character like fruit length, fruit width, fruit volume fruit weight and number of fruit plant⁻¹ (140.33), fruit yield (29.60 kg tree⁻¹ and 11.84 MT ha⁻¹) was obtained under the treatment 80% RDF + Cowdung slurry@ 10lit/tree. Quality parameter like peel weight, pulp weight, stone weight, TSS, reducing sugar, non reducing sugar, total sugar, ascorbic acid, sugar acid ratio were maximum under the treatment 80% RDF + Cowdung slurry@10lit/tree. The peel per cent, pulp per cent and stone per cent were showed non- significant difference. The acidity was maximum under control. The nutrient status of mango leaves like N, P, K, Ca, Mg, Cu, Zn, Mn and Fe were also higher under the treatment 80% RDF + Cowdung slurry @10lit/tree. The treatment 80% RDF + Cowdung slurry@10lit/tree produced the maximum yield and also gave the highest gross return, net return and benefit: cost ratio which was closely followed by 100% RDF and 80% RDF + Vermiwash@ 10lit/tree.

EFFECT OF PLANTING DATES AND VARIETIES ON GROWTH AND QUALITY IN GLADIOLUS (GLADIOLUS HYBRIDUS HORT.) UNDER SUB-HUMID ZONE OF RAJASTHAN**KAMAL KISHORE NAGAR, ASHUTHOS MISHRA, SUSHMAPATIL AND J PRATHORE¹***Department of Floriculture & Landscaping, College of Horticulture & Forestry-Jhalawar, Agriculture University Kota (Rajasthan), Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar-190025*

A field experiment was conducted during winter season of 2015-16 to study "Studies Effect of Planting Dates and Varieties on Growth and Quality on Gladiolus (*Gladiolus hybridus* Hort.) under sub-humid zone of Rajasthan" having 15 treatment combinations of five Varieties (V₁- African Star, V₂- Hunting Song, V₃- Legend, V₄- PusaSrijana and V₅- Snow Princess) and three planting dates (D₁- 10th October, D₂- 25th October and D₃- 9th November). The treatment V₂D₁ (Hunting Song + 10th October planting) recorded the maximum plant height (116.10 cm), highest number of leaves per plant (8.77), main stem diameter (1.50 cm), number of florets per spike (15.8), spike length (91.80 cm), rachis length (57.90 cm), floret diameter (10.04 cm), vase life of spike (13 days), While the maximum leaf length (64.20 cm), leaf width (4.96 cm) in (V₃D₃) and maximum spike girth (0.91cm) was found in (V₁D₂). The growth and flowering quality was found superior in compare to other planting dates.

"CONSTRAINTS FACED BY FARMERS ABOUT SCIENTIFIC PRODUCTION TECHNOLOGY OF OKRA"**KAMAL KISHORE¹, PRAKASH SINGH², R.K. DOHAREY³, KAUSHIK PRASAD^{*4}, ATUL KUMAR⁵, ARVIND PRATAP SINGH⁶, MANOJ KUMAR⁷ AND SUBODH KUMAR⁸***^{1,2,3,4,5,6,7} Department of Extension Education, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India, ⁸Department of Veterinary Extension, College of Veterinary, N.D.U.A &T., Narendra Nagar, (Kumarganj), Faizabad (U.P.) 224229, India*

The study was conducted in Chhibramau and Talgram blocks of **Kannauj** district (UP) selected purposively, because these blocks one more popular for area and production of okra. A total number of okra growers were selected through random sampling from eight selected village's panchayats on the basis of ten respondents from each selected village panchayats. The some structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. Social problems in okra cultivation perceived maximum number of the respondents 87% with adopt a rank of first were agreed with the statements that damage due to lack of good seedling is the common problem, followed by damage due to pest and insect 85% at ranks second. Economic problems in okra cultivation perceived maximum number of the respondents 87.50% with adopt a rank of first were agreed with the statements that lack of Minimum Support Price is the common problem, followed by lack of grading, and middleman dominancy 85.50% at ranks second. Technical problems in okra cultivation perceived maximum number of the respondents 95% with adopt a rank of first were agreed with the statements that "highly susceptibility of diseases, insect and pests" is the common problem, followed by low keeping quality of okra varieties 93.00% at ranks second.

SUSTAINABLE APPROACH TO INTEGRATED PEST MANAGEMENT IN COLE CROPS**KAMALRAVISHARMA¹, SVS RAJU¹, RASHMIREKHA SINGH² AND RAMESH BABU S¹**¹Departem^t of Entomology and Agril. Zoology, I. Ag. Sc., B.H.U., Varanasi-221 005, ²Departem^t of Entomology, COA, OUAT, Bhubaneswar- 751 003

Cole crops belong to plants in the crucifer family within the Genus Brassica. Cole crops cultivated extensively in tropical and temperate regions in the world including India. The main constraint in the production of cole crops is the damage caused by insect pests complex from seedling to harvesting. In India, a total more than 40 insect pests have been recorded on cole crops. The extent of damage caused by these insect pest from 7 to 90 per cent with consequent reduction in yield from 20 to 80 per cent. In the last century the farmers have added one more weapon to their armoury to use against the insect pest, *i.e.* the use of chemical pesticides. However, over reliance and indiscriminate use of pesticides resulted in a series of problems in the agro-ecosystem mainly, the development of resistance in insects to insecticides, resurgence of treated population, out-break of secondary pests into primary nature, environmental contamination and residue hazards, destruction of natural enemies of insect pests, expenses on pesticides, equipment, labour etc. All these problems contributed to a new way of thinking the sustainable approach for concerning insect pest control practices, *i.e.* Integrated Pest Management (IPM). Integrated pest management is a systems approach to pest control that combines the all suitable management practices with the judicious use of pesticides. IPM is a dynamic and constantly evolving system in which all the suitable control tactics and available surveillance and forecasting information are combined into a holistic management programme delivered to the farmer at requisite interval as part of the sustainable crop production technologies in cole crops.

Keywords: Cole crops, Insect pests, Insecticide, Integrated Pest Management.

EFFECT OF ZINC AND BORON ON GROWTH AND YIELD OF MAIZE (ZEAMAYS L.)**KAMAL SINGH, SATYBHAN SINGH AND PRADEEP KUMAR***School of Agricultural Sciences & Engineering, IFTM University, Moradabad-244102*

Maize (*Zea mays* L.) is one of the most important cereal crops throughout the world. The present study entitled impact of Effect of Zinc and Boron levels on maize in north-western Uttar Pradesh plain zone of India was carried out a School of Agricultural Sciences and Engineering, IFTM University Moradabad in 2017-18. the effect of Zinc has a pronounced effect on the important processes of plants like photosynthesis, protection against reactive oxygen species, nitrogen metabolism, carbonic anhydrase activity, chlorophyll synthesis and resistance to biotic and abiotic stresses Boron deficiency depresses commercial corn yield primarily through grain set failure, and Zinc and Boron both play an important role in the basic plant functions like photosynthesis, protein and chlorophyll synthesis. With Treatment T₁ (Control), T₂ (Zinc Soil Application), T₃ (Zinc Foliar Application), T₄ (Zinc Two Foliar Application), T₅ (Zinc Soil Application + Zinc Foliar Application), T₆ (Boron Soil Application), T₇ (Boron Foliar Application), T₈ (Boron Two Foliar Application), T₉ (Boron Soil Application And Foliar Application), T₁₀ (Zinc + Boron Soil Application), with three replication. Observation to recorded, Plant height (cm), Number of leaves plant⁻¹, Fresh weight (g), Plant dry weight (g), Stem girth (cm), Days taken to 50% tassel, Days taken to 50% silking, Crop growth rate (CGR), Absolute growth rate (AGR), Yield Attributes, Number of cobs plant⁻¹, Number of grains row⁻¹, Number of grains cob⁻¹, Seed index(g), Grain yield (q ha⁻¹), Strove yield (q ha⁻¹), Biological yield (q ha⁻¹), Harvest index (%), Economics, Cost of cultivation, Gross return, Net return, Beneficial cost (B:C) ratio.

CHARACTERIZATION OF MAIZE GENOTYPES FOR ROOT ARCHITECTURAL TRAITS USING AGAR MEDIATED SCREENING**KAMALUDDIN*, I. A. DAR, Z. A. DAR, P. A. SOFI, A. A. LONE AND A. R. VAID****, Deptt. Of Genetics & Plant Breeding, CoA, BUAT, Banda, Division of GPB, FoA/RRS Wadura (SKUAST-Kashmir)*

The essential function of root is to uptake water and nutrients for plant growth, function as storage organs, attach plants to the soil and are the site of interactions with pathogenic and beneficial organisms in the rhizosphere. Roots are also crucial for nutrient and water acquisition and can be targeted to enhance plant productivity. Because of the underground location of root, it is challenging task for plant breeder to phenotype it and selection of plants with desirable root characteristics. Available approaches for root phenotyping in laboratory, greenhouse and field encompass simple agar plates to labor-intensive root digging. The present study was carried out in the laboratory conditions of Division of Genetics and Plant Breeding, Faculty of Agriculture, Wadura, SKUAST-Kashmir. The experimental material was comprised of thirteen released varieties of maize from different parts of India. The present study showed that Pratap Makka-5 had shallowest root angle and Pratap Makka-4 had steepest root angle. No. of seminal roots were highest in Kishan Ganga-2 and lowest in Aravali Makka-1. Length of tap root was highest in Kishan Ganga-1 and lowest in Pratap Makka-4. The results obtained from this study suggested that selection for root angles, either of seminal roots or of lateral roots, may be helpful to identify genotypes with a root

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

architecture system better adapted to water-limited environments.

NUTRIENT INTERACTION IN PLANT AND SOIL

KAMLESH YADAV¹ AND ATUL DHANSIL²

¹*Deptt. of Agril. Chem. and Soil Science, Rajasthan College of Agriculture, MPUAT, Udaipur, Rajasthan,* ²*Deptt. of Agril. Chem. and Soil Science, College of Agriculture, JAU, Junagadh, Gujarat*

Agriculture is the back bone of India, in which nutrient is the one of the most important input of the crop production. The nutrient interaction is one of the factors that affect availability of nutrient to the crop. Interaction occurs when the level of one production factor influences the response to another factor. It may be positive or negative very from nutrient to nutrient or crop to crop at both plant or soil level. The positive interactions have served as the science-based justification for development of a “balanced” plant nutrition programme. The positive nutrient interaction increased the soil fertility as well as crop productivity, whereas the negative interaction suppressed the soil fertility status as well as crop productivity. The interaction of nitrogen with phosphorus, potassium and sulphur was found synergistic effect on yield of almost crops. In soil, interactions of N x K and P x S had synergistic effects. In contrast, combination of phosphorus and zinc had antagonistic effect on available phosphorus and zinc in soil. It is essential to understand the mechanism of nutrient interaction in soil their effect on plant metabolism for higher crop production and efficient utilization of inputs in soil and plant. For obtaining higher crop production and maintaining soil fertility, there is a need to consider the nutrient interaction for nutrient management.

Key words: nutrient, interaction, positive or negative, productivity

STRATEGY FOR GOAT FARMING IN THE 21ST CENTURY

DR KAMLESH SINGH

Associate Professor, Deptt., of AH & Dairying, KAPG College Allahabad (UP)

The objective of this paper is to contribute to progress in the choices of strategies for further development of goat farming in the 21st century. During the last 20 years, the number of goats around the world increased (by about 60%) not only in the countries with low income (75%) but also in those with high (20%) or intermediate (25%) income. This situation is due to the capacity for adaptation by goats to very different environments, to the development of goat farming in developing countries where subsistence farming, barter economy and community culture are important, and where the market economy is relatively limited, and to the ecological image of goat farming and products in developed countries. Goat farming is in a good position to pursue its development in the 21st century, if a satisfactory policy is applied tactfully. For that, the factors explaining goat farming success during the end of the 20th century must be maintained and developed as the social aspects of goat farming in developing and developed countries, particularly in land management and the sociological integration into an economically sustainable life. Moreover we have to improve or maintain the good image of goat products. The two main improvements to bring into goat farming in the 21st century concern research organisations, which must encounter the needs of goat farmers and be well adapted to different production systems in order to lower the research deficit in the goat sector, and investments for better supplies particularly to the poor goat farmers.

EFFECT OF WEATHER PARAMETERS ON KHARIF RICE FOR BETTER PLANNING AND MANAGEMENT IN BHARUCH (GUJARAT)

K. B. BANAKARA^{1*}, H. R. PANDYA¹ AND Y. A. GARDE²

¹*Department of Agricultural Statistics, Navsari Agricultural University, Navsari, Gujarat 396 450,* ²*Department of Agricultural Statistics, College of Agriculture, Navsari Agricultural University, Waghai, Dang, Gujarat 394 730*

India economy mainly depends on agriculture sector as it account 18 percent of national GDP and it is most important occupation for most of the Indian families so; it is the soul of Indian economy. Rice is the most important staple food in India which play crucial role in daily requisite of diet. In the current study statistical crop modeling was engaged to provide forecast in advance. In this paper Multiple Linear Regression (MLR) Technique and Principal component analysis were derived for estimating average rice production for the Bharuch of district in south Gujarat. The weather indices were developed using correlation coefficient as weight to weekly weather parameters for the years from 1990 to 2012. The cross authentication of the developed forecast model were confirmed using data of the years 2013 to 2017. It was observed that value of Adj. R² varied from 70.90 to 77.20 in different models. The study discovered that high value of Adj. R² was obtained in the model and which indicated that it was appropriate forecast model than other models. Based on the outcomes in Bharuch district, MLR techniques found to be better than PCA for pre harvest forecasting of rice crop yield.

CHALLENGES IN DRUM SEEDING OF WET SEEDED RICE FOR SUSTAINABILITY IN EAST UTTAR PRADESH

KARAMITABHA *, RAO A.P.** & KANNAUJIYAS.K.***

Agricultural Engineering) KVK, Jaunpur, NDUAT, Faizabad

Rice being staple food, cultivation of rice has been unavoidable for the farmer in east Uttar Pradesh. The simple technique for rice cultivation commonly adopted by the farmers is nursery raising and thereafter transplanting. Both the processes water, labour, space as well as more time in order to get more production per hectare. There had been many techniques which prove to be used for getting higher yield. The farmers of east Uttar Pradesh are migrating fast to bigger cities due to unprofitable farming thus vacating villages in search of job. Therefore in order to increase farmers income for sustainability, it becomes essential to introduce those technological practices which are eco-friendly and cost saving too. Zero till machine sowing is useful for larger holdings and covers about 1.5-2 hectare depending on the size, speed of tractor, ambient temperature and moisture availability in the field. However for small and marginal farmers drum seeder is definitely helpful to sow paddy directly without much effort and within a short time. Good results have been achieved in farmers field in few districts of Uttar Pradesh where the drum seeder is being used. The paddy yield is more due to more tillers and cost of production is reduced drastically.

Key words: ambient temperature, drum seeding, eco-friendly, tillers, production, yield

LOWERING IN THE GREEN GOLD- BETEL VINE (*PIPER BETLE* L.)

KARTHIK, C. S.¹ AND VENUGOPAL, S.²

Department of Plantation, Spices, Medicinal and Aromatic Crops, Faculty of Horticulture, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, West Bengal, India. Department of Plantation, Spices, Medicinal and Aromatic Crops, Sri Konda Laxman Telangana State Horticultural University, Rajendra Nagar, Telangana, India.

Betel vine (*Piper betle* L.) is a dioecious, evergreen creeper belonging to the family *Piperaceae*. It is native to Central and Eastern Malaysia and grows in moist tropical and subtropical regions of different countries such as China, Thailand, Philippines, India, Bangladesh, Sri Lanka and etc. In India, it is cultivated in an approximate area of 45,000 ha as cash crop and West Bengal is the largest producer of betel leaf with sixty-six per cent of total production. Everyday about 15-20 million people in the country consume betel leaves. Betel leaves have many medicinal properties and are used in Indian system of medicine to cure indigestion, stomach ache, diarrhoea, flatulence and to heal wounds, scales, burns, swelling and etc. Cultivation of betel vine is broadly divided into three major types viz. Gachh pan system, open system, semi-closed or closed system and a combination of these. Lowering of vine is one of the critical and important inter cultural operation in betel vine cultivation which is done when the growth of the vine is rapid during rainy season. Tying is also done at an interval of 20-30 cm when the vines trail up to a height of 2.0-2.5 m and touch the roof of the system, they are untied from the support and lowered down to the ground level by harvesting the lower leaves, keeping 4-5 leaves at the top. The stems which accumulate at ground level are sometimes covered with soil or allowed to remain coiled on the ground between the rows and sticks. This entire operation is known as 'lowering of vines' and in certain areas manuring is usually done after every lowering.

EFFECT OF DIFFERENT FEEDING COMPOSITION ON MILK PERFORMANCE OF MURRAH BUFFALO

KARTIK TOMAR, MANOJ KUMAR, HARENDER

Department of Animal Husbandry, SVP University of Agriculture and Technology, Meerut (250110)

The present study has been done to evaluate the effect of various feed composition on milk yield of Murrah buffalo in Muzaffarnagar district of Uttar Pradesh. The objective of this study was to compare the performance of lactating buffaloes under traditional feeding system and feeding of Total Mixed Ration (TMR). Fifteen lactating Murrah buffaloes were divided into three groups in Randomize Block Design (RBD). Roughage and concentrate were fed separately in T1 group. Animals in T2 and T3 were fed TMR of different composition. Diet of animals consisted of paddy straw, sorghum fodder and concentrate mixture. The mean Dry Matter intake (DMI) was similar in three groups (11.51, 12.10 and 12.26 kg/d). Digestibilities of dry matter, organic matter, neutral detergent fiber and acid detergent fiber were increased in both T2 and T3 groups. The average daily milk yield was 7.25, 5.80 and 6.75 kg for T1, T2 and T3 respectively. The milk fat and total solids were higher in T2, while, and milk protein in T3 group.

Keywords: Milk yield, Total mixed ration, Dry matter intake.

WEED DYNAMICS UNDER CONSERVATION AGRICULTURE**KARTIK¹ AND ²RAJESH KUMAR² AND ³GOVIND**¹Department of Agronomy, CCS HAU, Hisar-125004, ²Department of Agricultural Meteorology, CCS HAU, Hisar-125004, ³College of Agriculture, Kaul, CCS HAU, Hisar-125004

Conservation agriculture is an ecological approach for sustainable crop production that is based on continuous minimum soil disturbance, maintaining permanent organic soil cover, and diversified crop rotations. Adoption of conservation agriculture changes weed dynamics and communities and therefore necessitates adjusting weed control methods. In conservation agriculture weeds expression, seed bank status, distribution, dispersal mechanisms, diversification, growing patterns and competition trends are complex and differ from conventional systems of agriculture. It is due to reduced tillage or no-till system of the soil and the flora that thrives in conservation agriculture. No-till systems accumulate seeds near the soil surface where they are more likely to germinate but are also exposed to greater mortality risks through weather variability and predation. It is observed that germinable seed banks under no-till decrease more rapidly than under conventional tillage. Also reduced tillage causes shift in weed flora from annuals to perennials. Soil surface temperature moderated by residue retention on soil surface and may extends the emergence of both crops and weeds. Restricted light availability, physical growth barriers and potential allelopathic effects from surface residue generally hinders the germination and growth of small seeded annual weeds. Crop rotations modify the weed dynamics due to allelopathic effect on weeds and alteration in timings of crop emergence and weed emergence and inhibition effect on growth of crop-bound weeds. Crop rotations should incorporate crops belongs to different botanical families, different nutrient requirements and required herbicides of different families for control of weeds. Other cultural practices for weed management under conservation agriculture includes alteration in date of sowing, selection of highly competitive cultivar, by adopting preventive measures, by change in plant geometry and densities, placement of fertilizers and microbial control of weeds. Integrated weed management compatible to cropping patterns and climatic conditions offers the best results in conservation agriculture.

ROCK PHOSPHATE-ENRICHED COMPOST AND MICROBIAL INOCULANTS FOR SOIL HEALTH**KASTURIKASEN BEURA*, AMIT KUMAR PRADHAN¹, GOUTAM KUMAR GHOSH², ANSHUMAN KOHLI¹ AND AJIT KUMAR PASWAN³***, ¹ Department of Soil Science and Agricultural Chemistry, Bihar Agricultural University, Sabour, Bhagalpur, Bihar-813210, ² Department of Soil Science and Agricultural Chemistry, Palli Shiksha Bhavana, Sriniketan, West Bengal-731236, ³ Krishi Vigyan Kendra, Jehanabad, Bihar-804432

Low grade rock phosphate deposits exist in India which are largely unexploited. Rock phosphate has good P content (28-30%) but cannot be put to direct use because of its poor release of plant available P. Rock phosphate can be used to improve the quality and overall efficacy of the compost which is a source of organic matter to soil necessary for sustaining its health and fertility. Microbial inoculants like mycorrhiza and beneficial soil microorganisms play a very impactful role in enhancing crop performance and maintaining soil health, which is indispensable for sustainability of agricultural ecosystems. Co-inoculation of mycorrhiza with rhizobacteria in presence of good quality enriched compost helps to enhance their efficacy and reliability for better plant performance and soil quality. Researchers have recorded higher yield, P uptake, enzymatic activity and microbial biomass carbon in soil under mungbean (*Vigna radiata*) due to addition of rock phosphate enriched composts in presence of *Aspergillus awamori*. It has also been observed that an additional positive effect of inoculation with mycorrhiza on plant biomass and soil nutrient content when closely related to colonization by microorganisms under application of biocompost. Composted low-grade rock phosphate along with organic material, phosphate solubilizing bacteria and other microbial inoculants have the potential to improve crop production and nutrient uptake. Composted rock phosphate can be a suitable alternative and viable technology to utilize low- grade rock phosphate and could be used successfully as cheaper and indigenous input for soil health sustainability.

Keywords: Rock phosphate, mycorrhiza, microbial inoculants, soil health, sustainability

SCREENING OF ADVANCED GERMPLASM OF MAIZE (ZEA MAYS) AGAINST SHOOT FLY (ATHERIGONA SOCCATA RONDANI)**KAUSHAL KISHOR, R.K. DWIVEDI, NEELAM YADAV, RAHUL**

Ph.D Scholar Deptt. of Entomology, CSA University of Agriculture & Technology Kanpur-208002

The present investigation of screening of fifty advanced **Germplasm** lines of Maize *Chilo partellus* (Swinhoe) along with three replications against shoot fly was carried out in randomized block design (RBD) at Student's Instructional Farm, Chandra Shekhar Azad University of Agriculture and Technology, Kanpur in Kharif 2016. The advanced **Germplasm** lines were screened on the basis of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

average percent dead hearts per plant at 14 and 28 days after emergence. Resistant checks viz., *Jaunpur local* and Prabal recorded significantly plant and also exhibited minimum average percentage of dead hearts.

EFFECT OF PRE & POST HARVEST TREATMENTS ON THE MANAGEMENT OF POST HARVEST LOSSES IN HORTICULTURAL CROPS

KAUSHELENDRA PRATAP SINGH, MANOJ KUMAR SINGH AND JAGRAJ SINGH

Department of Horticulture, SVPUA & T Modipuram, Meerut (U.P.) India 250110

Fruit and vegetables highly perishable in nature and they are lost their quality and nutritive value in shorter time of periods. The quality and nutritive value of these fresh commodities are reported at the time pre and post harvest due the improper handling and pre and post harvest treatments. The post harvest losses of horticultural crops in developing countries have been reported between 15 to 50 per cent with an estimated minimum of 20 per cent. Regarding individual commodities, in the case of fruits it was reported that it varies from a minimum of 14 per cent in case of apples to 100 per cent in the case of papaya. In the case of grapes post harvest losses are to the tune of 27 per cent and in the case of lime they vary from 20 per cent to 40 per cent. Post harvest management is a way to overcome these problems of losses and also to reported many other benefits. An experiment was conducted to study the pre harvest spray and post harvest dipping of fruit on shelf life and quality of papaya (*Carica papaya* L.) cv. Madhubindu was carried out at Fruit Research Station, Lalbaug and P. G. Research Laboratory, Department of Horticulture, JAU, Junagadh during 2013. There were two factors comprised of pre harvest spray i.e. water spray (S_1), GA₃ 15 ppm (S_2), Alar 500 ppm (S_3), GA₃ 15 ppm + Carbendazim 0.05% (S_4) and Alar 500 ppm + Carbendazim 0.05% (S_5) along with post harvest dipping i.e. water (D_1), CaCl₂ 1% (D_2) and Ca(NO₃)₂ (D_3). The pre harvest spray of GA₃ 15 ppm + Carbendazim 0.05% and post harvest dip in CaCl₂ 1% individually as well as their combination. GA₃ 15 ppm and CaCl₂ were found to be more effective in reducing physiological loss in weight, highest percentage of marketable fruits, highest shelf life. Similarly for biochemical parameters and organoleptic score, highest TSS, lowest acidity, highest ascorbic acid, vitamin A as well as organoleptic parameters like color, texture, taste and flavor were also found better in GA₃@ 15 ppm + Carbendazim 0.05% as per harvest spray and CaCl₂ 1% (D_1) as post harvest dip.

Keywords- Post harvest, Pre harvest, Horticultural crops.

PRECISION AGRICULTURE AS A TOOL FOR SUSTAINABLE AGRICULTURE

KAVITA BHADU^{1*}, PAYAL PATIDAR¹, KOMAL YADAV¹ AND RAKESH CHOUDHARY²

College of Agriculture, RVSKVV, Gwalior, Madhya Pradesh, India, Agricultural Research Station, Agriculture University, Jodhpur, Rajasthan, India

Agriculture is the base of Indian economy. There is need to increase the production at low cost. This is possible through adopting precision agriculture (PA) approach which controls the over use or wastage of inputs or resources by application of inputs where they are needed, and when they are needed.. PA is a management approach to the cultivation of crops by considering spatially and temporal variation in soils, rainfall and adopting management techniques to reduce cost, efficient use of inputs and reduce environmental pollution. Three basic principles of PA includes (1) understanding the variability in time and space, (2) measuring and assessing the variability and (3) managing the variability with site specific agronomic recommendations. PA also termed as spatially variable crop production or site specific management. By using site-specific knowledge, PA can target rates of fertilizer, seed and chemicals for soil and other conditions. The site specific application of inputs such as seed, fertilizer and crop protection chemicals has the potential to reduce input costs, maximize crop yield and benefits the environment. PA can help in managing crop production inputs in an environment friendly way, thus PA promotes sustainable agriculture.

Keywords : Precision Agriculture (PA), site-specific, environment, spatially and temporal variability.

EFFECT OF INTEGRATED WEED MANAGEMENT PRACTICES ON YIELD AND WEED DYNAMICS IN SOYBEAN + PIGEONPEA INTERCROPPING SYSTEM

KHAZI G.S.^{1*}, KARLE A.S.², ASEWAR B.V.³, PATIL V.D.⁴ AND TAMBOLI N.M.⁵

Department of Agronomy, College of Agriculture, Vasant Rao Naik Marathwada Krishi Vidyapeeth, Parbhani, 431 402, Maharashtra,

A field experiment was conducted during 2015-16 and 2016-17 at Experimental Farm, Department of Agronomy, College of Agriculture, Vasant Rao Naik Marathwada Krishi Vidyapeeth, Parbhani to study the effect of integrated weed management practices on crop and weed parameters. The soil of the experimental site was clayey in texture. pH was 8.0, low in available Nitrogen (160.7 kg/ha), medium in Phosphorus (11.7 kg/ha) and high in potassium (489.61 kg/ha). The experiment was laid out in randomized block design with

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

three replications and ten different treatments. Results revealed that the minimum weed growth rate, density and dry matter production of weeds and the higher weed control efficiency were recorded with pre emergence application of Pendimethalin 30% EC @ 0.75 kg a.i./ha fb tank mix POE - Imazethapyr 10% SL @ 0.100 kg a.i./ha + Quizalofop ethyl 10 EC @ 0.075 kg a.i./ha supplemented with 1 Hoeing (40-50 DAS). The highest Soybean Equivalent Yield were obtained with the application of PEPendimethalin 30% EC @ 0.75 kg a.i./ha +1 Hoeing (30-40 DAS) + 1 Hand Weeding (40-50 DAS). The highest weed index was recorded under weedy check.

Key words: Dicot, Intercropping, Monocot, Pigeonpea, Soybean, SEY, weed.

K- MEAN DETERMINATION OF INDIAN MUSTARD GENOTYPES FOR MORPHO-PHYSIOLOGICAL TRAITS UNDER RAINFED CONDITION

KHUSHBOO CHANDRA*, ANIL PANDEY AND S.B. MISHRA

Department of Plant Breeding and Genetics, Rajendra Prasad Central Agricultural University, Pusa (Samatipur) Bihar 848125

Under rainfed timely-sown condition an experiment was conducted predominantly cultivated crop *Brassica* species in Indian mustard (*Brassica juncea* L. Czern & Coss) for Principal Component Analysis and K-mean cluster analysis studies, in Randomized Complete Block Design (RCBD) accommodating 50 genotypes, from various Rapeseed & Mustard centres located across country, randomly in three replications during Rabi 2015-16 at Tirhut College of Agriculture, Dholi, Muzaffarpur research farm. In present investigation, only first principal component (PCA1) showed maximum Eigen value and cumulatively showed 84.22% variability. Based on PCA1, PCA2 and PCA3 scores cumulatively accommodating 94.95% variability, 3-D plotted for 50 Indian mustard genotypes, covering most important traits namely AS, AB, DFF, HFS, SS¹, RV, HFPB and RL which contributed maximum towards variability. Amongst the constituted eight clusters, the cluster VIII included four genotypes, Pusa Mahak, Varuna, Pusa Bold and Rajendra suflam followed by cluster VII with nine genotypes, reflected superiority for oil content and close for various morpho-physiological traits to cluster VIII. Most diverse genetic background was reflected by Cluster VIII (Rajendra Suflam, Varuna, Pusa Bold & Pusa Mahak); followed by Cluster III (TM-2, Divya and RH0406); Cluster V (Kanti); Cluster IV (Kranti) and Cluster VII (RH0819). Divergent cross combinations suggested namely Rajendra Suflam × Divya, Rajendra Suflam × Kanti, Pusa Mahak × Divya, Pusa Mahak × Kanti, Kranti × Divya, Kranti × Kanti, Pusa Bold × Divya, Pusa Bold × Kanti, Varuna × Divya, Varuna × Kanti, Rajendra Suflam × TM-2, Rajendra Suflam × RGN 13, Rajendra Suflam × RH 0406, RH0819 × Divya and RH0819 × Kanti involved cluster VIII × III, VIII × V, VII × III and VII × V involving divergent genotypes could through recombinants and utilized in heterotic breeding. Moreover, due to superiority for most of the yield attributing traits such combinations including root parameters also could be utilized for *Brassica* genetic enhancement under rainfed conditions of Bihar.

Key words: *Brassica juncea* L., Principal Component analysis, Genetic diversity, K-Mean clustering, Eigen value

IMPROVING TRADITIONAL APICULTURE PRACTICES TO DOUBLE FARMER'S INCOME

¹KHYATI SINGH*, ²MUKESH KUMAR MEHLA

¹Department of Vegetable Science, Maharana Pratap Horticultural University, Karnal- 132001, ²Department of Soil and Water Engineering, CCS Haryana Agricultural University, Hisar- 125001

In India, farmers having marginal landholding can be benefited by secondary activity like beekeeping. Presently, it is estimated that with 25.00 lakhs of bee colonies and 2.5 lakhs beekeepers harvested around 56,579 MT of honey. The paper enlists different strategies to increase honey production, quality and to increase adoption of apiculture by farmers for commercializing beekeeping by improving current beehive structures, proper bee hive management, *insitu*-honey extraction system. Different entrances like flap entrance, rotating door entrance, manually controlled entrances and electronic adjustable hive entrances (butterfly and helical entrance design) can be used to optimize hive entrance and provide scope for promoting better traffic flow, assist in proper ventilation of hives and exclude pests. The roof design is also taken care off. Non-white colors absorb more hot sunlight, increasing difficulty for bees to keep the hive cool. So, roofs are made from galvanized iron that absorb up to about 90% and white paint only absorbs about 30% of sunlight. Elevating the rooftops of hives, switching to other materials for construction of roofs and painting hive box with lighter colors can help in keeping hives cool thus reduces the drudgery of bees to maintain hive temperature and also improve production. The *insitu*-honey extraction type hive boxes with honey extraction and filtration unit with main working parts as hive box, lobed shaft, tap, screen and filters has proved to be effective for easy and quick honey extraction method. Vents are made to keep hive cooler. Aluminum or insulating thermoplastic is used inside the hive box. The handle is rotated to extract honey which after passing through a screen and filters can be collected through an outlet. Following the given strategies and further research in this area can help in increasing honey production and quality, and thus play important role in increasing farmers income through adoption of modern apiculture.

Keywords: Bee farming, Apiculture, Bee hive design, Bee hive management, Honey extraction

EFFECT OF PLANT NUTRITION IN INSECT PEST MANAGEMENT: A REVIEW**KIRAN BALA****CSKHPKV Palampur*

Nutrition concerns the chemicals required by organism for its growth, tissue maintenance, reproduction and necessary to maintain these functions. It may determine resistance or susceptibility to pests. Among several plant nutrients, only 17 are essential for proper growth and development of plants and each nutrient plays important role in their growth. These nutrients are required by insects for their growth, tissue maintenance, reproduction and energy. They fulfill their requirements through feeding on plants. Nitrogen has positive effects on individual insect performance, probably due to deposition-induced improvements in host plant chemistry. These improvements include increased nitrogen and decreased carbon-based defensive compound concentrations. *Potassium provides high resistance against insect pests.* High levels of potassium enhance secondary compound metabolism, reduce carbohydrate accumulation and plant damage from insect pests. Phosphorus also decreases the host suitability to various insect-pests. *Secondary macronutrients and micronutrients like calcium, zinc and sulphur also reduce the pest populations.* Among mineral elements, *silicon is involved in plant resistance against insect pest damage.* The indirect effects of fertilization practices acting through changes in the nutrient composition of the crop have been reported to influence plant resistance to many insect pests. The need for more healthful foods is stimulating the development of techniques to increase plant resistance to phytophagous insects.

ROLE OF ICTS AND SMALL-SCALE AGRICULTURE IN INDIA: A SCOPING STUDY**KIRAN RANA, RUCHI RANI GANGWAR, SHWETA CHAUDHARY***Department of Agricultural Communication, G. B. Pant University of Agriculture & Technology, Pantnagar, Uttarakhand, India*

ICTs are meticulous force of change for rural and agricultural growth. It provides development solutions and have been described as one of the main enablers of poverty reduction. They are well-organized implements for reaching rural and remote communities and improving agricultural productivity (Richardson 1997). ICTs include technologies and media that capture, store and disseminate data and information, and they include tools such as video, teletext, voice information systems, radio, mobile telephony, fax and computer-mediated networks among others (Warren 2002). ICTs can speed up the extension of development services in areas such as healthcare, education and agriculture (Van Audenhoove 2003). Further, they help strengthen partnerships and provide a framework for shared learning, and have led to increased use of networked information environment and development of platforms for better sharing and exchange of information and knowledge. This has helped to achieve competitiveness (Benkler 2006). Small-scale farmers need information on improved farming practices, technical information, technologies, credit, agro-processing, markets and marketing opportunities. There are a number of emerging ICTs being applied in small-scale agriculture including:- GIS, decision support systems, precision farming, market information system, distance learning, databases, land use planning, public access facilities, mobile applications, restructuring of extension and personal digital assistants. Geographical Information System (GIS) is an information technology that links activities in the field and the office, and allows for comparisons between different types of agricultural data. Although networked information economy cannot in itself solve poverty, hunger and disease, but it provides new avenues for offering a more attractive cultural production system, tapping economic opportunity and sharing and disseminating scientific outputs and innovative linkages between farmers, scientists and researcher. Technological changes have led to social, economic and cultural transformation. Therefore, in order to benefit the rural people, extensionists are grappling with the question of how to connect ICTs to improve rural livelihoods in order to contribute towards better information exchange and access. This paper aims to discuss role of ICTs in agricultural extension work for doubling farmers' income, identified various gaps such as inadequate skills in the use and application of ICTs, inadequate human resources with the capacity to generate, repackage and digitise local content that need to be bridged to enhance skills and facilitate the exchange and sharing of information and knowledge.

Key words: ICTs tool for rural change, Enhance skills, doubling farmers' income

DEVELOPMENT OF COMPATIBLE LIGNOCELLULOLYTIC FUNGAL CONSORTIUM FOR BIODEGRADATION RICE RESIDUE IN EASTERN INDO-GANGETIC PLAIN**KIRTISOURABH***ICAR-Research Complex for Eastern Region, Patna, Bihar*

Rice straw is one of the most abundant agricultural by-products in India. In Indo Gangetic Plains of India in situ burning of crop residues is practiced by majority of farmers' which deteriorates soil and environmental quality. Fungi have the potential for lignocellulose degradation and can be used for the in situ decomposition of crop residues. It contains high amounts of cellulose and lignin. The fungal strains were isolated from naturally decomposing sites of rice residues. Seven fungal strains were isolated and later these seven fungi were used for finding out their potential for the degradation of lignin and cellulose content of rice straw. Among seven fungi

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

tested, four fungal strains showed lignocellulolytic activities. Hence, these four fungal strains were used for the decomposition of rice residue both individually as well as in various combinations. Inoculation of these lignocellulolytic fungi in rice residue accelerated the process of residue decomposition when compared to control. Significant reduction in lignin and cellulose content were observed in rice residue inoculated with mixed culture of *Aspergillusoryzae* + *Aspergillus fumigatus* + *Aspergillusniger* + *Aspergillusflavus* compared to other experiments. Mixed culture of four fungal strains reduced C:N ratio to 10:1 compared to 70:1 in paddy straw mixed with soil. It is evident from the results that the mixed culture of all the three lignocellulolytic fungi may be used for the degradation of rice residue. Hence we conclude that combination of four lignocellulolytic fungi viz., *A. oryzae*, *A. fumigatus*, *A. niger* and *A. flavus* can be recommended for the degradation of rice residues which would result in fast degradation of lignocellulosic biomass which may allow use of normal zero-till machine for timely sowing of wheat into combined harvested rice fields and avoid in situ burning of rice straw.

SMART FARMING THE FUTURE OF AGRICULTURE

KISHAN KUMAR¹, ROHIT², KAUSHIK PRASAD³, SHUBHENDRA KUMAR PANDEY⁴, PANKAJ KUMAR SINGH⁵ AND MANOJ KUMAR⁶

¹Department of Agronomy, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India, ^{2,3,6}Department of Extension Education, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India ⁴Department of Seed Science & Technology, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India, ⁵Department of Genetics & Plant Breeding, College of Agriculture, N.D.U.A &T., Narendra Nagar (Kumarganj), Faizabad (U.P.) 224229, India

The application of smart farming and related technologies such as internet of things (IOT), precision farming, robotics and software for farm management and decision making (Smart Farming Technologies, SFTs) will bring many benefits, including more efficient use of inputs and a reduced impact on the environment ("more with less"). The goal of smart farming is to meet the food requirement in future of all human being. We inventoried SFTs that are available commercially by surveying manufacturers, providers of equipment and services, and agricultural consultants. Each SFT was described in terms of where it can be applied (which crops or cropping systems, geography, farm size, crop production stage), what benefits it is expected to bring (e.g. increased productivity, increased profitability, and how readily it might be expected to be adopted). Commercially available SFTs often target larger farms, while SFTs investigated in applied research projects are applicable on smaller farms as well as larger farms. **Food production must be increase by 70% in the year 2050 in order to meet our estimated world population of 9.6 billion people.** Smart farming has become not only an option for the future, it's becoming a necessity. So the main aim of smart agriculture is to obtain maximum production per unit area and per unit time.

Keywords: Technology, precision farming, robotics and software, etc.

PROTECTED CULTIVATION OF FRUIT CROPS- A NEW TECHNOLOGY TO PROTECT FRUIT CROP FROM NATURAL CALAMITIES, BIOTIC AND ABIOTIC STRESS

***KISHORE KUMAR DAS¹; P.K YADAV²; R.S SINGH³ AND R.K NAROLIA⁴**

^{1,2&4} Department of Horticulture, Swami Keshwanand Rajasthan Agriculture University, Bikaner- 334006, ³Central institute of Arid Horticulture, Bikaner- 334006

Fruit crops are affected by different natural calamities, biotic and abiotic stress which affect the export potentiality, productivity and quality of fruits. In order to overcome disadvantages caused by local climatic conditions, and other factors (Pathogenic and non pathogenic) protected cultivation offers a great scope for production of fruits. protected cultivation is proving as a boon for marginal and small growers with limited land and water resources. It also helps in off season fruits production round the year. low cost green house is developed in many states of India like J&K, Uttaranchal, Himachal Pradesh, North Eastern states, Maharashtra and Karnataka for production of different kind of fruits. fruits crops like Peaches, strawberry, grape, cherry, apricot, Banana, guava, Plum etc. are cultivated to save the livelihoods of this zone of farmers. Therefore, it is a new height of technology adopted by the farmers to produce high quality, pest and disease free, fruits.

MARKER ASSISTED SELECTION FOR ZINC CONTENT AND YIELD IN FRENCH BEAN (*PHASEOLUS VULGARIS* L.) UNDER THE NILGIRI HILLS OF TAMIL NADU

KOHIMANOOPUR¹, M. JAWAHAR LAL² AND S. PRANEETHA³

M.Sc. (Veg. Sci.) Student, 2-Dean, College of Horticulture and 3- Professor, Vegetable Science, College of Horticulture, TNAU, Coimbatore - Tamil Nadu, India

French bean is one of the nutritionally important leguminous crop grown for its tender pods as vegetables and dry seeds as rajma. It is a major source of dietary portions, carbohydrates, fibres and micro-nutrients specially iron and zinc. A large proportion of the population

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

is at risk of zinc deficiency due to its low levels in other food ingredients. Zinc deficiency can be addressed by making it biologically available through bio-fortification. Apart from it, the vegetable having higher amount of zinc can also be included in diet. It is evident that there exist a wide variation in seed mineral zinc content in French bean necessitating the need to characterized the variability for seed zinc accumulation to meet the specific dietary needs of bean consumers. The present study was therefore, undertaken with seventy seven French bean accessions tested in RBD with three replications at Horticultural Research Station, Ooty, The Nilgiri Hills of Tamil Nadu. The study clearly revealed a positive correlation between zinc content with seed yield (0.425), seed iron content (0.422), no of primary branches (0.451), Pod weight/plant (0.646) and seed weight (0.742). Amongst the seventy seven accessions, black seed coat accessions had higher zinc content in IC 39067 accession (86.26 mg/kg) which was followed by , IC-271509, EC-271493, IC-41650 and EC-324986 accessions. Amongst forty SSR primers linked to zinc content Viz Bmd9, Bmd16, Bmd33, Bmd154, BM211 and BM170 gave encouraging results of selective amplifications. Four markers Viz. Bmd9, Bmd16, Bmd33 and BM139 were mono-morphic. The range of variation in zinc content among tested progenies was from 12.54 to 86.26 mg/kg in seed. Considerable genetic diversity among genotypes was also observed. The Seventy seven genotypes of the present study were grouped into 9 clusters, where cluster V registered more diverse genotypes. The contribution of nutrient content was more than other attributes towards genetic divergence and can be used for selecting parents from distinctly placed clusters to obtain high heterotic effects and transgressive segregants. Based on the study of genetic diversity the maximum inter cluster distance between cluster V and cluster IX indicating the possibilities of hybridization between the genotypes of these clusters for the development of high yielding varieties in frenchbean. The mean values revealed that accession No.EC- 324986, IC-311094, EC-324995 and FB - 8 for higher yield, while for higher zinc content, IC-271509, EC-271493, IC-41650 and EC-324986, accession respectively can be selected for breeding purpose. Narrow sense heritability was of an intermediate 57.5% to high 77.84% value and transgressive segregation. These results suggest that breeding for increased zinc content in the seeds of common bean can be quite successful.

BIOINFORMATICS IN CROPIMPROVEMENT

KOMAL SHEKHAWAT¹, SWARNLATA KUMAWAT², ANIL KUMAR³, BHAGWATI BARND

Swami Keshwanand Rajasthan Ageiculture University, Bikaner (Rajasthan)

Bioinformatic resources and web databases are essential for the most effective use of genetic, proteomic, metabolomic and phenome information important in increasing agricultural crop productivity. Bioinformatics are playing significant role in providing the information about the genes present in the genome of these species. These tools have also made it possible to predict the function of different genes and factors affecting these genes. The information provided about the genes by the tools makes the scientists to produce enhanced species of plants which have drought, herbicide, and pesticide resistance in them. Similarly specific genes can be modified to improve the production of meat and milk. Certain changes can be made in their genome to make them disease resistant. Key objectives for plant bioinformatics include: to encourage the submission of all sequence data into the public domain, through repositories, to provide rational annotation of genes, proteins and phenotypes, and to elaborate relationships both within the plants' data and between plants and other organisms. Bioinformatic also play role to allow efficient exploitation of plants as biological resources in the development of new cultivars with improved quality and reduced economic and environmental costs. This knowledge is also vital for the development of new plant diagnostic tools. Traits considered of primary interest are, pathogen and abiotic stress resistance, quality traits for plant, and reproductive traits determining yield. A genome program can now be envisioned as a highly important tool for plant improvement. Such an approach to identify key genes and understand their function will result in a "quantum leap" in plant improvement.

IFS WITH REFERENCE TO APICULTURE

KOMAL

Livestock Production Management, NDRI, Karnal (Haryana), India

Honey bees are social insect belonging to order Hymenoptera, family Apidae and genus *Apis*. About 20,000 species of bees are present in the world. Only 8 spp are recognized as 'Honey bees' by entomologist. The important species of honey bees are *Apis dorsata*, *Apis cerana indica*, *Apis mellifera*, *Apis florae*, *Melipona irridipennis*. **Bee keeping/Apiculture** is the maintenance of honey bee colonies, commonly in hives by humans. A location where bees are kept is called an **apiary** or "**bee yard**." Bees collect nectar and pollen from plants. Nectar is the raw material for honey preparation & pollen is a rich food for the bees and in return honey bees have been offering services to the society through ensured pollination in cross pollinated crops. The advantages of integration of beekeeping with crops is that it does not require land to be owned and rented, feed is not an issue and bee keeping does not compete for other resources needed by livestock and crops. Crops that get benefit from pollination services are mustard crop, rapeseed, sunflower, apple, pear, plum, almond, litchi, asom lemon, cauliflower, carrot, coriander, onion, pigeon pea, berseem, alfalfa, cotton, sunhemp etc. The potential benefits due to bee pollination in the form of increase in yield of various crops. Unemployed youth can start this business with minimal funds (Rs 1-2

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

lakh). Income from 100 Bee colonies is around Rs2.50- 3.00 lakh per annum. Export of honey products attracts foreign exchange. It also enrich the biodiversity, Hence bee keeping may be adopted as an enterprise by anyone after getting training on the subject.

Key words: Honey bee, *Apis*, nectar, pollination, crops, biodiversity.

ROOT GROWTH OF PHALSA (*GREWIA ASIATICA* L.) AS AFFECTED BY TYPE OF CUTTING AND ROOTING MEDIA
KRISHAN KUMAR SINGH¹ AND J.S. CHAUHAN²

¹*School of Agriculture Science, Department of Horticulture, Career Point University Kota Rajasthan,* ²*Department of Seed Science and Technology, Chauras Campus, HNB Garhwal University, Srinagar (Garhwal) 246174, Uttarakhand, India*

The aim of this study was to determine the effects of different rooting media and Type of cutting on rooting of Phalsa (*Grewia asiatica* L.) stem cuttings. *This research was conducted to Root Growth of Phalsa as Affected by Type of cutting and Rooting Media Under Garhwal Himalayas during the Rainy season 2013-14 at Horticultural Research Centre, Chauras Campus. H.N.B. Garhwal University Srinagar, Garhwal Uttarakhand, India. The experiment was laid out in Factorial Randomized Block Design (FRBD) with three main factor (Semi hardwood, hardwood and softwood cuttings) and three sub factors (Soil+Sand+FYM, Vermicompost and Soil+FYM). Results of the investigation showed that survival percentage of cutting (57.77), percentage of rooted cutting (56.66), number of primary root (14.48) and length of longest root (8.79cm) was recorded under H₂ (Hardwood cutting) with M2 (Vermicompost) rooting media.*

Keywords: Phalsa, rooting media, cutting type and rooting percentage.

VEGETATIVE PROPAGATION OF MULBERRY (*MORUS NIGRA* L.) THROUGH CUTTING
¹KRISHAN KUMAR SINGH

School of Agriculture Science, Department of Horticulture, Career Point University Kota Rajasthan

*This research was conducted to Vegetative Propagation of Mulberry (*Morus nigra* L.) Through Cutting at Horticultural Research Centre, Chauras Campus. H.N.B. Garhwal University Srinagar, Garhwal Uttarakhand, India. Stem cuttings of the plant were subjected to different treatments; IBA concentration (1000ppm, 2000ppm and 0ppm) and rooting media (Sand+FYM, Vermicompost and Cocopeat). The experiment was laid out in Factorial randomized block design and replicated thrice. In case of IBA concentration, the maximum number of sprouted cutting (7.11), average number of sprouts per cutting (5.77), length of longest sprout (8.90 cm), diameter of thickest sprout (0.71 cm), number of leaves on new shoots (8.55), survival percentage (71.11 %), rooting percentage (70.00), number of primary root (10.77), length of longest root (10.22 cm) was recorded under 2000ppm concentration of IBA. In case of rooting media, the maximum number of sprouted cutting (7.11), diameter of thickest sprout (0.54 cm), number of leaves on new shoots (8.11), survival percentage (71.11%), rooting percentage (70.00), number of primary root (8.55), length of longest root (9.11cm) was observed under vermicompost rooting media.*

Key words: Mulberry, IBA, rooting media, cutting, rooting.

INTERCROP IN SUGARCANE FOR DOUBLING FARM INCOME
K. M. SINGH, N. PRASAD S. K. VERMA AND L. B. SINGH

Krishi Vigyan Kendra, Shahjahanpur - 242001, S.V.P.U.A. & T., Meerut, U.P.

Inter cropping system is an important approach of cropping system for increasing crop yield. Plant competition is an inevitable phenomenon in intercropping system that reduces intercrop productivity. Higher productivity in intercropping system is commonly achieved by minimizing competition and minimizing complementary use of growth resources. Intercropping increases crop yield per unit area by intensifying the use of land. It does not only contribute to increase the productivity, but also increases the farm income. Intercropping is a multiple cropping practices involving growing two or more crops in proximity. The most common goal of intercropping is to produce a greater yield on a given piece of land by making use of resources that would otherwise not be utilized by a single crop. Sugarcane crop is a cash crop of western and mid plain of U.P. Sugarcane takes near about 14 months for maturing in northern plains. Keeping these views in mind Krishi Vigyan Kendra, Shahjahanpur conducted Front Line Demonstrations on intercrop in sugarcane in both planting seasons. The major area of intercrop in autumn planting covers lentil, toria, late sown mustard and potato and in spring planting covers blackgram, greengram groundnut and mentha crop. In findings the results showed that the mentha cultivation as an intercrop gave additional 78 mandays and increasing family income Rs 23400 in spring season. Potato cultivation with sugarcane found highest family labour income Rs 16800 followed by vegetable pea (Rs 15600), lentil (Rs 12600) and toria (Rs 9600) in autumn season. Finally I have concluded that Sugarcane + potato and Sugarcane + Lentil gave higher net return in autumn and Sugarcane + Mentha & Sugarcane + Groundnut in spring planting.

“CONVERSION OF TUBEROSE (*POLIANTHES TUBEROSA*) LEAVES AND BULBS WASTE INTO VALUE ADDED COMPOST UTILIZING CONSORTIUM”**KRISHAN PAL SINGH¹ AND LIVLEEN SHUKLA²***Division of Floriculture and Landscaping¹, Division of Microbiology², ICAR- Indian Agricultural Research Institute, New Delhi-110012*

Tuberose popularly known as Rajnigandha (in Hindi) occupies a prime position among commercial bulbous flower crops apart from its landscape beauty. It is commercially cultivated for utilization in different forms of cut and loose flowers trade and also for extraction of its highly valued flower spikes, bright white flowers, sweetness of blooms and delicacy of fragrance of tuberose, transform the entire area into a nectarine and joyous one. At the time of uprooting of tuberose plants and after use separated leaves and discarded bulbs and bulblets remained unused and the management of these unused flowers, cut spikes, separated leaves and bulb and bulblets become a severe problem as they are lying on roads or dumped in water bodies. Tuberose waste has a high moisture and high carbon content that attracts insects and microorganism which grow vigorously and decay the waste and leachate produced percolates into groundwater and become the cause of several water borne diseases. Therefore, a study was undertaken at ICAR-IARI New Delhi to efficiently utilize tuberose leaves and bulbs/ bulblets waste using pit method of composting with the application of effective fungal consortium consisting various efficient cellulolytic, pectinolytic, lignolytic fungi *Aspergillus clavatus*, *Aspergillus niger* and *Aspergillus awamori*. Tuberose plants waste along with substrate dried leaves mixed in 1:1 ratio was taken and 100kg total waste was added in the cemented pits.

Two treatments viz. T1 tuberose waste + Dried leaves (1:1) untreated and T2 tuberose waste + Dried leaves (1:1) + fungal inoculant treated. The results indicated that pH, EC, potassium and sulphur obtained were 7.2, 3.0, 0.1 and 0.2 respectively in untreated compost; while 7.3, 2.6, 0.5 and 0.18 respectively in treated compost. The final product after 45 days found rich in organic carbon and total nitrogen were reported to be 34.8% and 1.3% respectively in untreated compost; while 35.5% and 1.4% respectively in treated compost. The humus was 1.2% and 5% on untreated and treated compost respectively. Seed germination was reported 50% in untreated and 100% in treated compost, sowing non-phytotoxic nature of treated compost. In treated compost the cellulose activity ranged from 30 to 150 mg reducing sugar/kg dry matter/h, xylanase activity ranged from 26 to 135 mg sugar/kg dry matter/h and protease activity ranged from 89 to 160 mg/tyrosine/kg dry matter/h while in untreated compost the above activities were found 25 to 110, 22 to 120 and 80 to 132 respectively. The compost also carries aroma of tuberose flowers used. These result obtained indicates eco-friendly utilisation of tuberose waste with low cost efficient technology.

EFFECT OF *CERCOSPORA* LEAF SPOT DISEASE ON PHENOLS CONTENTS IN DIFFERENT PARTS OF FENUGREEK PLANTS**KRISHNA KUMAR¹, AKSHAY KUMAR², MANJEET KUMAR³ AND POPIN KUMAR¹***Department of Plant Pathology¹/ Department of Entomology², Department of Vegetable Science³, Narendra Deva University of Agriculture and Technology Narendra Nagar, Kumarganj, Faizabad, (U. P.) 224229, India*

Fenugreek (*Trigonella foenum-graecum* L.) is an annual legume crop belonging to the family Fabaceae which is often cultivated in regions of India, the Mediterranean region and North Africa (Acharya et al., 2011, 2010; Petropoulos, 2002). Seeds are used for the treatment of diabetes, dysentery, diarrhea and rickets. Diosgenin extracted from the seeds is used in synthesis of sex hormones. The seeds also contain a large amount of saponins and fibers that account for many health benefits. Fenugreek has neuroprotective, antimigraine, memory improving, antibacterial, antiviral and antitumor activities, because it contains a large amount of saponins, phenol, flavonoids and fibers that cause for many health fits. The healthy and infected leaves, stems and seed of fenugreek were collected in the months of March at maturity stage of crop form vegetable form, Narendra Deva University of Agriculture & Technology Kumarganj, Faizabad.

Folin & Ciocalteus phenol reagent, 2.0 The healthy and infected plant parts viz. Leaves, stem, seed and pods were directly selected from the field for the estimation of total phenol. One gram of dried sample was weighted, cut in to small pieces and then placed in smearing methanol until the green colour was extracted. Leaves tissues were homogenized after decanting the methanol. These homogenized tissues were again boiled in methanol for further 5 minute and then filtered. Residual material was washed with 80% acidified (0.1HCL conc.) methanol. Methanol was evaporated using a rotavapour and the aqueous layer was collected to adjust the final volume as ml/g of weight with distilled water. The aqueous portion of the extract was then washed with n-hexane to remove the green colour. Total phenols were estimated using Folin- Ciocalteu reagent, according to the modified method. Place the tubes in boiling water for one minutes allowed to cool and measured the absorbance at 550nm against a reagent blank. The standard curve was prepared using different concentration of catechol. The absorbance is measured in a spectrophotometer at 550 nm. **Calculation** From the standard curve find out the concentration of phenols in the test sample and express as µg phenols/g material. The total phenols are calculated by the following formula.

$$G.F. \times O.D. \times \text{Total volume}$$

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

$$\text{Total Phenol } (\mu\text{g/g}) = \frac{\text{Aliquot taken} \times \text{Weight of sample} \times 1000}{\text{G.F.} \times \text{O.D.}}$$

G. F. = Graph factors

O.D. = observance density

The organic treatment increased the total phenol content in all plant parts. The increase was higher in healthy plant leaves (9.0 to 12.24 $\mu\text{g/g}$) in comparison to infected leaves (6.89 to 10.29 $\mu\text{g/g}$), stem (8.08 to 9.51 $\mu\text{g/g}$), pods (6.51-10.08 $\mu\text{g/g}$) and grain (3.35-6.38 $\mu\text{g/g}$). The total phenol content in healthy leaves found highest in seed treatment with cow urine (12.24 $\mu\text{g/g}$) followed by seed treatment with Vanaspativash (11.47 $\mu\text{g/g}$), seed treatment with panchagavya (11.39 $\mu\text{g/g}$), foliar spray with cow urine (11.47 $\mu\text{g/g}$) and seed treatment with cow dung slurry (10.08 $\mu\text{g/g}$). In infected leaves, it was maximum 9.29 μg in Vanaspativash, 9.48 μg in foliar spray of cow dung slurry and 9.34 μg in seed treatment with Vanaspativash. In case of stem, maximum phenol content was recorded in seed treatment with cow urine (9.51 μg) followed by foliar spray of cow dung slurry (9.44 μg), seed treatment with panchagavya (8.72 μg) and foliar spray of panchagavya (8.43 μg). Whereas in grain, total phenol content was significantly higher in seed treatment with cow urine (6.39 μg), foliar spray of panchagavya (5.50 μg), foliar spray of cow dung slurry (5.34 μg), foliar spray of cow urine (5.13 μg). In other treatment effect was not significant in comparison to control.

POST HARVEST STRATEGY: IMPROVEMENT FOR THE STORAGE QUALITY

KULDEEP KUMAR CHNANIYA* KULDEEPPAWAN KUMAR*****

Department of Horticulture ,College of Agriculture, SKRAU, Bikaner- 334006 (Raj.), Department of Horticulture (Fruit science) SHUATS-Allahabad- 211007 (U.P.), Department of Soil Science, College of Agriculture, SKRAU, Bikaner- 334006 (Raj.)

Post harvest diseases cause considerable losses to harvested fruits and vegetables during transportation and storage. Post harvest losses due to diseases, conservative estimates place losses to fruits and vegetables from spoilage. However, as harvested fruits and vegetables are commonly treated with fungicides to retard postharvest diseases, there is a greater likelihood of direct, human exposure to them than to other pesticides that are applied solely to protect foliage. There is clearly an urgent need to develop new and effective methods of controlling post harvest diseases that are perceived as safe by the public and pose negligible risk to human health and the environment. Synthetic fungicides are primarily used to control postharvest decay loss. However, the recent trend is shifting toward safer and more eco-friendly alternatives for the control of post harvest decays. Biological control has emerged as one of the most promising alternatives to chemicals. The microbial antagonists may have a greater potential for success when applied postharvest. Field application of biocontrol agents may enable early colonization of fruit surfaces, thus protecting from these infections. Moreover, pre-harvest applications can be an appropriate strategy for fruits and vegetables subject to damage in postharvest handling. Genetic engineering may also provide a useful tool in the enhancement of the biological control efficacy.

Keywords:- antagonist, Synthetic fungicides, Genetic engineering.

SITE SPECIFIC NUTRIENT MANAGEMENT IN SUGARCANE

KULDEEPSINGH AND KARTIK

Department of Agronomy, CCSHAU, Hisar-125004

Sugarcane is an important commercial crop in the tropics and subtropics (35° N to 35° S) grown for sugar purpose on a variety of soils. Global production of sugarcane was 1.88 billion tonnes in 2015. Brazil ranks first (39.5%) followed by India (18.7%). India achieved production of 362 million tonnes in 2014-15. Sugarcane being a heavy feeder crop, balance fertilization is required for getting higher yield. The low yield of sugarcane being obtained due to the imbalanced nutrient application. For achieving a definite target yield of a crop, certain quantity of nutrients must be applied to the crop and this requirement of nutrients can be calculated by considering the availability of soil inherent capacity to supply nutrients and fertilizer nutrients for total uptake. This forms the basis for the fertilizer recommendation for targeted yield of crops. The nutrients managements of sugarcane crop requires a new approach, which enables adjustments in applying N, P and K to accommodate the field specific needs of the crop for supplemental nutrients. The site specific nutrient management (SSNM) provides an approach for need based feeding of the crops with nutrients. The SSNM approach aims at increasing farmer's profit by achieving the goal of maximum yield of crop. The opportunity for maximum economic yield and improved sugar recovery was ensured through application site specific nutrient management as it helps in better growth of yield and it's attributing characters like single cane weight, number of millable cane, number of internodes, cane length, cane girth and tillering in sugarcane. The increase in the cane weight was due to increase in the number and the length of the internodes. The SSNM provides the judicious use of nutrients with better efficiency and reduces the loss of nutrients which includes leaching and volatilization losses in compared to conventional application of fertilizer.

PHYTOPHTHORA DISEASES: A CURSE FOR CITRUS INDUSTRY**KULDEEPSINGH, R. M SHARMA, O. P. AWASTHI, SUNIL KUMAR, GURURAJ M. AND PRADEEP KUMAR***Division of Fruits and Horticultural Technology, Indian Agricultural Research Institute, New Delhi-110 102*

Citrus is the third most important fruit crop of India with 13.7% production share next to banana and mango (NHB 2017). In spite of favourable soil and climatic conditions, productivity of citrus fruit in our country is very low (10.94 MT/ha) as against Indonesia (35.60 MT/ha) and in Turkey (28.99 MT/ha). Many biotic and abiotic factors have been reported to be the cause for low citrus productivity in our country. Among biotic factors, *Phytophthora* species (most importantly *P. nicotianae*, *P. citrophthora* and *P. palmivora*) are considered one of the most serious soilborne problems leading to considerable losses (10-30%) in citrus growing areas worldwide. It causes damping-off of seedlings, root and crown rot in nurseries, foot rot and fibrous root rot, and gummosis in the orchards. In central India, more than 20% citrus seedlings die due to *Phytophthora* in citrus nurseries where 7-9 million citrus plants are propagated annually. In foot rot, infection occurs on the bark near the ground level and produce lesions on the trunk or crown roots that can girdle and kill the tree. *Phytophthora* spp. infection on root cortex decays fibrous roots of susceptible rootstocks that causes decline and yield losses. Association of *Phytophthora* with other pathogens i.e. *Phytophthora-Diaporthe* (PD) complex and with the Huanglongbing (HLB) have also been reported to enhance damage symptoms. Management of *Phytophthora* requires an integrated approach as some *P. nicotianae* strains have developed heritable fungicide resistance. Control through essential oils, hypovirulent isolates of *P. nicotianae* and other biocontrol agents have shown success to some extent under laboratory and greenhouse conditions, but are difficult to commercialize. Integration approach like cultural practices i.e. production of disease-free nursery stocks, use of resistant rootstocks and irrigation management and chemical measures. Selection or breeding for *Phytophthora* resistance rootstock is considered to be the most efficient approach to managing this pathogen. This paper deals with the causes and management of *Phytophthora* rot in citrus.

FLOW ACCURACY OF EXISTING FLUTE DIAMETER (10 MM) FEED ROLLER FOR HIGH SPEED SOWING OF SOYBEAN**KUMAR MAND SHANIR K***Scientist, Agricultural Mechanization Division, ICAR-CIAE, Bhopal-462038*

The flow accuracy of existing fluted feed roller for high speed drilling of soybean was studied. In this study a 10 grooves fluted roller of 49 mm diameter, 10 mm flute diameter and 40 mm exposure length was tested for soybean seeds (JS-9560). In this study flow accuracy was measured at four fluted roll speed i.e. 20, 30, 40 & 50 rpm and three position of width of slot between the roller and the bottom plate of the feed unit (WS) at full exposure length of the rollers. In conclusion, fluted roll speed had a significant effect on the flow evenness. The metering mechanism can be used as a high speed metering mechanism. In this study, the best values for the seed flow accuracy were obtained for the flute speed of 50 rpm and WS at position 3.

Key words: Soybean seed, fluted roller, flow accuracy, CV.**EFFECT OF MULTITIER CROPPING SYSTEM IN IMPROVING SOIL HEALTH****KUMARI BEAUTY¹ AND VIJAY KANT SINGH²***¹Department of Silviculture and Agroforestry, Birsa Agricultural University, Jharkhand, ²Department of Soil Science, University of Agriculture and Technology, Pantnagar, Uttarakhand*

Multitier cropping system is an approach to increase land productivity in low-external-input, resource-limited situations. These systems have been developed over long periods of time based on agro-ecological conditions, plant diversity, farmer resources and needs. Multitier cropping system involved combination of plants with various morpho-phenological features to maximize the natural resource use efficiency and enhanced total factor productivity. It is self-sustainable system where solar energy can be harvested at different heights; soil resources are used efficiently and can increase cropping intensities. The system consists of three main components viz. main crops, filler crop and intercrops which occupy three different tiers in space of the production system. To ensure sustainable productivity and high returns from underutilized and stressed lands and to improve the soil characteristics multi-storey cropping system have been found successful in tropical rain forest, semi-arid and dry land conditions. Better utilization of natural resources i.e. water, nutrients, air, light, above and below ground space are the prime benefits of multitier cropping system along with improving nutrient cycling, enhancing soil water balance and reducing soil erosion. The presence of trees at different strata helps to conserve the soil moisture and prevent transpiration. At the same time the litter fall from different species helps in the soil enrichment. The different stories (above ground) of multitier system utilize light at different levels and thus make it available up to ground level story. Likewise, the root architecture under multitier system is effective to utilize the water and nutrients at different soil depths. So, the system provides opportunity to grow cereals

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

as ground story and small to medium fruit tree as middle story and forest tree as top story. An additional story along the border of the field serves as surplus and can be used for fodder purpose. Thus, the multitier cropping system is the system by which natural resources are utilized efficiently to enhance productivity of main crops (15-20%) and high revenue realization per unit area (50-90%).

Keywords: Morpho-phenological, root architecture, soil enrichment.

EMBRYO RESCUE TECHNIQUE AN ALTERNATIVE TECHNIQUE OVER CONVENTIONAL BREEDING IN GRAPES KUNZANG LAMO

Division of Fruit Science, PAU, Ludhiana, Punjab 141004, India

Grapes are one of the most important fruit crops of the world. It has undoubtedly become the most lucrative fruit crop of the world with substantial increase in area of its cultivation. Grape is now bred for different purposes viz., table or dessert type, juice, wine, raisin, etc. besides these, grapes also contains ample amount of antioxidants like 'resveratrol', which has been positively linked to cure cancer, heart disease, degenerative nerve disease and viral infections. So, development of high yielding cultivars of good quality and large berry size are major objectives of grape breeding programmes in order to meet the market demand. In seedless grape fertilization takes place but embryo and / or endosperm development stops soon after anthesis and seeds abort at different stages of growth, which mainly depends upon the genotypes selected through the process of sternospermocarp. Furthermore, seed abortion occurs after fertilization primarily because the endosperm fails to develop properly. Therefore, Embryo rescue technique besides to its wide range of applications is used to overcome this problem and many researchers has reported that, this technique is a reliable technique in grape breeding. Generation of F1 through conventional breeding has resulted into very low success and time consuming. By using this technique, the percentage of seedless individuals in F1 population has raised up to 44.94%. Breeding novel grape cultivars through embryo rescue is still a challenging and long-term task, which requires persistent effort of grape breeders. Genotype, sampling/inoculation time and medium are the most crucial and well-studied factors affecting the success of grape embryo rescue. Besides, other factors, such as the culture methods and utilization of plant growth regulators are also important for grape embryo rescue. Thus far, embryo rescue was extensively applied in rescuing inherently weak grape embryos, breeding seedless grapes and triploid grapes, and distant hybridization between different Vitis species. Although grape embryo rescue has been widely investigated, the development of improved cultivars is few. Further, the efficiency can be improved by optimizing the concentration of growth regulators and other vitamins.

SOILLESS CULTURE: A NOVEL APPROACH FOR AGRICULTURE DEVELOPMENT

KUSUM PANDEY¹ AND K.G. SINGH²

Deptt. of Soil and Water Engineering, Punjab Agricultural University, Ludhiana, Punjab, India., Deptt. of Soil and Water Engineering, Punjab Agricultural University, Ludhiana, Punjab, India.

Soil is usually most available growing medium for plant and it provides support, air, water and nutrients for plant growth. However, it has created some limitations for plant growth, at times. Some of them are presence of disease causing organisms and nematodes, unfavourable soil compaction, undesirable soil reaction, degradation due to erosion, poor drainage etc. Further, continuous cultivation of crops has resulted in poor soil fertility. Under such circumstances, soil-less culture can be introduced as a viable and successful alternative. Soilless culture is a broad term that includes all techniques for growing plants in solid media other than soil (substrate culture) or in aerated nutrient solution (water culture). It is a method of agriculture that grows plants without soil using a mixture of water and nutrient salts, commonly called a nutrient solution. There are various techniques of soilless agriculture have being recently used such as hydroponics, aquaponics and aeroponics. Soilless culture offers opportunities to provide optimal conditions for the growth of the plants and therefore, higher yields can be obtained compared to open field agriculture. These techniques use approximately 70-95% less water than soil cultivation. Keeping in it view, this study explores the applications of soilless cultivation technique and to reveal its future importance. For popularization of soilless culture at global level, it is very imperative to provide scientific proven technology to gardeners and create mass awareness in potential areas at global level.

EFFECT OF CERTAIN NATURAL PRODUCTS AGAINST *MACROPHOMINA PHASEOLINA* (TASSI) GOID. CAUSING DRY ROOT ROT IN SUNFLOWER"

L. DARWIN, CHRISTDHAS HENRY, N. KAVIARASAN & K. GANESH SARAVANAN

Department of Plant Pathology, Faculty of Agriculture, Annamalai University, India.

Sunflower (*Helianthus annuus* L.) is an oilseed crop characterized with its short growing period, high yield potential, is being attacked by many fungal and bacterial diseases among which charcoal rot of sunflower is economically very important. Natural products like

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

panchakavya mixture (15%) conc. totally inhibited the radial growth of the fungus, whereas turmeric powder extract and hydrated lime extract (25%) totally inhibited the mycelial growth of the *M. Phaseolina*. In pot trial studies, panchakavya mixture followed by turmeric powder were found significantly superior over control in respect of reduced disease intensity and increased yield attributes. Total and ortho-dihydroxy (OD) phenolic content was profoundly influenced by natural product treatments when compared to control.

Key words: Paanchakavya, ortho-dihydroxy phenols, hydrated lime.

EFFECT OF BIOFERTILIZERS ON SOIL HEALTH AND PRODUCTIVITY OF WHEAT (TRITICUM AESTIVUM L.)

¹LALI JAT, ¹N.S.RANA, ¹R. K. NARESH, ²AKANSHASINGH, ²DRISHTY KATIYAR

¹Department of agronomy, ²Department of soil science

Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut-250110, U.P., India

A field experiment was conducted during kharif season of 2017 on clay loam soil to study the effect of inorganic fertilizer and biofertilizers on soil fertility, yield and quality of wheat. On the basis of one year field experimentation, it can be concluded that under agro-climatic condition of U.P., application of npk fertilizer + Liquid biofertilizer is the better option for realizing higher productivity, content and uptake of nutrients and net returns of wheat and it is the better option for improved fertility status of soil with good soil health. Seed inoculation with liquid biofertilizer significantly increased the number of ears plant⁻¹, number of seeds spike⁻¹, seed, straw and biological yield, N, P, K, Cu, Zn, Fe and Mn content and uptake by seed and straw, number of total microbial population and net returns.

SOIL ORGANIC CARBON FRACTIONS AND SOIL MICROBIAL BIOMASS CARBON IMPACTED BY CROP ROTATIONAL DIVERSITY AND CONSERVATION TILLAGE

LALI JAT, ¹R. K. NARESH, ¹N.S.RANA, ¹RICHA TIWARI, ²PREMAHIER, ²MANJU VERMA

¹Department of agronomy, ²Department of Horticulture, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut-250110, U.P., India

Fractionation of soil organic carbon (SOC) is crucial for mechanistic understanding of soil organic matter decomposition and stabilization processes. It is often aimed at separating the bulk SOC into fractions with varying rates, but a comprehensive comparison of methods to achieve this is lacking. Tillage systems can change soil organic carbon storage (SOC) with soil depth and a significant accumulation at 0-20 cm depth. Across treatments, aggregate-associated C at a depth of 0-10 cm was higher in the conservation tillage than in the conventional tillage treatments. Soil total organic carbon (TOC), microbial biomass carbon (MBC), EOC, dissolved organic carbon (DOC) and labile organic C (LOC) fractions contents were significantly affected by soil depth. At 0-7 cm depth, soil MBC was significantly higher under plowing tillage than rotary tillage, but EOC was just opposite. Rotary tillage had significantly higher soil TOC than plowing tillage at 7-14 cm depth. However, at 14-21 cm depth, TOC, DOC and MBC were significantly higher under plowing tillage than rotary tillage except for EOC. Compared with conventional intensive tillage (CT) and no tillage (NT) treatments increased MBC by 11.2%, 11.5%, and 20%, and DOC concentration by 15.5%, 29.5%, and 14.1% of bulk soil, >0.25 mm aggregate, and <0.25 mm aggregate in the 0-5 cm soil layer, respectively. The importance of clay and silt sized particles (< 50 µm) for SOC stabilization was also confirmed. Particle size fractionation significantly outperformed aggregate size fractionation, due to the fact that larger aggregates contain smaller aggregates and organic matter particles of various sizes with different rotation diversity. In surface soil, the maximum (19.2%) and minimum (8.9%) proportion of total aggregated carbon was retained with >2 mm and 0.10-0.05 mm size fractions, respectively. Conservation agriculture practices secure good soil health by improving soil aggregation (53.8%) and increased energy output with respect to the conventional tillage.

Keywords: Microbial biomass, Conservation tillage, Organic matter dynamics

EFFECT OF DIFFERENT SOWING DATES AND VARIETIES ON THE GROWTH AND YIELD OF MAIZE.

1* LALIT KAKKAR 2 POONAM PANDURANG SHETE

Department of Agronomy, School of Agriculture, Lovely Professional University, Phagwara, 144411 Punjab, India, Assistant Professor, Department of Agronomy, Lovely Professional University, Phagwara, 144411, Punjab, India

Maize is a tropical grass that gets well adapted to many climates and hence has wide-ranging maturities from 70 days to 120 days. Maize plants are erect and may grow as tall as 3m, with little tillering capacity. The scientific name of Maize is *Zea Mays*, also commonly known as Corn. The main aim of this research is to test the hypothesis that the impact of different dates of sowing on crop growth and yield of Maize. Best sowing dates provide favorable temperature to obtain maximum yield. Three varieties of Maize Pioneer P1844, Dragon

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

NMH (NUZIVEEDU seeds), Swarn were selected and cultivated in Phagwara belonging to Punjab region. Early and late sowing is done to grow the Maize crop of different varieties at 10 days interval. Early sown crop mature early than those sown later. Early sown crop reduced from the different types of injuries like drought and diseases other environmental factor like rainfall, temperature humidity Dose of fertilizers like UREA AND DAP are used in 27 plots to enhance the yield and growth of Maize. On the behalf of this research work we conclude that the different dates of sowing like early sowing and late sowing give crop growth and yield of Maize.

KEYWORDS: Crop; Maize; Variety; treatment; fertilizer.

IN-VITRO EVALUATION OF FUNGICIDES, PLANT EXTRACTS AND BIOAGENTS AGAINST *MACROPHOMINA PHASEOLINA* (TASSI) GOID THE CAUSAL AGENT OF DRY ROOT ROT OF CHICKPEA

LALITA LAKHRAN¹, R.R. AHIR², MEERA CHOUDHARY¹ AND PURSHOTTAM BIJARNIYA¹

In recent years cultivation of chickpea has been decreases due to major constraint of root rot disease. Chickpea (*Cicer arietinum* L.) also known as Bengal gram is one of the most important winter season pulse crop grown in India. The efficacy of various plant extracts and fungicides were evaluated against *Macrophomina phaseolina* (Tassi.) Goid causing dry root rot of chickpea. Six phyto extracts were evaluated *in vitro* by poisoned food technique against *M. phaseolina*. The extract of garlic cloves (*Allium sativum* L.) was proved excellent with maximum inhibiting (70.15 and 100 %) mycelia growth followed by Neem leaf extract (*Azadiracta indica*) (68.35 and 82.35 %) at 5 and 10% respectively. The fungicides were tested against *M. phaseolina* by poisoned food technique *in vitro*. Significantly maximum mycelium inhibition was recorded in Carbendazim (100%) followed by Carbendazim+ Mancozeb. Among bioagents tested, maximum inhibition was recorded in (*T. viride*) (80.20%) followed by *Trichoderma harzianum* (65.10%) compared to control.

KEYWORDS: bio- agents, fungicides, *Macrophomina Phaseolina*, plant extract, Root rot,

EFFECTS OF FRAME STRENGTH ON THE COMB AREA DAMAGE BY GREATER WAX MOTH, *GALLERIA MELLONELLA* IN STORED COMBS AND ITS CORRELATION WITH WEATHER PARAMETERS AT HISAR

LALITA*, YOGESH KUMAR

Department of Entomology, CCS Haryana Agricultural University, Hisar India -125004

Experiment was carried out at Research farm of the Department of Entomology, Chaudhary Charan Singh Haryana Agricultural University, Hisar to examine the damaged area of combs. The damage area of combs (cm²) caused by *G. mellonella* larvae in stored combs of different frame strength (7, 8, 9 10 frame/ hive body) was recorded from June to October 2016 and 2017. Mean area damage was recorded highest in hive body having 10 frames (121.69 cm² and 123.94 cm²) followed by 9 frames (106.21 cm² and 108.14 cm²) and 8 frames (94.81 cm² and 97.33 cm²) while lowest was recorded in 7 frames (81.37 cm² and 83.42 cm²), respectively in year 2016 and 2017. Irrespective of the different frames strength, damaged area was found highest (195.11 and 172.00) in September followed by October (150.50 and 105.89), August (133.30 cm² and 113.95 cm²), July (77.94 cm² and 29.32 cm²) and June (19.35 cm² and 12.90 cm²) respectively, in 2nd and 1st fortnight except in October (1st and 2nd) during year 2016. Same trends were also observed in year 2017. There was a highly significant difference found between the time interval of different month and frames strength in the occurrence of damaged area. The correlation study indicated significant positive correlation of extent of damage with maximum temperature (r = 0.703 and r = 0.704), maximum humidity (r = 0.227 and r = 0.222) and negatively non-significant with minimum temperature (r = -0.512 and r = -0.475) and minimum RH (r = -0.267 and r = -0.315) respectively, in year 2016 and 2017.

Keywords: stored combs, *Galleria mellonella*, frame strength and area damage.

INTEGRATED PEST MANAGEMENT AGAINST RHINOCEROS BEETLE IN COCONUT

LAXMI KALYANI RATNALA¹ AND KARTIK PRAMANIK²

M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Horticulture, M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha

Coconut *Cocos nucifera* L. is one of the important plantation crops of tropical world grown in more than 93 countries and supports the livelihoods of millions of people. In India, it is predominantly cultivated in coastal states and Islands. The Rhinoceros beetle *Oryctes rhinoceros* L. is an important pest reported from all the coconut growing countries of the world. Intensive agricultural practices relying heavily on chemical pesticides are a major cause of wide spread ecological imbalances resulting in serious problems of insecticide resistance, pest resurgence and pesticide residues. There is a growing awareness world over on the need for promoting environmentally

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

sustainable agriculture practices. Integrated Pest Management (IPM) is a globally accepted strategy for promoting sustainable agriculture. IPM as a holistic approach of crop protection based on the integration of multiple strategies viz., cultural, physical, mechanical, biological, botanical and chemical. Over the years IPM underwent several changes, shifting its focus from damage boundary, economic injury to economic threshold. Hence IPM has been evolving over the decades to address the deleterious impacts of synthetic chemical pesticides on environment ultimately affecting the interests of the farmers to control rhinoceros beetle and enhance yield.

Keywords: IPM, Coconut and control.

ALLELOPATHIC EFFECTS IN PLANTS

¹LEITAM NEKHANPRIYA, ²SATYAJYOTI THONGBAM, ²ABHISHEK ANEJA

¹Department of Horticulture, ²Department of Agronomy, School of Agriculture, Lovely Professional University

Allelopathy refers to the advantageous or damaging effects of one plant on another plant, both crop and weed species, from the release of bio-chemicals, known as allelochemicals, from plant parts by leaching, root exudation, volatilization, residue decomposition, and other processes in both natural and agricultural systems. Allelochemicals are a subcategory of secondary metabolites that are not required for metabolism i.e., growth and development of the allelopathic organism. Allelochemicals with negative allelopathic effects are an important part of plant defence against herbivorous i.e., animals eating plants as their primary food (Fraenkel 1959; Stamp 2003). Allelopathy reduces seed germination and seedling growth. Like synthetic herbicides, there is no common mode of action or physiological target site for all allelochemicals. Allelochemicals sites of actions include cell division, pollen germination, nutrient uptake, photosynthesis, and specific enzyme function. In velvet bean, 3-(3',4'-dihydroxyphenyl)-L-alanine (l-DOPA), indicated that the allelochemicals inhibition by this compound is due to adverse effects on amino acid metabolism and iron concentration equilibrium. Certain plant species releases allelochemicals into the surrounding soil to inhibit the germination and growth of other plants. This gives these plants a competitive advantage, both in the wild and on the land. Allelopathic effect can be used as a plant's advantage or to its detriment. Plant species with a stronger allelopathic ability compete with those with weaker allelopathic abilities, particularly during times when light, water, nutrients or space, were in short supply, such as during a drought.

Keywords: Allelopathy, Allelochemicals, Herbivorous

DOUBLING THE FARMERS INCOME THROUGH INNOVATIVE APPROACH

LOKESH KUMAR*, ANITA* OMPRAKASH*, NARENDRA KUMAR VERMA**

Department of Horticulture, College of Agriculture, Bikaner, SKRAU, Bikaner; Rajasthan 334006 (India), Department of Fruit Science, College of Horticulture & Forestry, Jhalrapatan, Jhalawar; AU, Kota : 324001, Rajasthan (India)

The agriculture based Indian Economy needs high agriculture income for the farmers who feed the 1.25 billion Indian population. Not only this like developed countries who despite having much lesser area under cultivation, export number of farm products, This will attract more and more people towards agriculture, the backbone of the country. The Prime Minister Narendra Modi said that his government has decided to double the farmers' income by 2022 when India would celebrate 75 years of Independence The goal is achievable if the farmers adopt and use modern technology in cultivation like drip irrigation as it will direct the maximum utilization of water with minimum quantity. The Prime Minister said "Water is like God, we have no right to waste it.". The focus will then be on "More crop per drop", "Hark khet ko pani" (water for every farm), "Doubling farmers' incomes". Laying the route map to double the farmers income, the Prime Minister said "Centre has decided to double farmers' income by 2022 by improving technology, increasing milk production, use of solar light, honey production. The NITI Aayog has already come out with its 'Three Year Action Agenda' a plan that covers a time period up to the 2019. In its chapter on agriculture titled 'Agriculture: Doubling Farmer's Incomes', the economic think-tank has put forth a 4-point action plan to double the incomes of India's farmers. A subsidy would be provided on targeted produce in case the price falls below MSP-linked threshold. One advantage of this, as highlighted by the action plan, is that it would spread price incentives to producers in all the regions and all the crops considered important for providing price support. NITI Aayog has also called for substantive investment in irrigation, seeds & fertilisers and new technology coupled with a shift into high-value commodities such as horticulture, poultry and dairying to double incomes.

EFFECT OF DIRECT SPRAY OF INSECTICIDES ON MORTALITY OF HONEYBEE, *APIS MELLIFERA* L. (HYMENOPTERA: APIDAE) ON MUSTARD CROP (*BRASSICA NAPUS*)

M. R. BAJIYA, D. P. ABROL AND SARDAR SINGH KAKRALIYA*

Division of Entomology, Sher-e-Kashmir University of Agriculture Sciences and Technology, Jammu (Jammu & Kashmir), India - 180009

**Division of Plant Pathology, SKUAST-Jammu*

The effect of direct spray of insecticides on mortality of honeybee, *Apis mellifera* L. (Hymenoptera: Apidae) on mustard crop (*Brassica napus*) cultivar DGS-1 were studied at Jammu (India). Under field conditions the application of methyl-demeton resulted in 100 per cent bee mortality within one hour of spraying followed by imidacloprid (76.5, 100 per cent), acetamiprid (55.0, 62.5 per cent), diamethoate (47.5, 59.00 per cent) and thiamethoxam (42.5, 51.5 per cent) during 2014-15 and 2015-16 respectively. However, the per cent mortality of honey bee was not observed in treatment of control. Toxicity order of insecticides were methyl-demeton > imidacloprid > acetamiprid > diamethoate > thiamethoxam. After 3 hours of spraying the mortality was 100 per cent of methyl-demeton and imidacloprid followed by acetamiprid (77.5, 80.0 per cent), diamethoate (70.0, 79.0 per cent) and thiamethoxam (50.0, 56.5 per cent) whereas no mortality was observed in control treatment. Similar trend was obtained in all the treatments but with increased per cent bee mortality after 7 hours of spraying. After 12 and 24 hours of spraying the mortality was 100 per cent for all the treatments except thiamethoxam, which recorded (99.0, 97.5 per cent) during 2014-15 and 2015-16 respectively. It is thus evident that methyl-demeton followed by imidacloprid, acetamiprid, and diamethoate were more toxic to the honey bees forager and thiamethoxam having insecticidal properties was found to be less toxic of honey bees forager. Statistical analysis of the data revealed that effects of different insecticides at different hours of treatment on mortality of bees were highly significant.

Key Words: *Apis mellifera* L., *Brassica napus*, Insecticides, Direct mortality, Pollination.

INFLUENCE OF NITROGEN PHOSPHORUS AND POTASH ON GROWTH AND YIELD OF OKRA (*ABELMOSCHUS ESCULENTUS* L. MOENCH)

M. S. RATHI, AMARSINGH AND ANIRUDHAKUMAR SHARMA

J. V. College, Baraut, Baghpat (C C S Univ., Meerut), Department of Horticulture

The present investigation was conducted at Horticulture research farm J. V. College, Baraut, Baghpat. The experiment layout carried out following randomized block design with three replications of twelve treatment combinations including check three levels of nitrogen phosphorus and potash fertilizers application. In which Okra (*Abelmoschus esculentus* L. Moench) cv. Parbhani Kranti, was used to study on growth and fruits yield response of nitrogen (55, 80 and 105 kg/ha), phosphorus (40, 60 and 80 kg/ha) and (20, 40 and 60 Kg/ha) along with having control (0, 0), these doses were applied with check. Results also indicated that, nitrogen @ 105 kg/ha phosphorus @ 80 kg/ha and 60 Kg/ha significantly reduced the number of days to 50% germination and 50% flowering and increases maximum plant height, number of branch, leaf area, number of green fruits/plant compare to other treatment of nitrogen, phosphorus and Potash of Western Uttar Pradesh.

Keys Words: Parbhani Kranti, Nitrogen Phosphorus, Potash.

IMPORTANCE OF POST HARVEST TECHNOLOGY FOR VALUE ADDITION AND PRESERVATION OF HORTICULTURE CROPS

M. SIVA, T. S. K. K. KIRAN PATRO, U. MURALI KRISHNA, KOTESWARARAO AND M. M. NAGARAJU

College of Horticulture, YSR Horticultural University, Venkataramannagudem-53410, West Godavari

Value addition is a process in which for the same volume of a primary product, a high price is realized by means of processing, packing, upgrading the quality or other such methods improve the profitability of farmers. Horticulture deals with the cultivation of crops which belong to us and possess great medicinal, nutritional, health promoting values. India as second largest producer of fruits and vegetables, only 10 per cent of that horticultural produce is processed, but other developed and developing countries where 40-80 per cent produce is value added. Horticultural crops provide varied type of components, which can be effectively and gainfully utilized for value addition like pigment, amino acids, oleoresins, antioxidants, flavors, aroma etc. Post harvest losses in horticultural produce is about 5 to 30 per cent which amounts to more than 8000 crore rupees per annum. If we subject our produce to value addition the losses can be checked. Horticultural crops are right material for value addition because they are more profitable, has high degree of process ability and richness in health promoting compounds and higher potential for export. There is a tremendous demand of novel and innovative processing and value-added products of international standards. Scope of minimal processing is also increasing with the increasing consumer demand for fresh and fresh-like foods. Nowadays people shifted to replace the use of preservatives with advanced packaging technologies and safer and healthier extraction technologies. Minimal processing and MAP and CAP, extruded fruit-based items, high pressure

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

processing, vacuum drying of fruits and vegetables, osmo dehydration technology for making fruit bars, candies, ready to serve beverages, shift from loose to packaging/effective packaging of fruits and their products, health tonic/beverages. To empower the farmers and other weaker sections of society especially women through gainful employment opportunities and revitalize rural communities. To provide better quality, safe and branded foods to the consumers, reduce post harvest losses, increased foreign exchange, encourage growth of subsidiary industries and increase farmers' financial stability.

GROWTH AND DEVELOPMENT OF *CALLOSOBRUCHUS CHINENSIS* (LINN.) ON DIFFERENT PULSE GRAINS

M.P. MAGAR, C.G. SAWANT AND P.K. NALWANDIKAR

Department of Agricultural Entomology, College of Agriculture, Latur, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani- 431 402

The present studies on the growth and development of *Callosobruchus chinensis* (Linn.) on different pulse grains were carried out at the Department of Agricultural Entomology, College of Agriculture, Latur during, 2015-2016. Result revealed that significantly shorter incubation period (4.17 days), larval-pupal period (22.21 days) and higher growth index (3.22) was recorded when *C. chinensis* reared on kabuli gram. The significantly lower egg hatch (80.00 per cent), growth index (1.71) and higher larval-pupal period (27.53 days) was observed when *C. chinensis* reared on kidney bean. The significantly higher life-cycle duration in male (32.05 days), female (32.29 days) and in general (32.17 days) was recorded on kidney bean and significantly lower life-cycle duration in male (26.31 days), female (26.45 days) and in general (26.38 days) was found on kabuli gram.

The significantly lowest percentage of adult emergence in male (26.00 per cent), female (29.00 per cent) and in general (55.00 per cent) was recorded on kidney bean. The significantly highest per cent adult emergence in male (41.00 per cent), female (44.00 per cent) and in general (85.00 per cent) found when *C. chinensis* reared on kabuli gram. The significantly highest longevity in male (8.82 days), female (8.70 days) and in general (8.76 days) was recorded when *C. chinensis* reared on kabuli gram. The significantly highest number of eggs (100.00 eggs) were laid by female of *C. chinensis* when reared on kabuli gram and lowest (64.96 eggs) by female when reared on kidney bean.

The net reproductive rate (R_0) of *C. chinensis* was 42.05, 31.34, 33.74 and 17.64 females per female per generation on kabuli gram, white tur, red tur and kidney bean, respectively. The mean length of generation (T) was maximum (33.76 days) on kidney bean and minimum (31.40 days) on white tur. On the basis of (r_m) values the descending order of food grains for *C. chinensis* was kabuli gram (0.1164), red tur (0.1120), white tur (0.1097) and kidney bean (0.085). The finite rate of increase in numbers (λ) was 1.30, 1.28, 1.29 and 1.21 females per female per day on kabuli gram, white tur, red tur and kidney bean, respectively.

On the basis of overall suitability of different pulses this indicated that kabuli gram was found to be most suitable for growth and multiplication of *C. chinensis* while, kidney bean was observed to be less suitable for the development of pulse beetle *C. chinensis*.

VERMI COMPOST & ITS SIGNIFICANCE

MACHARLA KARTHIK

Maya College, Selaqui (Dehradun)

Vermi composting is a method of using worms to transform organic waste into a nutrient rich fertilizer. It is a breaking down of organic material through the use of worms, bacteria & fungi. Vermi compost have higher level of available nutrients like calcium, nitrogen, phosphorous, potassium, carbon, magnesium derived from wastes. Wastes used include industrial, agricultural plant debris & domestic waste papers & cattle dung. Varieties of earthworms used include *Eudrilus eugeniae*, *Perionyx excavates* in vermi compost. The major advantage of vermi compost is that it can be used for all crops like agricultural, horticultural, ornamental, vegetable production at any stage of crop. Its benefit include, higher nutrient content as compared to traditional compost, improves soil structure, soil texture, aeration and water holding capacity and prevents soil erosion other main advantages as it minimises the pests and diseases in crop, and enhances the process of decomposition of organic matter in soil ideal conditions include Ph range should be between 6.5 -7.5 with moisture content of 60-70%, temperature range of 19-30 celsius is suitable for best production. This revealed that the organic waste can be converted into useable form with its excellent nutrient release. It is eco-friendly, cost effective method aimed ideal method for management and development of solid waste. It uses waste as raw material in building up of soil fertility and improving soil health for sustainable agriculture.

EFFECT OF ORGANIC, INORGANIC AND BIOFERTILIZER ON PLANT GROWTH ATTRIBUTING CHARACTERS OF CABBAGE (*Brassica Oleracea* var. *Capitata*) UNDER CHHATTISGARH PLAIN ZONE**MADANKUMAR JHA¹, BAHRTI JHA², RUDRANEE SINGH³, PASHYANTI URRAIYA⁴, MANJU RANISAHU⁵***Student of M.Sc. (Hort.) Dept. of Vegetable science, BTC CARS, Bilaspur (C.G.), Student of M.Sc. (Hort.) Dept. of Horticulture OUAT, Bhubneshwar (Odisha), Student of M.Sc. (Hort.) Dept. of Vegetable science, JNKVV, Jabalpur (M.P.), Student of M.Sc. (Hort.) Dept. of Vegetable science, JNKVV, Jabalpur (M.P.), Student of M.Sc. (Hort.) Dept. of Vegetable science, BTC CARS, Bilaspur (C.G.)*

The field experiment was conducted during Rabi season of 2016-17 at the Horticulture Research cum Instructional farm, BTC CARS, Bilaspur (C.G.). The treatments consisted of eleven combination of different agro input management practices viz., treatments 100 % RDF (Control) (T₁), 75 % RDF + 25 % N through FYM (T₂), 75 % RDF + 25 % N through VC (T₃), 50 % RDF + 50 % N through FYM (T₄), 50 % RDF + 50 % N through VC (T₅), 125% RDF (T₆), 100 % RDF + 25% N through FYM (T₇), 100 % RDF + 25% N through VC (T₈), 100 % RDF + 25% N through FYM + *Azotobacter* @ 2 kg ha⁻¹ + PSB @ 2 kg ha⁻¹ (T₉), 100 % RDF + 25% N through VC + *Azotobacter* @ 2 kg ha⁻¹ + PSB @ 2 kg ha⁻¹ (T₁₀), 100 % from organic FYM+VC+AZ+PSB (T₁₁). Significantly maximum plant height recorded 30.59 cm (T₃), 36.55 cm (T₃) and 42.47cm (T₃) at 30, 60 DAT and at harvest. The minimum plant height of 24.48 cm (T₁), 29.72cm (T₈) and 32.66cm (T₁₁) were recorded under at 30, 60 DAT and at harvest respectively. The maximum plant spread were recorded 47.27 cm (T₃), 56.13 cm (T₃) and 65.23 cm (T₃) over rest of the treatment at different stages i.e 30, 60 DAT and at harvest respectively. The minimum plant spread i.e. 37.51 cm (T₁₁), 47.28 cm (T₁₁) and 48.91cm (T₁₁) were recorded at 30, 60 DAT and at harvest respectively. Significantly Maximum **length of unfolded leaves plant⁻¹** were recorded 24.90 cm (T₂), 26.91 cm (T₂) and 31.84 cm (T₂) for different stages i.e. 30, 60 DAT and at harvest. The minimum **Length of unfolded leaves plant⁻¹** were recorded 20.10 cm (T₃), 20.50 cm (T₁₀) and 22.76cm (T₁₀) for different stages i.e. 30, 60 DAT and at harvest. The maximum **breadth of unfolded leaves plant⁻¹** were recorded 18.51 cm (T₄), 28.20 cm (T₄) and 33.38 cm (T₄) for different stages i.e. 30, 60 DAT and at harvest respectively. The minimum **breadth of unfolded leaves plant⁻¹** were recorded 14.34 cm (T₁₁), 19.30 cm (T₁₀) and 22.48 cm (T₁₀) for different stages i.e. 30, 60 DAT and at harvest. The maximum number of loose leaves plant⁻¹ were recorded 11.53 (T₅), 15 (T₅) and 15.47 (T₅) for different stages i.e. 30, 60 DAT and at harvest respectively. The minimum number of loose leaves plant⁻¹ were recorded 9.33 (T₁₀), 12.27 (T₁₀) and 12.43 (T₁₀) for different stages i.e. 30, 60 DAT and at harvest respectively

KEYWORDS: *Organic, Inorganic, Biofertilizer Combination, Azotobacter***“FERTILITY RESTORATION STUDY IN PEARL MILLET GERMLASM LINES”****MADANKAR KARTIK SAHADEO***Chaudhary Charan Singh Haryana Agricultural University, Hisar, Haryana, India*

Pearl millet [*Pennisetum glaucum* (L.) R. Br.], an annual C4 crop, is the fourth most extensively cultivated cereal in India. Discovery of male sterility system and breeding of commercially viable male sterile lines is a land mark in pearl millet hybrid cultivar development. Genetic and cytoplasmic diversification of seed and pollen parents is very much needed to avoid parents and hybrids becoming susceptible to biotic stresses. Therefore, use of diverse male sterile and restorers lines having high combining ability is very important to realize heterosis in F1 hybrids. To achieve this, differentiation of germplasm for maintainer and fertility restoration behavior is an important initial step in pearl millet breeding programs. An experiment comprised of 3 male sterile lines and 25 germplasm lines of pearl millet. The 75 hybrids were made at ICRISAT, Hyderabad and evaluation of hybrid did at Pearl Millet Research Station, Department of Genetics and Plant Breeding, CCSHAU, Hisar, Haryana. The fertility restoration ability of 25 germplasm lines on different cytoplasmic sources was studied. Among the 75 hybrids studied, 70 hybrids were complete fertile and 5 hybrids were recorded sterile. Developmental variation in the male sterile and male fertile lines of pearl millet was studied in five developmental stages viz., PMC, dyad, tetrad, soon after microspore release and before dehiscence of anther and it was found that, break down of fertility in the sterile anthers of pearl millet was post meiotic, in specific soon after the release of tetrad in the developmental stage. Identification of restorers for male sterile lines opens up new avenues in pearl millet hybrid breeding program.

Keywords: pearl millet, germplasm lines, fertility restoration.

CISGENESIS STRONGLY IMPROVES INTROGRESSION AND INDUCED TRANSLOCATION BREEDING IN PLANTS**MADHU CHOUDHARY*, VARSHA SINGH, OMESH KUMAR***Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005*

Cisgenesis represents a step toward a new generation of GM crops. The lack of selectable genes (e.g. antibiotic or herbicide resistance) in the final product and the fact that the inserted gene(s) derive from organisms sexually compatible with the target crop should rise less

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

environmental concerns and increase consumer's acceptance. The generation of a cisgenic apple plant by inserting the endogenous apple scab resistance gene Homologues of *Cladosporium fulvum* resistance genes of *Vf region* (HcrVf2) under the control of its own regulatory sequences into the scab susceptible apple cultivar Gala. In order to develop marker-free plants, the chemically inducible recombinase system in strawberry was applied to apple. Cisgenesis can be used to enhance the expression of an endogenous phytase gene in barley through the insertion of extra gene copies of the endogenous phytase gene isolated from barley itself. Phytases of the purple acid phosphatase (PAPhy's) group account for the majority of the phytases synthesized in barley. Two PAPhy types, termed *HvPAPhy a* and *HvPAPhy b*, have been identified. *HvPAPhy a* is preferentially synthesized during seed development and stored as preformed phytase in the mature grain, while *HvPAPhy b* is preferentially synthesized during germination. Gibberellic acid is a plant hormone with a wide variety of functions in controlling plant growth and development. Five different cisgenes (*GA20ox7*, *GA20ox2*, *GAI1*, *RGL 1_1*, and *RGL 1_2*) were studied, along with empty vector controls and non-transgenic controls. *GA20ox* is an enzyme that catalyzes the penultimate step in the biosynthetic GA pathway, and thus tends to promote cell division and elongation, whereas the other genes tend to repress or attenuate active GA actions.

Key words: Cisgenesis, Gene, Phytase, Resistance, Gibberellic acid.

EFFECT OF POTTING MEDIA INCORPORATED WITH PUSA HYDROGEL ON GROWTH AND PRODUCTION OF QUALITY FOLIAGE PLANTS OF *PHILODENDRON XANADU*

MADHU BALA,

Department of Floriculture and Landscaping, PAU, Ludhiana

The efficacy of potting media incorporated with different concentrations of Pusa hydro gel was tested for production of quality foliage plants of *Philodendron xanadu* at the Research Farm of Department of Floriculture and Landscaping, PAU, Ludhiana during 2016-17. Potting mixtures consisted of soil: farm yard manure: sand (1:1:1) was incorporated with 0, 10, 20, 30 and 40 g concentrations of Pusa Hydrogel/ 5 kg of potting media. The media supplemented with different levels of hydro gel resulted in significantly improved growth characters of foliage plants. Among all the levels of gel, incorporation of Pusa hydrogel @ 40 g/5 kg potting media reduced the frequency of irrigation, quantity of water required. Further, improvement in foliage quality of plants with respect to plant height, plant spread, number of leaves per plants, leaf length, leaf width and longevity of leaves were observed. The maximum plant height (42.12 cm), number of leaves (29.16), leaf area (690.23 sq. cm), plant spread (48.20 cm), leaf longevity (20.50 days) and number of primary roots per plant (8.45) were recorded in media incorporated with Pusa hydrogel @ 40 g/5 kg potting media. The minimum plant height (30.22 cm), number of leaves (16.91), leaf area (489.77 sq. cm), plant spread (33.02 cm), leaf longevity (14.58 day) and number of primary roots per plant (5.5) were recorded in control where Pusa hydrogel was not added in the potting media. The addition of Pusa hydrogel with media resulted in efficient use of water by reducing irrigation frequency and improved the quality of plants produced.

SEARCHING OF PLANT INTERACTOR PROTEIN FOR XOPC2 T3SS EFFECTOR PROTEIN OF *XANTHOMONAS AXONOPODIS* PV. *PUNICAE* CAUSING BACTERIAL BLIGHT OF POMEGRANATE

MADHVISONI AND KALYAN K. MONDAL*

Division of Plant Pathology, ICAR-Indian Agricultural Research Institute, New Delhi 110012

Bacterial blight of pomegranate, an important disease caused by *Xanthomonas axonopodis* pv. *punicae* (*Xap*), is a major threat to pomegranate cultivation. *Xap* secretes xanthomonas outer protein (xop) effectors via T3SS directly into the pomegranate cells during disease development. The T3SS effectors are mainly used by pathogen to suppress pathogen-associated molecular pattern (PAMP)-triggered plant immunity (PTI). Previously, we demonstrated the key role of XopC2 in the suppression of pomegranate immunity. Now it is pertinent to search its cognate interactor(s) in pomegranate. We employed Y2H system in identifying the interactors for XopC2 in pomegranate. Briefly, we constructed cDNA library of pomegranate in an activation domain vector pGADT7 in a way that protein encoded by the insert are fused to 3' end of Gal4 AD. The construct was transformed into Y187 strain of yeast. Similarly, bait construct was developed using XopC2 in DNA binding domain in *GAL4* DNA-BD vector pGBKT7 and transformed in Y2H gold strain of yeast. Bait toxicity was determined on different selective media along with controls. The XopC2 was observed to be non toxic to the yeast and was also not auto activating the reported genes present in the yeast. Thus the bait was direct used for identification of the plant interactor. The two stains (bait and prey) were mated and selected on selective media. After mating of two stains the interacting blue color colonies were screened confirmed using insert check PCR. The plasmid was isolated from positive and sequenced. The possible interactor(s) identified are being validated through various assays.

Key words: Pomegranate, Effectors, Xanthomonas, XopC2

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"**MUTATION BREEDING IN FRUIT CROPS****MAHANTHESHAM*¹, MAHANTESH K² NAVEEN KUMAR K L³ AND SANTOSH KORAV⁴***College of Agriculture, CCSHAU, Hisar, Haryana, India-125004, ³PhD Scholar, College of PG-Studies, CAU, Umiam 793103, Meghalaya, India*

Mutation is a sudden and heritable change of the nucleotide sequence of the genome of an organism, virus, or extra-chromosomal DNA or other genetic elements. Due to increasing the human population, reduced availability of cultivated land and climate change directly affects sustainability of fruit production. Among the various breeding methods, conventional breeding (limitations) and transgenic crops (controversies), mutation breeding is an emerging tool for developing new cultivars within a short period of time. In fruit crops, spontaneous mutation (Bud sports) are more common in citrus, grapes, etc. and induced mutation is widely adopted to bring variation and evolving new varieties or species. Mutations may result into deletion, inversion, translocation of chromosome and nucleotide base substitutions. Mutations can be induced by using mutagens (physical and chemical) such as gamma rays, X rays, EMS (Ethyl Methane Sulphonate) *etc.* Perennial nature, long juvenile phase, heterozygosity, polyploidy, parthenocarpy, seedlessness (less number of seeds per fruit), sexual incompatibilities in fruit crops limits their improvement through conventional breeding.

Key words: varieties, chromosomal aberration, mutagens, breeding methods

PEST MANAGEMENT IN ORGANIC FARMING FOR SUSTAINABLE AGRICULTURE**MAHESH KHILARI, UNDER SUPERVISION OF PROF. S.V.S. RAJU***M.Sc, Entomology And Agricultural Zoology, Institute of Agricultural Sciences, BHU, VARANASI*

Organic farming is a method of crop and livestock production that involves much more than choosing not to use pesticides, fertilizers, genetically modified organisms, antibiotics and growth hormones. Organic farming sustains the health of soils, ecosystems and people. Principles of organic farming are crop rotation, green manure, composting, mechanical cultivation and biological control. Pest is anything which causes damage to the crops. Pest management in organic farming to minimize the crop losses, to minimize the environmental pollution, to approach towards sustainability, maintain quality as well as quantity of produce, nullify the negative effects of green revolution, ensuring food security, decreases bio-hazards created in the food chain due to presence of chemicals, controlling the pests getting resistant to chemicals. In organic farming allow the use of chemicals nothing but naturally occurring substances such as pyrethrin and rotenone. Avoid the use of broad spectrum synthetic pesticides, which promote the occurrence of secondary pest such as spiders, mites and BPH. Organic approach for pest management enhance habitat for beneficial insects to increase population, reduce stress on crop, use adapted varieties and use of non-chemical methods to control pests (Bt, hand picking, row covers, alternating planting dates, traps).

KEYWORDS: Organic Farming, Pest Management, Sustainability, Ecosystem.

INFLUENCE OF MICRONUTRIENTS ON GROWTH AND YIELD OF EARLY CAULIFLOWER**MAHESH KUMAR***Nalanda College of Horticulture, Noorsarai, Bihar Agricultural University, Sabour*

Cauliflower (*Brassica oleracea* var. *botrytis* L.) is a heavy feeder of macro and micronutrients but most of the micronutrients found scarce in the crops which leads to low yield and poor quality of cauliflower. Injudicious use of chemical fertilizers is one of the major reasons for inferior quality and low productivity of cauliflower. Imbalanced fertilizer use has led to multi-nutrient deficiencies particularly of boron, and zinc resulting in poor yield. Therefore, for getting higher and economical yield, applications of boron along with zinc are essential. Keeping in view of the above fact, a field experiment was conducted during Rabi season 2016-17 in the experimental farm area of the Nalanda College of Horticulture, Noorsarai (BAU, Sabour) in R.B.D. factorial design with three replications comprising of 15 treatment combinations. The variety used in the experiment was- Sabour Agrium. From the results of the experiment it was found that **significantly higher plant height (cm), Curd diameter (cm), curd depth (cm), net curd weight (kg) and yield (152.22 q/ha)** were obtained with the application of boron @ 2.0 kg/ha + zinc 5.0 kg/ha which was at par the application of boron @ 3.0 kg/ha + zinc 7.5 kg/ha in respect of calculated yield (144.44 q/ha) of cauliflower.

EFFECT OF AMLA (*EMBLICA OFFICINALIS*) ON THE GROWTH PARAMETERS OF GRASS CARP FINGERLINGS IN TARAI CONDITIONS OF UTTARAKHAND**MAHIMA TAMTA* AND AMITA SAXENA***Department of Fisheries Resource Management, College of Fisheries, G.B.P.U.A.&T., Pantnagar*

Embllica officinalis, is also known as amla, has been used in Ayurveda, the ancient system of Indian medicine. Amla has been used for

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

curing many disorders such as common cold, scurvy, cancer and heart diseases in humans. It is supposed that the major factor responsible for all these curing activities is Vitamin C (Ascorbic acid), which is contained in large proportion in the pulp of amla. The present study was conducted to study the effect of different concentrations of amla as a feed additive on the growth parameters of Grass Carp fingerlings. Four experimental diets, T0, T1, T2 and T3, were prepared with dried amla powder as a feed additive mixed @ 0% (Control), 1%, 5% and 10% of feed, respectively. The results showed that the all the growth parameters were better in all the fishes fed with T3 (10% dried amla per kg feed).

Keywords: vitamin C, *Emblca officinalis*, carps, , growth parameters.

GENETIC VARIABILITY, HERITABILITY AND GENETIC ADVANCE IN DURUM WHEAT (*TRITICUM DURUM*)

MALBHAGE A. B.*; SHEKHAWAT V. S.; MEMON J. T.

Junagadh Agricultural University, Junagadh-362001

The experiment was carried out to assess genetic variability with respect to grain yield and its attributes with a set of 40 genotypes of durum wheat (*Triticum durum*) at Wheat Research Station, Junagadh Agricultural University, Junagadh during Rabi 2016-17 in randomized block design with three replications. The characters studied were days to 50% flowering, days to maturity, grain filling period, plant height, number of productive tillers per plant, ear length, number of grains per main spike, grain weight per main spike, grain yield per plant, biological yield per plant, harvest index and 100-grain weight.

The analysis of variance revealed highly significant differences among the mean square due to genotypes for all the characters studied. Grain weight per main spike recorded maximum phenotypic range of variation followed by grain yield per plant and number of grains per main spike. The values of phenotypic coefficient of variation were slightly higher than that of genotypic coefficient of variation for all the traits studied, indicating less effect of environment on the expression of characters studied. High genotypic and phenotypic coefficient of variation were observed for grain yield per plant followed by grain weight per main spike, number of grains per main spike, 100-grain weight, number of productive tillers per plant and biological yield per plant. High heritability coupled with high to moderate genetic advance expressed as per cent of mean were observed for days to 50% flowering, number of productive tillers per plant, plant height, ear length, grain yield per plant, biological yield per plant and 100-grain weight, which may be attributed to the preponderance of additive gene action and possessed high selective value and thus, more emphasis should be given to these characters for genetic improvement of grain yield.

Key words: Variability, heritability, genetic advance, *Triticum durum*.

MOLECULAR BASIS OF HOST PATHOGEN INTERACTION

MALEMPATI SUBHASH SRISANJAY¹

Department of Plant Pathology, JNKVV, College of Agriculture, Jabalpur, MP

Plant pathogens have evolved numerous strategies to obtain nutritive materials from their host and plants in turn have evolved the preformed physical and chemical barriers as well as sophisticated to combat pathogen attacks. Understanding how plant and pathogen interact with each other is crucial for developing a sustainable agriculture. During the long history of co-evolution between host and pathogens, plant immune response has culminated in a highly defense system that is able to resist potential attack by microbial pathogens. As plants lack mobile defender cells and somatic adaptive systems; they must be relying on the innate immunity of each cell and on systemic signal emanating from infection sites. The perception of the pathogen is achieved through receptors, a surveillance system capable of recognizing both conserved molecular patterns and specific effector proteins and activation of the corresponding defenses. Rhizosphere colonization by certain bioagent like PGPF PGPR strains results in a state of heightened resistance in plants, locally and systemically, to subsequent pathogen attack. During the colonization process, a complex molecular dialogue is established between plants and the microorganisms in which signaling molecules (elicitors) play an essential role. Various molecules associated with the basic metabolism of microbes, such as cell wall glucans, chitin oligomers and glycopeptides have been described elicitor activity. One important outcome of some plant microbe interactions is the induction of plant defenses mediated by the activation of Induced Systemic Resistance (ISR) systemic acquired resistance (SAR) and Pathogen related proteins (PR) involved genes. An integrated approach based on the combined knowledge of the molecular basis of 'defense systems' used by the plant and the 'assault systems' used by pathogens will help us to design novel methods for plant disease management.

HIGH INTENSITY SOIL SAMPLING: A BOON TO SITE SPECIFIC NUTRIENT MANAGEMENT**MAMTA PHOGAT^{*1}, RITADAHYA², SUNIL KUMAR³ AND BHAWNA BABAL⁴**^{1,2,4}*Department of Soil Science, CCS Haryana Agricultural University Hisa-125004, ³Department of Soil Science and Agricultural University, SKRAU, Bikaner, Rajasthan-334006*

Presently the world is facing population explosion and it is one of the greatest challenges to ensure food security to the growing global population which is projected to rise to around 10 billion by 2050 to meet their nutritional needs. There is urgent need to increase farm productivity and total food production on sustainable basis without compromising on natural resources and environment. Now-a-days, due to intensive cropping, imbalanced use of fertilizers and cultivation of high yielding crop varieties leads to deterioration of soil health and increased air, soil and water pollution. The negative nutrient balance due to the imbalanced use of fertilization to the tune of ~810 Mt has been resulted in nutrient mining and hence decreased productivity of soil. As a way out to this dilemma, site-specific nutrient management is one of the best agriculture practices which is climate-compatible and it will help to meet the Zero Hunger Challenge. Variability of plant-available nutrients Within field often results in different fertilizer requirements across a field. Site-specific nutrient management takes into account various activities viz; measuring spatial variability, analyzing the data obtained from these measurements, using information gained from this analysis to effect changes in management practices, and determining whether the resulting benefits are cost effective. GIS (Geographical Information System), and GPS (Global Positioning System) are the best techniques for site-specific nutrient management for precision agriculture. GPS tools receive signals from a network of orbiting satellites and calculate them to give exact position of a point. GIS computes this background data of given locations to generate a complex view about the whole field. It provides opportunity to assess variability in the distribution of native nutrients and other yield limiting/improving soil parameters over a large area and to make valid decisions for site-specific nutrient management. This will result in low input yield optimization along with maintenance of soil health, soil quality and sustainable environment.

Key Words: Food security, Nutrient Mining, Spatial Variability, GIS, GPS, Soil health and quality

USE OF MODIFIED CLAY AND PILLARED CLAY FOR REMEDIATION OF HEAVY METALS**MAMTA, RAJENDRA BAIRWA, SUMAN LATA, DIPTI KUMARI***Department of Soil Science and Agricultural Chemistry, Bihar Agricultural University, Sabour, Bhagalpur- 813210*

Heavy metals contamination of the environment has become a serious problem due to their non-degradability and biomagnifications (Mapanda *et al.*, 2005; Kurniawan *et al.*, 2006; Singh *et al.*, 2010). Common methods that are available for the removal of heavy metals contamination include chemical precipitation, reverse osmosis, ion exchange, membrane separation, chemical oxidation and electro dialysis. Adsorption is the most preferred method for removal of heavy metals due to its simplicity and its high effectiveness (Gupta *et al.*, 1998; Gupta and Ali 2004; Shafaei *et al.* 2007; Sdiri *et al.* 2011). The High metal adsorption capacity of clay minerals (because of their large specific surface area and reactive functional groups) makes one of the most common amendments for metal adsorption/stabilisation. There are various modifications like acid activation, thermal treatment, clay-rubber complex, treatment with cationic surfactant and pillaring by different type of poly (hydroxo metal) cations etc. that increase the metal loading capacity of clay minerals. Pillared clays have emerged as potential adsorbents for the removal of heavy metal ions due to their large surface area and the abundance and low cost of clays that it used as raw material, as well as to the fact of being tunable in terms of properties. PILCs exhibit multi-charged centers, large area, high interlayer space and thermal stability. Characterization of these properties was carried out by using of different technique like XRD, FTIR, SEM, DTA/TGA and zetametry. Amending the soil with Al-bentonite at 2.5% resulted in 16, 36 and 16% reduction in EDTA extractable Zn, Cu and Ni respectively and also reduced the content of Zn, Cu and Ni in amaranth shoot by 24%, 31% and 53% respectively (Kumararaja *et al.*, 2017).

Key words - Heavy metals, Adsorption, Pillared clay.

ASSESSMENT OF AVAILABLE MICRONUTRIENTS AS AFFECTED BY AGRICULTURAL LAND-USES IN SOUTH WESTERN PLAINS OF PUNJAB, INDIA**MANDALAGNIVA^{1*} AND DHALIWALS²***Department of Agricultural Chemistry and Soil Science, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, Nadia, West Bengal 741252, INDIA, Department of Soil Science, Punjab Agricultural University, Ludhiana 141004, Punjab, INDIA*

To study the impact of agricultural land-uses on distribution of available micronutrients in soil, samples were collected from semi-arid sub-tropical region of Punjab, in and around Dhanaula (30°18' N, 75°27' E); district Barnala, Bhucho (30°15' N, 75°03' E) and Phul (30°19' N, 75°14' E); district Bathinda, under three land-uses viz. cropland, horticultural and uncultivated land and were analyzed. The results indicated that soils were slightly saline in nature and sandy loam to loamy sand in texture. The DTPA extractable contents varied

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

from 0.19-4.07 mg kg⁻¹ for zinc (Zn), 0.16-1.24 mg kg⁻¹ for copper (Cu) 1.45-15.43 mg kg⁻¹ for iron (Fe) and 1.09-4.16 mg kg⁻¹ for manganese (Mn) irrespective of land-uses and soil depths. The values of available micronutrient contents were recorded highest under horticultural land followed by cropland and uncultivated land. Gradual decrease along the depth was observed almost under all three land-uses. Uncultivated lands were expected to be deficient in micronutrients due to prolonged erosional loss and lack of input. But croplands were also found deficient in available Zn, Cu and Mn. Widespread Zn deficiency under cultivation which might be attributed to crop removal and low carbon content as highest variability of Zn was found ($R^2 = 0.822$, $P = 0.001$) with respect to soil organic carbon (SOC). Cropland exhibited medium to sufficient range in terms of available Fe. Overall sufficiency was noticed under horticultural land regarding the availability of all four studied micronutrients which might be due to comparatively finer soil texture and greater addition of organic matter in the form of leaf litter fall and root deposition. Significant positive relations of micronutrients with SOC and finer particles (silt, clay and silt plus clay) might be the plausible reason behind it. Hence, assessment micronutrient availability under different land-uses is imperative to evaluate the potential of soils as well as for better selection of land-uses for achieving sustainability.

Key Words: Land-use, DTPA extractable available micronutrients (Zn, Cu, Fe and Mn), Soil fertility, Soil sustainability.

DOUBLING OF FARMERS INCOME TILL 2022

MANGI LAL GODARA*, ANIL KUMAR CHOUDHARY, SUNIL KUMAR MEENA*****

Department of Extension Education, College of Agriculture, JNKVV, Jabalpur(M.P.) India -482004, Department of Extension Education, College of Agriculture, SKRAU, Bikaner (Raj.) India -334006, Department of Extension Education, PDKV Akola Maharashtra, India-444104

Income is the most relevant measure to assess farmers' economic well being and sectoral transformation. The crises and distresses plaguing the sector endanger the very livelihoods and welfare of the farmers. Indian Government with the intention giving enough policy thrust on income security, proposed to double the farmers' income by 2022, platinum jubilee year of the Indian independence. The present study analysed the current status of farmers' income across holding size and regions and attempted to decipher the scope and pathways for doubling income through potential drivers. The spatial and temporal trends in farm household income from crop production, livestock farming, wages and non-farm activities have been analysed for better understanding of the present scenario. The study tracked the farmers' household income across regions and holding size between 2003 and 2013 using the countrywide situation assessment survey data collected by the National Sample Survey Office (NSSO) and deciphered the scope and potential for doubling the farmers' income (DFI) by 2022. The findings from the NSSO data indicated that the share of income has increased drastically from 5 per cent to 12 per cent in the case of livestock farming, 45 per cent to 48 per cent in crop production, while that of the wages and non-farm have declined between 2003 and 2013. The challenges faced by the farming community in the coming years have been highlighted for devising relevant pathway and strategies to enhance the income.

Key word:- farmers' income, production, farming etc.

SUSTAINABILITY IN AGRICULTURE: A REVIEW OF POLICIES

MANGI LAL JAT, AJAY PRATAP SINGH KIRAR

M.Sc Scholar, Department of Extension Education, JNKVV-Jabalpur (M.P.) India -482004

The new policy seeks to introduce economically viable, technically sound, environmentally non-degrading and non-hazardous and socially acceptable use of natural resources of the country for promoting the concept of sustainable agriculture. In order to fulfill this strategy, the following measures are suggested in the new policy: To use unutilized barren wastelands for agriculture and afforestation. To contain biotic pressures on land and to control indiscriminate division of agricultural lands for non-agricultural uses. To enhance cropping intensity through multi-cropping and inter-cropping. To emphasize rational use of ground and surface water so that over-exploitation of ground water resources can be checked. To adopt better technologies such as drip and sprinkler irrigation system so as to arrange more economic and efficient use of water. To adopt vigorously a long-term perspective plan for sustainable rain-fed agriculture by adopting watershed approach and water harvesting method for development of two-thirds of cropped area of the country which is dependent on rainfall. Involvement of farmers and landless labourers will be sought in the development of pastures/ forestry programmes on huge public wasteland by providing adequate financial incentives and entitlement of trees and pastures.

Key Word:- sustainable agriculture, afforestation, etc.

IMPACT OF VARIOUS TYPES OF FERTILIZERS ON MORPHO-PHYSIOLOGICAL AND BIOCHEMICAL PARAMETERS OF OKRA**MANIKABALI*, TINU ANAND KAIN, SHAHID UMAR***Department of Botany, School of Chemical and Life Sciences, Jamia Hamdard, New Delhi-110062*

Okra, a member of the Malvaceae family, is one of the oldest cultivated crops in the world, dominantly found in tropical, sub-tropical and warm temperate regions of the world. Its native origin is Ethiopia and Sudan and is widely consumed in India. It is well-known fact that dosage and composition of fertilizers affect the crop growth and yield. To investigate the influence of inorganic, organic fertilizers and bio-fertilizers on morpho-physiological characters of okra, field experiments were conducted at the Jamia Hamdard, Delhi during Kharif season (July-Sept) in the year 2018. The experiment was carried out in a randomized complete block design with nine treatments each with three replicates utilizing fertilizers available in the market such as dung compost, *Azospirillum*, P.S.B., VAM, Biochar, *Azotobacter*, *Azospirillum*. The experimental results showed considerable variations among the treatments in respect of morphological characters such as plant height, number of leaf per plant, number of pods per plant, and physiological characters like fresh weight and dry weight. The plants were also tested for biochemical parameters like chlorophyll content, protein content, phenol content, sugar content. The result of biochemical parameters also showed a significant difference, varying in different treatments. We found that maximum yield could be achieved by rational application of combinations of fertilizers.

KEYWORDS: Okra, fertilizers, VAM, bio-fertilizers.**HIGH-THROUGHPUT PHENOTYPING: A NEW FRONTIER APPROACHES FOR CROP BREEDING AND CROP ARCHITECTURE****MANISH KUMAR CHOUDHARY*, GAYATRI KUMAWAT, MUNNESH KUMAR, ASHOK SINGAMSETTI,***Department of Genetics and Plant Breeding, Institute Of Agricultural Sciences, Banaras Hindu University, Varanasi-221005, U.P. India*

Constraints in field phenotyping capability limit our ability to dissect the genetics of quantitative traits, particularly those related to yield and stress tolerance (e.g., yield potential as well as increased drought, heat tolerance, and nutrient efficiency, etc.). precise phenotyping is the new frontiers approaches. The development of effective field-based high-throughput phenotyping platforms (HTPPs) remains a bottleneck for future breeding advances. However, progress in sensors, aeronautics, and high-performance computing are paving the way. Here, we review recent advances in field HTPPs, which should combine at an affordable cost, high capacity for data recording, scoring and processing, and non-invasive remote sensing methods, together with automated environmental data collection. Laboratory analyses of key plant parts may complement direct phenotyping under field conditions. Improvements in user-friendly data management together with a more powerful interpretation of results should increase the use of field HTPPs, therefore increasing the efficiency of crop genetic improvement to meet the needs of future generations.

PRECISION FARMING IN VEGETABLE PRODUCTION**MANISH KUMAR, ADITYARANJAN AND DEEPAK MAURYA***Department of Horticulture (Vegetable and Floriculture), Bihar Agricultural University, Sabour, Bhagalpur, Bihar*

Precision farming is a new concept and very popular as well as fastest growing technology in vegetable production. It is a technique of cultivation which minimizes waste of inputs and resources to maximum higher production and productivity. The system takes into account efficient management of resource through location specific intervention. It promotes in deploying variable management practice within a field according to site conditions. Global positioning system (GPS technology implies accuracy when dynamic in the field, providing navigation and positioning capability anywhere on earth, anytime under any all conditions), Geographic information system (GIS), remote sensing, yield monitoring device, soil, plant and pest sensors, variable rate technologies for application of inputs are enabling in precision production system. Micro-propagation, micro-irrigation, fertigation, mulching, protected cultivation, organic farming, integrated nutrient, water, pest and disease management, use of modified crop varieties, hi-tech post harvest handling etc. form the part of vegetable production in precision farming. If these technologies sensibly implemented, farmers could be benefited in different ways. In the short term, growers can use remote sensing which forecast and give estimation of intensify problems such as water stress, nutrient deficiency and pests/diseases more efficiently. Database building **benefits will be in the form of accurate farm document keeping** for effective management of inputs, property, machinery and labor, and efficient monitoring of environmental quality through recording the amounts and location of input during applying at exact locations that produce maximum profit margins. Precision farming techniques also **increase opportunities for skilled employment** in farming, and provide new tools for evaluating multifunctional character (including non - market functions) or agriculture and land.

NOURISH THE SOIL NOT TO PLANT: A KEY OF SUSTAINABILITY**MANISH YADAV, GOPAL LAL DHAKAR AND JITENDRA CHOUDHARY***(Department of Soil Science And Agricultural Chemistry) SKN Agriculture University, Jobner, Jaipur Rajasthan 303328*

Today's Indian agriculture becomes a chemical oriented and soil health declines day by day with this view need of sustainable agriculture becomes essential. Harmful effects of chemical fertilizers on soil health, environmental quality, biodiversity and self-reliance of farming system are serious concerns. Soil health is continuously decreasing due to use of synthetic chemical fertilizers, to overcome this problem we should go for organic farming. Addition of farm yard manure is very helpful. Agricultural chemicals are replaced by use of organic manures is better way for maintaining soil health by improving soil structure, water holding capacity and nutrient binding to the soil. To sustain Indian agriculture integrated farming system should be followed in long term and waste lands should be brought under cultivation according to their land capability. Continuous degradation of soil suggest us that "Feed to the soil not to Plant". A balance nutrition to the soil is very essential for maintaining the Soil health and quality.

Key words: Soil health, Organic farming, Soil fertility, Sustainable agriculture.

STUDIES ON EFFICACY OF PRE-MIX PENOXSULAM + PENDIMETHALIN ON ECONOMICS OF DIRECT SEEDED RICE**MANISHA URAON¹, G.K. SHRIVASTAVA² AND MADAN JHA***Dept. of Agronomy, IGKV, Raipur (C.G.), Dept. of Agronomy, IGKV, Raipur (C.G.), Dept. of vegetable science, BTC CARS, Bilaspur (C.G.)*

The present investigation entitled "Studies on efficacy of pre-mix penoxsulam + pendimethalin on weed growth, yield and economics of direct seeded rice" was carried out at Research cum Instructional Farm, Indira Gandhi Krishi Vishwavidyalaya, Raipur during *kharif* season of 2015. The soil of experimental field was sandy loam in texture (*Inceptisols*), neutral in pH and has 0.44 % organic carbon, low nitrogen, medium phosphorus and high potassium content. Experiment was laid out in Randomized Block Design (RBD) with three replications. The treatments consisted of fourteen different weed management treatments viz, T₁ Penoxsulam + Pendimethalin (10+240 g/l) SE @ 20 + 480 g a.i. ha⁻¹, T₂ Penoxsulam + Pendimethalin (10+240 g/l) SE @ 22.5 + 540 g a.i. ha⁻¹, T₃ Penoxsulam + Pendimethalin (10+240 g/l) SE @ 25 + 600 g a.i. ha⁻¹, T₄ Penoxsulam + Treatment Penoxsulam + Pendimethalin (10+240 g/l) SE @ 50 + 1200 g a.i. ha⁻¹ (T₅) fetched the maximum net return (Rs 46914.13 ha⁻¹) followed by Penoxsulam + Pendimethalin (10+240 g/l) SE @ 100 + 2400 g a.i. ha⁻¹ (T₆) (Rs 45753.13 ha⁻¹) and Penoxsulam 24% SC @ 25 g a.i. ha⁻¹ (T₇) (Rs 43905.13 ha⁻¹). While, the highest B:C ratio (2.05) was noted under the application of Penoxsulam 24% SC @ 25 g a.i. ha⁻¹ (T₇) followed by Penoxsulam + Pendimethalin (10+240 g/l) SE @ 50 + 1200 g a.i. ha⁻¹ (T₅) (2.00) and Hand weeding at 20 & 35 DAS (T₈) (1.57). (10+240 g/l) SE @ 50 + 1200 g a.i. ha⁻¹, T₉ Penoxsulam + Pendimethalin (10+240 g/l) SE @ 100 + 2400 g a.i. ha⁻¹, T₁₀ Penoxsulam 24% SC 20 g a.i. ha⁻¹, T₁₁ Penoxsulam 24% SC @ 22.5 g a.i. ha⁻¹, T₁₂ Penoxsulam 24% SC @ 25 g a.i. ha⁻¹, T₁₃ Pendimethalin 30% EC @ 540 g a.i. ha⁻¹, T₁₄ Pendimethalin 30% EC @ 600 g a.i. ha⁻¹, T₁₅ Pendimethalin 30% EC @ 1000 g a.i. ha⁻¹, T₁₆ Pendimethalin 30% EC @ 1500 g a.i. ha⁻¹, T₁₇ hand weeding at 20 and 35 DAS and T₁₈ untreated check. Rice The rice variety MTU-1010 was tested under different combinations of herbicide and maintaining the recommended nutrient (N:P:K) doses of 100:50:30 kg ha⁻¹. Rice seed was direct seeded on June 27th, 2015 with a spacing of 20 x 10 cm and harvesting was done on October 29th, 2015. Treatment Penoxsulam + Pendimethalin (10+240 g/l) SE @ 50 + 1200 g a.i. ha⁻¹ (T₅) fetched the maximum net return (Rs 46914.13 ha⁻¹) followed by Penoxsulam + Pendimethalin (10+240 g/l) SE @ 100 + 2400 g a.i. ha⁻¹ (T₆) (Rs 45753.13 ha⁻¹) and Penoxsulam 24% SC @ 25 g a.i. ha⁻¹ (T₇) (Rs 43905.13 ha⁻¹). While, the highest B:C ratio (2.05) was noted under the application of Penoxsulam 24% SC @ 25 g a.i. ha⁻¹ (T₇) followed by Penoxsulam + Pendimethalin (10+240 g/l) SE @ 50 + 1200 g a.i. ha⁻¹ (T₅) (2.00) and Hand weeding at 20 & 35 DAS (T₈) (1.57).

EFFECT OF DIFFERENT SHADE NET STRUCTURES ON REFERENCE CROP EVAPOTRANSPIRATION**MANISHA JAGADALE¹, MAHESH JADHAV¹, NANDINI THAKUR², SHAILENDRA GADGE³***ICAR-Central Institute of Agricultural Engineering, Bhopal, 462038., ²SRF, ICAR-Central Institute of Agricultural Engineering, Bhopal, 462038. Department of IDE, ASCAE, MPKV, Rahuri.*

Shade net structures provide favorable environment for the crop growth there by for achieving greater yield and high quality produce. Accurate irrigation scheduling in protected cultivation structures is one of the important factors in achieving higher yields and avoiding loss of quality. Stevenson's screens were installed to monitor the different climatological parameters *i.e.* maximum and minimum temperature, relative humidity, vapor pressure in shade net houses as well as open field. An investigation was carried out to evaluate the effect of red and green (35, 50 and 75% shade) shade net houses as well as open field cultivation condition (control) on reference crop

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

evapotranspiration (ET_r) during kharif, rabi and summer season using *Hargreaves-Samani* method. Study showed that the ET_r at different structures was reduced by about 11.47, 15.84, 22.61 and 24.31% in red and green with 35, 50 and 75% shades, respectively in comparison to control. The ET_r values during the study period were varied from 5.41 to 7.3 mm for red, 4.69 to 7.30 mm for green (35%), 4.20 to 6.85 mm for green (50%) shade and 4.11 to 7.05 mm for green (75%) shade net house, while the same was 6.03 to 7.67mm for the control plot.

DISPERSAL AND ETHNOBOTANY OF WEEDS IN HARYANA**MANISHA¹ AND RAJBIR SINGH KHEDWAL²**

¹CCS Haryana Agricultural University, Hisar-125004, Haryana, India, ²Department of Agronomy, Punjab Agricultural University, Ludhiana-141004, Punjab, India

Ethnobotany is studying the beneficial aspects of weeds or wild plants towards utilization in a number of ways for humans and society as whole. Haryana which is situated in north India, have immense richness in biodiversity and ethnobotanical uses of noxious, objectionable and other weed flora. Rice, cotton, bajra, cluster bean, wheat and mustard are main crops in Haryana. Dominant weed flora of kharif crops are *Echinochloa* spp., *Digitaria sanguinalis*, *Commelina benghalensis*, *Dactyloctenium aegyptium*, *Celosia argentea*, *Cyperus rotundus* and *C. iria* etc. Dominated weed flora in rabi crops are *Phalaris minor*, *Chenopodium* spp., *Euphorbia hirta*, *Rumex dentatus*, *Coronopus didymus*, *Orobancha aegyptiaca* etc. *Argemone mexicana*, *Parthenium hysterophorus*, *Calotropis procera* are mainly found in uncultivated land and on roadside.

Traditional uses of these weeds cure many diseases and give vital importance in routine life. *Amaranthus viridis* is a good source of iron and used as vegetable. *Anagallis arvensis* treat leprosy and; hydrophobia and use as cattle feed to expel out leeches. Flower and latex decoction of *Argemone mexicana* can treat jaundice and skin problems. *Calotropis procera* cure leucoderma. Roots of *Chenopodium album* are used for liver infection and jaundice. Weeds like *Rumex dentatus* and *P. minor* used as a fodder for cattle. Mixture of fruits and roots of *Tribulus terrestris* with boiled rice is remedy for urinary troubles. Roots decoction of *T. portulacastrum* treat asthma and may be practiced as an antidote to alcohol poisoning. *P. hysterophorus* cure dysentery and skin disorders. Dry tuberous roots of *C. rotundus* are aromatic and; used in perfumes and incense. *Cynodon dactylon* is a good soil binder. Plant extract of *Coronopus didymus* is used for bone disorders. *Cirsium arvense* is a noxious weed of wheat and cure worms in children. It may be concluded from the above mentioned study that Haryana have valuable wealth of flowering plant as well as a rich traditional and folk knowledge of ethnobotanical uses of weeds. Marginal farmers may draw away an additional source of income from this folk knowledge.

Key words: Ethnobotany, Haryana, medicinal use, weed dispersal

VEGETABLE CROPS FOR FOOD AND NUTRITIONAL SECURITY**MANJEET KUMAR,¹ C.N. RAMSHARVAN KUMAR,¹ AND KRISHAN KUMAR²**

Department of Vegetable Science¹, Department of Plant Pathology², N. D. U. A. & T. Kumarganj Faizabad - 224229 (U.P.)

Last decade of the twenty century was a witness to series of enormous reformation and changes in all aspects of life including social and economic upheavals necessarily. Have ramification for present and future generations. Food and nutritional status is a measure of health condition of an individual as affected primarily by intake of food and nutrition security. Health is not only the absence of disease but is state of complete mental and physical well-being in relation to the productivity and performance of an individual. Good nutritional status can only realized and sustained when individuals with in families and communities are food secure. Food security has been defined as access by all people at all times to the food needed for a healthy life. Nutrition plays a critical role in human resource development since deficiencies, in essential nutrients lead to malnutrition, which affects an individual mental and physical state, ensuring in poor health and poor work performance. In addition, a hungry, malnourished child may have mild to serious learning disabilities, resulting in poor school performance; a sick, poor nourished individual will not respond well. Losses and waste occur throughout the food system from primary production of agricultural commodities and fish catch to food intake. These losses and waste may be caused by the practice and behavior of farmers, consumers, trader, processors and others in the food systems or by existing socio-economic losses to societies and individual agents in the food system. Quality food is incomplete in the absence of vegetable from the diet and availability of good quality food is also depends on the proper functioning of ideal agro techniques, proper management of the agro produce and marketing channels which highly responsible for sufficiency in food security. Vegetable including tuber crops plays pivotal role in fulfilling the one of the said objective of national food security mission because they are the better source of minerals, vitamins and carbohydrate as a source of energy.

EVALUATION OF SELECTED BOTANICALS FOR THEIR EFFICACY AGAINST MAYDIS LEAF BLIGHT OF MAIZE UNDER FIELD CONDITIONS**MANJEET SINGH AND RAKESH MEHRA***Department of Plant Pathology, CCS Haryana Agricultural University, Hisar-125004*

Maize (*Zea mays* L.) is the third most important food grain in India next to wheat and rice and is popularly known as queen of cereals. About 65 pathogens infect maize and out of these, maydis leaf blight (MLB) caused by *Bipolaris maydis* (Nisikado and Miyake) Shoemaker is considered as one of the most serious diseases. The disease is widely distributed in India during *kharif* season. Maydis leaf blight appears every year with incidence ranging from 20-85 per cent in Haryana. The disease has the potential to reduce the grain yield up to 41 per cent in susceptible cultivars. Keeping in view of environmental pollution and ecological imbalance caused by the use of chemical fungicides, an effort has been made in the present experiment to control the maydis leaf blight by using **botanicals**. Twelve **botanicals** (Garlic clove, neem leaves, onion bulb, eucalyptus leaves, aonla leaves, aak leaves, tulsi leaves, turmeric rhizomes, congress grass, Acacia leaves, jamun leaves and datura leaves) were **evaluated** at 20 per cent concentration against maydis leaf blight under field conditions during *kharif* 2015. All the **botanicals** were sprayed at initiation of the disease followed by second spray at 15 days interval. In the present study, all the botanicals showed significant reduction in per cent disease intensity of maydis leaf blight in comparison to control. Among the various **botanical extracts** tested, Garlic clove was found to be most effective as it showed minimum per cent disease intensity, maximum disease control and maximum grain yield followed by neem leaves. The other **botanicals** in descending order of efficacy were turmeric rhizomes, tulsi, onion, aak, datura, eucalyptus, aonla, congress grass, jamun, *whereas* acacia was least effective **and** which gave maximum per cent disease intensity, minimum disease control and minimum grain yield as compared to control. These findings will be helpful in developing integrated disease management strategies for the control of maydis leaf blight of maize.

INNOVATIVE APPROACHES AND CHALLENGES FOR DOUBLING FARMERS INCOME BY 2022**MANJU LOURA* AND POOJA PANWAR** AND SUMAN GHALAWAT******Deptt. of Business Management, CCS Haryana Agricultural University, Hisar, Haryana., Deptt. of Business Management, CCS Haryana Agricultural University, Hisar, Haryana., Deptt. of Business Management, CCS Haryana Agricultural University, Hisar, Haryana*

Agriculture, with its related sectors, is indisputably the largest livelihood provider in India, more so in the massive rural areas. All the nations facing problems of poverty, hunger and malnutrition will need to accelerate their agricultural growth for achieving sustainable development goals. The present paper focusses on need, challenges, and innovative approaches for doubling farmers' income. To ensure that the mission of doubling farmers' income moves in the right direction and is accomplished within the stipulated period, it is important that accurate information on key indicators of agricultural performance is generated and made available to policymakers and other stakeholders for their effective monitoring and corrective action. The major challenges for doubling farmers' income are climate change, Cost saving, post-harvest losses and less developed infrastructure. The Government of India has taken appropriate measures to increase farm income, stabilize production and, consequently, improve small farm productivity. Innovative approaches include: Quality seeds and optimum use of fertiliser are important pillars of growth in productivity, need of increasing power supply to agriculture sector. Attention should be paid to good policy framework for farmers to provide them better support. The target of doubling farmers' income by 2022, though apparently not easy yet a very laudable goal, augurs well of Government's intention to help farmers. It is also clear that if concerted efforts, as per suggested action plan, are made in a Mission Mode, chances of making agriculture an engine of national economic growth and for smallholder farmers a respectable profession are indeed much brighter. . It is also a fact that India will remain predominantly an agricultural country during most of the 21st century.

Keywords: sustainable development, innovative approaches, post-harvest losses and predominantly**CHALLENGES AND FUTURE PERSPECTIVES OF PLANT BIOTECHNOLOGY****MANJU* ANITA** OMPRAKASH*****Department of Biotechnology* Department of Horticulture**, College of Agriculture-Bikaner, SKRAU-334006*

Advances in understanding plant biology, novel genetic resources, genome modification, and omics technologies generate new solutions for food security and novel biomaterials production under changing environmental conditions. New gene and germplasm candidates that are anticipated to lead to improved crop yields and other plant traits under stress have to pass long development phases based on trial and error using large-scale field evaluation. Therefore quantitative, objective, and automated screening methods combined with decision-making algorithms are likely to have many advantages, enabling rapid screening of the most promising crop lines at an early stage followed by final mandatory field experiments. The combination of novel molecular tools, screening technologies, and economic evaluation should become the main goal of the plant biotechnological revolution in agriculture.

Keywords- Crop biotechnology, Abiotic and Biotic stress tolerance, Transgenic plants, Food security, Bio-materials, Molecular breeding etc.

IMPACT OF POLLUTED HINDON RIVER WATER IRRIGATION ON SOIL HEALTH AND ASSESSING RISK IN RELATION TO TRANSFER OF METALS TO HUMAN FOOD CHAIN

MANJUNATH DALI¹, RAJENDRA SINGH^{2*}, DEBASIS GOLUI², MAN SINGH¹ AND DHARASINGH GURJAR¹

¹Water Technology Center, ICAR-Indian Agricultural Research Institute (ICAR-IARI), New Delhi - 110 012, India, ²Division of Soil Science and Agricultural Chemistry, ICAR-Indian Agricultural Research Institute (ICAR-IARI), New Delhi - 110 012, India

The present study was carried out with the objective of assessing the impact of polluted river water irrigation on soil health and assessing risk in relation to transfer of metals to human food chain. In all, 45 paired soil and plant samples (Mustard, Rice, Pumpkin, Cucumber, Spinach, Turmeric, Brinjal, Marigold, Pearl millet, Mung bean, Carrot and Pigeon pea) were collected from river irrigated soils covering Makreda, Rewari, Nithari, Kinauni, Barnawa, Parsi villages of Western U.P. As per the geo-accumulation indices (I_{geo}), PI, IPI and PLI, all the river water irrigated soils were loaded with high level of metals (Zn, Cu, Ni, Pb and Cd) and required immediate intervention to ameliorate metal contamination. Among the river water irrigated soils, least value of soil quality index (SQI) was recorded in Nithari and Barnawa (PCA-SQI = 0.28). Based on PCA-SQI, the extent of soil health deterioration due to metal contamination follows the order: Nithari (0.28) = Barnawa (0.28) > Makreda (0.30) > Rewari (0.38) > Parsi (0.39) > Kinauni (0.44). All the plants grown on river water irrigated soils accumulated much higher amount of Zn, Cu, Ni, Pb and Cd compared to plants grown on tubewell-irrigated soils. Taking all the crops together, relative orders of transfer of metals from soil to plants grown on river water irrigated soils were Zn > Cu > Ni > Cd > Pb. The values of hazard quotient (HQ) for intake of trace toxic elements by humans through consumption of rice grain, vegetables (spinach, carrot, cucumber, pumpkin) and mustard grown on river water irrigated soils were well within the safe limit.

“PRECISION FARMING FOR SUSTAINABLE CROPPRODUCTION”

MANJUNATHA.S.K.*

Department of Agronomy, NDRI, Karnal (Haryana), India

Precision farming is site specific farming, smart farming and GPS based farming. Application of principles and technologies to manage spatial and temporal variability associated with all aspects of agricultural production for the purpose of improving crop performance and environmental quality. It includes precision farming gadgets such as chlorophyll meter (SPAD), Green Seeker, laser land leveler etc. With the help of GIS, GPS, RS, yield monitors, variable rate of application of agricultural inputs can be done precisely resulting in the reduction of over dose of inputs, reducing environmental pollution. With the help of site specific nutrient management (SSNM), soil test crop response (STCR), etc. the yield of the crops can be significantly increased in comparison with farmer's conventional practices. Nitrogen fertilizer wastage in cereals can be minimized and yield can be enhanced when N is applied based on the Green Seeker based NDVI values and when it is applied in split doses. With the help of satellite images, one can predict the yield of crops. Leaf area index, biomass and yields, etc. of different crops can be estimated using satellite images. Laser land leveler is one of the successful precision farming instruments in India. Leveled land increases the yield of crops by ensuring equal distribution of all inputs and amount of water requirement also gets reduced significantly resulting in the higher water use efficiency. We can draw the conclusion as, with added advantage of PF it has to be promoted in order to reap its fullest potential. Due to PF technology being sophisticated and high cost, its feasibility under Indian condition seems to be virtual reality but time being, it can be included in agriculture research. Affordable PF gadgets has to be developed for Indian farmers.

Keywords- Precision farming, environment, variable rate, satellite, water use efficiency

EFFECT OF MINERAL MIXTURE TO ENHANCE MILK PRODUCTION AND RETARDED STERILITY

MANOJ KUMAR¹, KIRTIMANI TRIPATHI¹, RAVINDER PAL SINGH² AND PARVINDRA KUMAR³

¹ Krishi Vigyan Kendra, Bulandshahr; ² Krishi Vigyan Kendra, Amroha, ³ Basic Shiksha Vibhag, Shyamli

U. P. is the largest contributor to the national milk production contributing around 18 % of total milk production in the country. It has got the second highest cattle number and highest number of buffalo in the country. Bulandshahr district is known as “Milk Belt” of Uttar Pradesh. The production of district milk has increased to 233.00 lakh ton in 2013 as against 189.00 lakh ton in 2007-2008. A survey was conducted in Bulandshahr district of western U.P. during 2014 - 2016 to find out the constraints faced by dairy farmer in adoption of improved milch animal husbandry practices. Total 120 animal keepers, Blocks namely Bulandshahr, Gulaothi, Lakhaoti and Sikandrabad were selected through random sampling technique. All animals selected were of same age group of 5 to 6 years. 50-60 gram of mineral mixture per day was given to each cow for 120 days. Among different health parameters relating to milk fever problem of animals in village Ginora Sheak, the effect of mineral mixture was of high significance (83% decrease) and milk increased at the lower rate (5%) per animal in village Jainpur. From the study it can be concluded that mineral deficiency is one of the major cause behind the different

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

problems faced by cows with respect to health and physical parameters followed by decreased milk production, fertility and repeated breeding. In the study it was found the all the assessed parameters concluded significant results. Thus mineral mixture was found to be very effective in improving different health aspects of cow.

Key words: Mineral mixture, milch animal, infertility, milk production

INTEGRATED NUTRIENT MANAGEMENT ON FRUIT PRODUCTION

MANOJ KUMAR, YOGESH PRASAD, AJAY YADAV

Department of Horticulture, SVPUA&T, Meerut, UP, India.

Integrated nutrient management helps in the improvement of fruit quality and reduces environmental pollution. It brightens the prospects of export of fruit. INM in fruit crop is not new to our country. For almost the last fifty years fruit cultivation is mainly concentrated on increasing production, productivity and area of fruit crop. Plant nutrient can be supplied from different sources viz. Organic manures, crop residues, Bio-fertilizer and chemical fertilizers. For better utilization of resources and to produce fruit crops with less expenditure integrated nutrient management is best approach. Continuous use of synthetic fertilizer causes ill effect on soil, fruit crop as well as human health the area where chemical fertilizer is used lacking in organic matter, Change in soil structure and chemical fertilizer pollute air and water as well as Chemical fertilizer leave residue in fruits. The major objectives of INM to reduce the cost of production, produce fruit with nutritional quality and to minimize physiological disorder which is suffering from micronutrient deficiencies. Component of INM Organic Manure, Vermicompost, Green manure, Fertilizer, Bio-fertilizer, Nano-fertilizer. Sufficient and balanced application of organic and inorganic fertilizers is a major aspect of INM. INM is the only option for sustainability of soil health improvement in quality of fruits, reduced environmental hazards, increase farm income and also for rural employment generation and ultimately maintains the health of human.

INTEGRATED PEST MANAGEMENT IN HORTICULTURAL CROPS

VINOD KUMAR*, MANOJ KUMAR¹

Department of Entomology, SVPUA&T, Meerut, UP, India. , Department of Horticulture, SVPUA&T, Meerut, UP, India.¹*

Integrated pest management (IPM) is a coordinated system of controlling pests. IPM uses information about the biology of the pest to optimise control measures. IPM focuses on cultural and biological control methods as the first line of defence. This means that the need for chemical pesticides is reduced. Different control and management practices are utilised in IPM with the objective of achieving long term results - Such as (i) Identification of threshold pest level at which action needs to be taken (ii) Monitoring and identification of pests (iii) Prevention the use of management practices to reduce the likelihood of pests (iv) Control once the pest has been correctly identified, monitoring has shown it has reached a threshold level, and preventative measures are no longer appropriate, control measures will be used. Measures with the lowest associated risk are used first. Threshold pest levels are based on a combination of the likelihood of damage; the costs / consequences of damage; and the costs / consequences of control measures. Sometimes a low level infestation by a pest likely to cause minor damage with no significant loss to either crop quality or quantity close to the time of harvest might not warrant any further action. At a different stage in the production cycle, for example when the crop is further away from being harvested, the same infestation might require action. Consideration also has to be given to nearby and following crops is either the pest, or the remedial action going to have a consequence for the following crop. Monitoring of pests is done by regular crop walking and inspection, sticky traps are often used to monitor flying insects. The correct identification of pests is crucial and is not always easy. Cultural control measures include things like crop rotations to prevent the build up or carry over of problems; removal of infected / damaged plants; companion planting to either deter pests or as sacrificial crops to attract pests away from the commercial crop. Biological control measures include the use of: predatory mites which feed on the pest but do not damage the crop e.g. the use of *Phytoseiulus persimilis* to control red spider mite; IPM aims to ensure the most efficient use of control methods to: minimise crop damage and losses; costs of control measures; and negative environmental impacts. IPM makes good business sense. IPM is not the routine use of chemical control measures that is seen in many commercial crop production protocols.

Keywords: Integrated pest management, Horticultural Crops

EFFECT OF MICRONUTRIENTS AND PLANT GROWTH REGULATORS ON YIELD AND QUALITY OF LITCHI (LITCHI CHINESSONN.) CV. PURBI

¹MANOJ KUMAR, ²RAJESH KUMAR AND ³R.R.SINGH

Deptt. of Horticulture, MBAC, Agwanpur, Saharsa, University BAU, Sabour, Bhagalpur

The present investigation was carried out at Horticulture Garden, Bihar Agricultural College, Sabour to assess the effect of micronutrients and plant growth regulators on yield and quality of litchi cv. Purbi. Foliar spray of ZnSO₄ (0.4 and 0.8 per cent) and borax (0.2 and 0.4 per cent) was done on litchi trees before emergence of panicles, while GA₃ (10 and 20 PPM) were sprayed after completion of fruit set. The experiment was laid out in Randomized Block Design (Factorial) and replicated thrice. Maximum fruit set (42.50 per cent),

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

length of fruit (3.72cm), diameter of fruit (2.90 cm), average weight of individual fruit (20.91), number of fruit per tree (5422) and fruit yield per tree (123.10kg) was obtained with the application of borax (0.4 per cent) while interaction between borax (0.4 per cent) and GA, (20 ppm) resulted in the highest fruit retraction retention of 24.64 per cent, borax (0.2 and 0.4 per cent) also produced maximum aril percentage of 71.55 and 70.38, respectively. Various treatments of micronutrients and plant growth regulators had no marked effect on TSS content of litchi fruits. However, GA (20 ppm) and ZnSO_4 (0.4 per cent) were found most effective treatment to increase the content of reducing sugar and total sugar being the highest of 11.13 per cent and 15.90 per cent respectively. The ascorbic acid content of pulp was maximum 52 mg with ZnSO_4 (0.4 per cent) were found most effective treatment to increase the content of reducing sugar and total sugar being the highest of 11.13 per cent and 15.90 per cent, respectively. The ascorbic acid content of the pulp was maximum 52mg with ZnSO_4 (0.4 per cent) and 51.55mg with 2.4 D (10 ppm).

Thus borax (0.4 per cent) was provided to be the most efficacious treatment for increasing fruit yield of litchi while ZnSO_4 (0.4 per cent), GA, (20ppm) 2, 4 D (10 ppm) may be used as a tool for quality improvement of litchi fruit.

EFFECT OF NITROGEN ON SPINACH LEAF PRODUCTION**DR MANOJ KUMAR SINGH***Department of Horticulture, kulbhaskar Ashram Post Graduate College, Allahabad.*

Experiment was carried out at the Department of Horticulture, kulbhaskar kulbhaskar Ashram Post Graduate College, Allahabad during 2015-16. On spinach cultivar Pusa Harit. Nitrogen was applied in the form of Urea . Three levels that is one percent, 1.5 per cent, 2 % of Urea and three stages that is 10, 20 , 30 days after sowing were tried to increase biomass of spinach. Higher level of Urea at all the three stages increase the maximum leaf lamina but chlorophyll was observed disintegrated and instead of dark green , the leaf become pale green colour which is uneconomical for marketing purposes. 1.5 percent urea at all the three stages proved best with higher biomass and intense green colour. One percent urea at all three stages could not result as better as 1.5% urea at all the three stages. Control was worst in terms of yield and quality both .

EFFECT OF CORN FLOUR AS LOW COST GELLING AGENT FOR MICROPROPAGATION OF STRAWBERRY (FRAGARIA × ANANASSA DUCH.)**MANOJ KUMAR* MANOJ KUMAR*****Department of Horticulture, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P)*

Strawberry (*Fragaria × ananassa* Duch.) is a natural hybrid of *Fragaria chiloensis* and *Fragaria virginiana* which belongs to the family *Rosaceae*. The berry is delicate in flavour and rich source of vitamins particularly vitamin-C, vitamin-B1, vitamin-B2 and minerals such as calcium, potassium, copper, iron. It is a rich source of natural antioxidant which is used of hour to scavenge the free radicals as oxidants flowing in our blood to cause injurious effect to one or other organ of the body. Totipotency is a capability indicating that plant cells, in different times, may express the potential to form a new multi cellular individual. Micro-propagation technique is being exploited for many fruit crops. Corn flour, a processed (gelatinized) edible starch obtained from a plant called maize (*Zea mays*) was successfully used as a gelling agent in culture medium. Corn flour provided a firm gelling surface through out the entire culture period, and fostered optimum plantlet growth in terms of shoot height and number of leaves. The present study was undertaken in the Tissue Culture Laboratory, Department of Horticulture, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P) concentrations of corn flour as gelling agent viz; 10, 20 & 30 gm/litre. The efficacy of corn flour-gelled (30 gm) medium was studied in strawberry variety Chandler during micropropagation and minimal growth conservation. The study showed that corn starch could be used as a substitute to agar in culture medium to substantially reduce the medium cost.

EFFECT OF INTERGRATED NUTRIENT MANAGEMENT ON GROWTH AND YIELD OF ONION (ALLIUM CEPA) CV. AFLR**MANOJ PANDEY, YOGESH SINGH AND OMPAL SINGH***Department of Agricultural Chemistry and Soil Science, Raja Balwant Singh College, Bichpuri, Agra (U.P.) 283105*

Onion (*Allium cepa* L.) belongs to the family alliaceae is one of the most important commercial vegetable crops grown in India. Increasing productivity of onion with high quality is an important target by the onion growers. Onion has culinary, dietary and medicinal importance in daily life of Indian people and due to its export trade, it is also a major vegetable crop to gain foreign currency. In recent years it has been realized that judicious application of nutrients including chemical fertilizers, organic manures along with bio fertilizers (INM) are essential for quality yield and production of the crop which also overcome the problems of ecological imbalance and high cost of production. Keeping, these facts in mind the present experiment was carried out at the research farm of Raja Balwant Singh College, Bichpuri, Agra during 2016 - 17 under- semi arid and tropical climate with hot dry summer and hardy cold winter having sandy loam, slightly alkaline soil (7.85 pH). The experiment was laid out in randomized block design (R B D) having eight treatment combinations

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

i.e. T₁, recommended dose of fertilizer (R D F) 100 : 50 : 50 kg N P K per hectare, T₂-100% R D F + Azotobacter, T₃- 100% R D F + F Y M, T₄-100 % R D F + Azotobacter + F Y M, T₅- 80% R D F + Azotobacter + F Y M, T₆- 80% R D F + F Y M, T₇- 80% R D F + Azotobacter and T₈- control which was replicated thrice. The 45 days old seedlings of onion variety Agri found light red (A F L R) were transplanted at the distance of 15 x 10 cm (row x plant). On the basis of the data recorded during experimentation it was found that the vegetative growth, yield and quality of onion were significantly improved by application of different treatment combinations as compare to control. The maximum plant height (50.14 cm), no. of green leaves (6.25), fresh weight of bulb (84.32 g), bulb yield (339.58 q / ha) as well as bulb diameter (6.90 cm) were recorded with application of 100% R D F + Azotobacter + F Y M (T₄) followed by T₃ (100% R D F + F Y M) and T₅ (80% R D F + Azotobacter + F Y M). Whereas, the minimum values of above observations were found under control (T₈). The maximum net return and cost benefit ratio (1 : 2.24) was also calculated with T₄ treatment combination. Hence, it is concluded that combined use of 100% RDF + FYM + Azotobacter was the most appropriate nutrient management for higher productivity and profitability of onion under Agra region.

GROWTH AND PHOTOSYNTHETIC PIGMENTS OF BROCCOLI AS INFLUENCED BY FOLIAR APPLICATION OF MELATONIN

MANSHAGUL, F.A. KHAN, S. NARAYAN AND AJAZ A. MALIK

Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar 190025, Distt. Srinagar (J&K)

Investigation was carried out at the division of Basic Sciences and Humanities during 2017 to investigate the effect of foliar application of melatonin on plant growth and photosynthetic pigments in broccoli. Thirty days old and uniform seedlings of broccoli cv. Palam Samridhi were transplanted in the field at a spacing of 45 × 45cm. Different concentrations of melatonin, viz 0, 20, 40, 60 and 80ppm were sprayed on the plant foliage at 15 days after transplanting (DAT) replicating each treatment four times. Growth and growth analysis parameters in terms of plant height, plant dry weight, NAR, AGR, RGR, CGR and LAI were recorded at specified time intervals. Treatments were also evaluated for photosynthetic pigments viz. leaf chlorophyll and carotenoid contents. Results indicated that foliar application of different concentrations of melatonin significantly improved the growth and photosynthetic attributes wherein Mel 60ppm resulted in highest plant height (25.0 and 36.5cm), plant dry weight (24.7 and 42.5g/plant) and leaf carotenoid (0.025 and 0.028mg/g) at 30 and 60DAT. However, leaf chlorophyll content was maximum (0.69 and 1.43mg/g) with Mel 80ppm at respective days. Mel 60ppm again recorded better LAI (2.6), NAR (0.10g/cm²/day), AGR (0.47g/day) and CGR (3.84g/m²/day) compared to other levels. Present study concluded that foliar application of melatonin in broccoli played significant role in improving the plant growth, photosynthetic pigment contents and photosynthesis measured in terms of net assimilation rate. Among various concentrations Mel 60ppm proved as the best concentration for improving growth and photosynthetic pigments in broccoli cv. Palam Samridhi and increased melatonin level above 60ppm in broccoli may not be fruitful.

RESPONSE OF BIO-FERTILIZERS ON THE PERFORMANCE OF SUGAR BEET (BETA VULGARIS L.) CV. DETROIT DARK RED.

MANVENDRA SINGH SOLANKI, ROSHAN KUSHWAH, AND DALVEER SINGH

Department of Horticulture R.B. S. College, Bichpuri, Agra

The Sugar beet (*Beta vulgaris*) belongs to the family *Chenopodeaceae* which is a herbaceous biennial and winter vegetable crop. It is native to central and southern Europe and has now spread all over the world. It is a newly introduced modified root crop in our country. Sugar beet has considerable nutritive value compared to other cole crops that we commonly use in our daily diet. The fleshy root and young leaves are the main edible portion. Keeping these importance's the present study was under taken at the Department of Horticulture Raja Balwant Singh College, Bichpuri, Agra during 2017-2018.

The experimental variety D.D.R. was sowing at the distance of 40 X 10 cm. The trails have 8 treatment combinations viz. T1(Control No organic No fertilizer), T2(Full dose of RDF), T3(50%RDF+FYM), T4(50%RDF+ FYM+Azotobacter), T5(60%RDF+FYM), T6(60%RDF+FYM+Azotobacter), T7(80%RDF+FYM) and T8(80%RDF+FYM+Azotobacter). The experiment was conducted under Randomized Block Design which was replicated three times.

On the basis of data recorded during experimentation it was found that significant effect among treatment and maximum inhance in plant height (17.66 cm), total no. of leaf per plant (13.22), the number of fully opened leaves per plant (9.89), length of the largest leaves (22.67cm), width of the largest leaf (9.9cm) and fresh weight of leaf per plant (9.86) at harvest. Besides, the fresh weight of root (356.66gm), length of the whole root (10.04cm), diameter of storage root the shoulder point (7.38cm) and total root yield 364.27 Q/ha. Were recorded under T8 (80%RDF+FYM+Azotobacter) followed by T6 (60%RDF+FYM+Azotobacter).

LAND SUITABILITY ANALYSIS FOR AGRICULTURAL CROPS**MARIYA*, QURAT SHEIKH, ASIF YOUSUF WANI, RAHEEBA-TUN-NISA, MAKHDOOMI FARAH***¹Division of Soil Science and Agricultural Chemistry, FOA, Wadura, SKUAST-K*

Soil is a very important natural resource that supports various life systems therefore, it needs to be harnessed keeping in view its potential. Soil provides nutrients and also acts as a store of water for plant growth. Crop productivity highly depends upon the soil conditions. There are many soil health indicators that measure various physical, chemical and biological attributes which relate to functional soil processes. Hence an evaluation needs to be carried out to assess the performance of land for specific use. Land has now become one of the limited resources as the productivity of soils has decreased worldwide. The challenge is thus being faced not only of increasing productivity on sustainable basis, but also of preserving and maintaining of soil resource bases for prosperity. The ability of land to produce is limited and also affected by various factors. Despite the significant growth in production, the sustainability of some cropping systems has been showing signs of fatigue. Therefore, different measures have to be adopted and executed according to the capability of a particular soil. The resources need to be managed and used in such a way that without diminishing their potential for future use they meet the needs. Comprehensive account of our land resource ascertaining its potential and problems towards optimising land use on sustainable basis is necessary. In recent past, concept of land based holistic development has emerged as one of the potential approaches which can lead to a higher productivity and sustainability in agricultural production. Soils need to be interpreted in terms of their suitability for alternative land use especially in respect of their land capability and suitability for crop growth. The research focuses on addressing uncertainty in the process of land suitability analysis for agricultural crops using remote sensing and GIS techniques.

Keywords: suitability, capability, sustainability, land, productivity

PERFUSION OF ZNO NANOPARTICLES FOR THE MANAGEMENT OF PHOMOPSIS VEXANS AND RALSTONIA SOLANACEARUM ON SOLANUM MELONGENA**MASUDULLAKHAN, M. R. KHAN, L. AHMAD AND Z. A. SIDDIQUI***Section of Plant Pathology and Nematology, Department of Botany, Aligarh Muslim University, Aligarh-202002*

Effect of zinc oxide nanoparticle (ZnO NPs) was observed on *Phomopsis vexans*, *Ralstonia solanacearum* and on the growth of brinjal in pot experiment. Perfusion of plants with 10 ml solution of ZnO NPs with 250, 500 and 1000 ppm concentration caused a significant increase in chlorophyll, carotenoid and plant dry weight over control. Inoculation of plants with *P. vexans* and *R. solanacearum* caused a significant reduction in plant growth and dry weight over uninoculated control. Perfusion of plants with 250, 500 and 1000 ppm ZnO NPs and subsequent inoculation with *P. vexans* and *R. solanacearum* caused a significant increase in plant growth and dry weight over plants inoculated without perfusion of ZnO nanoparticles. Treatment of 1000 ppm ZnO NPs caused a greater increase in plant dry weight of *P. vexans* and *R. solanacearum* inoculated plants followed by 500 ppm and 250 ppm. Blight indices and wilt indices were reduced to 4, 3 and 2, respectively, when plants with *P. vexans* and *R. solanacearum* were treated with 250, 500 and 1000 ppm ZnO NPs. This study shows that the use of ZnO nanoparticles is useful for the management of *P. vexans* and *R. solanacearum* on brinjal.

Key words: *Phomopsis vexans*, *Ralstonia solanacearum*, ZnO nanoparticles, *Solanum melongena*.

MOLECULAR AND PHENOTYPIC ANALYSIS FOR YELLOW RUST IN WHEAT VARIETIES**MEDHAVI VASHISTH***Department of Molecular Biology, Biotechnology and Bioinformatics, CCS Haryana Agricultural University, Hisar (Haryana)-125004, INDIA*

Stripe rust is one of the most destructive diseases of wheat. Breeding for resistance is the most economical and environmentally acceptable means to control stripe rust. The present investigation "Phenotyping and microsatellite marker analysis for yellow rust in WH711 × WH542 F₂ population of wheat (*Triticum aestivum* L. em. Thell)" was carried out to evaluate F₂ population derived from WH711 and WH542 varieties of wheat for traits contributing to yield and to identify presence of markers linked to yellow rust. WH542 (resistant to yellow rust) × WH711 (susceptible to yellow rust) derived F₂ population when screened against yellow rust reaction, showed a ratio of 9:3:3:31 suggesting the additive gene effect controlling the respective trait. Correlation analysis revealed that biological yield (0.891) had the highest direct contribution towards grain yield per plant followed by number of tillers per plant (0.816). Out of 50 SSR markers used, 39 showed amplification, of which 17 SSRs were polymorphic while 22 were monomorphic. Microsatellite marker data was generated using 17 polymorphic SSR markers (including 3 Yr specific markers). However, none of the SSR markers used in the present study showed any association with yellow rust resistance. This indicated that resistance in WH542 may be either due to different genes or different mechanisms or new combinations of these which require further investigation.

PERFORMANCE OF WHEAT UNDER VARIOUS COMBINATIONS OF PHOSPHORUS APPLICATION IN RICE-WHEAT CROPPING SYSTEM IN GOBRAILA, KAILALI, NEPAL**MEENA KUMARI POUDEL, AGRICULTURE AND FORESTRY UNIVERSITY, RAMPUR, CHITWAN, NEPAL 2018**

A field experiment was conducted at Gobraila, Kailali during winter season of 2017/18 to study the performance of wheat under various combinations of phosphorus application in rice-wheat cropping system. The experiment was done in Randomized complete block design having four replications and five treatments. The experiment consisted of various combinations of phosphorus application (kg ha^{-1}) in rice followed by wheat as P_{50-0} , P_{0-50} , P_{50-50} , P_{25-25} and P_{0-0} with recommended dose of nitrogen and potassium fertilizer application. Vijay variety of wheat was used in the study. Phosphorus application in both rice and wheat either full dose or half dose significantly increased plant height, NDVI and number of grains per spike of wheat over control and also caused the early heading of wheat. However, grain yield of wheat was not significantly influenced by various combinations of phosphorus application in R-W cropping system. Indeed, yield advantage of 17.10 percent and 16.45 percent in wheat grain was recorded from 50 kg P ha^{-1} and 25 kg P ha^{-1} application in both rice and wheat over control plot. Similarly, from the comparative economic analysis done between half dose and full dose of phosphorus application, yield obtained from 25 kg P ha^{-1} application in both rice and wheat was found to be economic optimum dose. Hence, half dose of phosphorus application in both rice and wheat exhibited better performance of wheat in Gobraila, Kailali under R-W cropping system.

Keywords: Phosphorus, R-W cropping system, Grain yield, Yield attributes

INTEGRATED NUTRIENT MANAGEMENT IN RICE: A STEP TOWARDS SUSTAINABILITY**MEENAKSHI RATHI¹ AND ANNIE KHANNA²**

¹Dept. of Genetics and Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar (Haryana) 125001, ²Dept. of Plant Pathology, Chaudhary Charan Singh Haryana Agricultural University, Hisar

Rice is the most important human food crop, directly feeding more than half of the population of world. Global rice production more than tripled between 1961 and 2010, with a compound growth rate of 2.24% per year due to introduction of dwarf varieties which are more responsive towards fertilizer dose. States like Punjab and Haryana use a very high amount of synthetic fertilizers in rice-wheat rotation, as both of these crops are high nutrient consumers and leave soil exhausted. In such condition Integrated Nutrient Management can be best option. INM refers to the maintenance of soil fertility and plant nutrient supply at an optimum level through optimization of the benefits from all possible sources of organic, inorganic and biological components in an integrated manner. Bajpai *et al.* (2006) found that grain yield of rice was highest, when 50% of nitrogen was supplied through green manuring (GM) whereas when 50% of N was supplied through farmyard manure (FYM), the yield was same as when 100% of NPK had been applied through chemical fertilizers. Incorporation of organic sources considerably improved the soil properties such as decrease in bulk density and increase in infiltration rate and available NPK status of the soil for the wheat crop in rabi season. Inclusion of short duration pulse crop (mungbean) in the system not only produced 11.0 q ha^{-1} additional income before rice transplanting but also substituted for 50 per cent of recommended NPK fertilizers in rice (Bhandari *et al.* 1992). Quantity of nitrogen and phosphorous fertilizers can be reduced to half of the recommended dose with the application of *Azotobacter* and phosphorous solubilizing bacteria (PSB) along with FYM or vermicompost or green manuring. Application of FYM, green manuring, vermicompost and rice residue in combination with biofertilizers supplemented by NPK fertilizers improved the soil fertility and maintained higher sustainable productivity (Singh *et al.* 2008). All these studies show that instead of using only synthetic fertilizers, INM can help us to maintain the productivity as well as soil health for a sustainable development.

STUDY ON BIOLOGY OF RICE WEEVIL, *SITOPHILUS ORYZAE***MEGHA. G**

Department of Entomology, SVPUA&T, Modipuram, Meerut, 250110 (UP)

The rice weevil, *Sitophilus oryzae* (Coleoptera: Curculionidae), is one of the most destructive pests of stored cereals. Knowledge of the life history and biology is important for the development of an integrated pest management program. Investigation includes egg incubation, oviposition periods, and larval instar development under ambient temperature of $28 \pm 2^\circ \text{C}$ and $75 \pm 5\%$ relative humidity. Maize seeds with rice weevil are reared, eggs so obtained will be maintained in a plastic container for incubation. Daily 20 grains, from the day of oviposition to egg hatching will be observed to determine the incubation period. On hatching the larvae of rice weevil are allowed to feed inside the seed. 20 grains per day will be dissected to observe the different stage of larvae. Larval instars are determined by the presence of moulted skin and range of head capsule width. Dissection of the maize seeds will be continued till the appearance of pupal stage. Twenty seeds with eggs of rice weevil obtained will be dissected out daily till the emergence of adults. Pupal period will be determined by subtracting incubation and larval period. Ten pairs of adults will be released individually in plastic container (10 cm diameter) to observe pre-mating and mating period. The mated females will be taken and kept in a plastic container (10 cm diameter) along with the maize seeds to know the pre-oviposition and oviposition periods. The life span of rice weevil adults will be observed by enclosing male and female adults in a plastic container.

CORRELATION AND PATH COEFFICIENT ANALYSIS IN FINGER MILLET (*ELEUSINE CORACANA*(L.) GEARTN) MAHANTHESHAM^{*1}, M. SUJATHA² ASHOK KUMAR MEENA³ AND S. R. PANDRAVADA⁴

^{1,2,3} *Department of Genetics and Plant Breeding, College of Agriculture, Rajendranagar, ANGRAU, Hyderabad-30*

⁴ *National Bureau of Plant Genetic Resources, Rajendranagar, Hyderabad -30*

A field experiment was conducted to carry out yield component analysis through correlation and path analysis. Forty eight genotypes of finger millet were sown in a randomized block design with three replications, during *kharif* 2014 at National Bureau of Plant Genetic Resources research field, Rajendranagar, Hyderabad. The objective of the experiment was to assess the nature of interrelationships and direct and indirect effect of different yield contributing traits towards grain yield. From correlation studies it was observed that grain yield per plant has exhibited significant positive association with total no. of basal tillers per plant, productive tillers per plant, total fingers on the main ear, finger length and finger width. Path analysis revealed that maximum positive direct effect on grain yield per plant was exhibited productive tillers per plant followed by Finger length, Finger width. Therefore, it is emphasized to lay attention on traits like productive tillers per plant followed by Finger length, Finger width while selecting for improvement in grain yield of finger millet.

Key Words: Finger millet, correlation, path analysis, yield contributing traits.

USE OF SEED BIO-PRIMING FOR PLANT DISEASE MANAGEMENT.

MEHJABI HASHMI¹; SHAHNASHI HASHMI²; ANAND SHUBHAM PANDEY³; DIPANJALI BAG⁴

Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut-250110, U.P., India, Institute of Agriculture Science, Bundelkhand University, Jhansi-284003, U.P., India, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut-250110, U.P., India, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut-250110, U.P., India

Soil contamination and environmental hazard from the indiscriminate and excessive application of agrochemicals on crops have been key issues for the present-day agriculture. Additionally, the risk to human health has also led to stringent regulatory framework around the use of synthetic chemicals in agriculture. Bio-inoculants have emerged as the most feasible eco-friendly solution to these issues and have been gaining considerable consumer acceptance since the time they were first introduced. Bioagents are substances containing living microorganisms which promote plant growth and maintain the soil and crop health by increasing the supply or availability of primary nutrients to the host plant. Bio-priming which involves seed priming in combination with low dosage of beneficial microorganisms is becoming a potentially prominent technique to induce profound changes in versatility of plant performance, encourage desired attributes in crop growth, and stabilize the efficacy of biological agents in the present fragile setup of agriculture by reducing dependency on chemical inputs and offers an attractive option for resource-poor farmers being an easy and cost effective method. The most prominent contributors in fungi and bacteria which are used extensively in bio-priming include *Trichoderma*, *Pseudomonas*, *Glomus*, *Bacillus*, *Agrobacterium*, and *Gliocladium*. Bio-priming has a great potential for improving crop growth and nutrient use efficiency.

QUALITY PARAMETERS OF CARMEN PEAR AS AFFECTED BY FOLIAR APPLICATION OF SALICYLIC ACID AND CALCIUM CHLORIDE

MEHNIGAR HAMID, ANGREJ ALI^{*}, AMIT KUMAR, SUMAYAMUMTAZ, SHABNAMAHAD AND SHAHIDAASHRAF

*Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K), *Division of Horticulture, FOA, SKUAST-Kashmir, Wadura Campus, Sopore (J&K)*

Salicylic acid and Calcium chloride was applied through foliar spray and physio-chemical quality of Carmen variety of pear was assessed. The experiment was carried out on five year plants of Carmen pear grafted on Quince C rootstock at Experimental Farm of Division of Fruit Science, SKUAST-Kashmir, Shalimar campus, Srinagar (J&K) during 2017. Treatments consisted of four levels of salicylic acid (0, 1 and 2 ppm) and four levels of calcium chloride (0.2, 0.25 and 0.3 %) constituting total sixteen treatment combinations. The experiment was laid out in Randomised Complete Block Design with factorial arrangements and replicated thrice. The treatments were applied as foliar spray at 3, 6 and 12 weeks after petal fall. Results revealed that the exogenous application of salicylic acid had significant effect on physico-chemical quality of the pear. Maximum fruit weight (168.44g), fruit volume (146.00), fruit length (10.03cm), fruit breadth (6.70 cm), firmness (10.16 kg/cm²), TSS (14.04° Brix), ascorbic acid (9.41 mg/100g), reducing sugars (11.04%) and total sugars (12.97 %) and acidity (0.54%) was recorded with salicylic acid @ 200ppm. Calcium chloride 0.3 per cent also enhanced the physico-chemical quality of the fruits compared with control, wherein maximum fruit weight (165.00 g), fruit volume (145.42), fruit length (10.00 cm), fruit breadth (6.67 cm), firmness (10.18 kg/cm²), ascorbic acid (9.42 mg/100g), and acidity (0.52%) was recorded with calcium chloride 0.3 per cent. It is therefore concluded that the salicylic acid @ 200ppm and calcium chloride @ 0.30% improved fruit quality.

ROLE OF PLANT GROWTH REGULATORS IN TEMPERATE FRUITS UNDER HIGH DENSITY PLANTATION**MEHNIGAR HAMID, ANGREJ ALI*, AMIT KUMAR, SUMAYAMUMTAZ, SHABNAMAHAD AND SHAHIDAASHRAF***Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K), *Division of Horticulture, FOA, SKUAST-Kashmir, Wadura Campus, Sopore (J&K)*

Plant growth regulators (PGR) include naturally occurring plant growth substances or phytohormones, as well as synthetic compounds which are mostly chemical analogs, materials that alter hormone levels and materials that alter hormone sensitivity. Since 1940's both natural and synthetic growth regulators have been used in horticulture with increasing incidence to modify crop plants by controlling plant developmental processes, from germination to post harvest preservation (Basra, 2000). The concentrations, time and method of application plays an important role in determining the effect of these chemicals on various fruit crops and now are used in High Density Orchards for various aspects like control of vegetative growth, fruit set, thinning, mitigate alternate bearing, good fruit quality and post-harvest management. Plant bio-regulators helps in formation of good architecture which will enhance better quality fruit production. Some growth retardants like SADH, CCC, MH, Prohexadione calcium, paclobutrazol can be used to control vegetative growth and some PGRs like Promalin induce branching. Prohexadione calcium significantly decreases the shoot growth in apple cv. Gala. Auxins, cytokinins, gibberellins and some growth retardants are reported to increase fruit set. Gibberellins increase fruit set, fruit number and yield in pear cv. Beurrue Bosc and Triumf. Plant Growth Regulators viz. 6-Benzyladenine and naphthalene acetic acid reduces the crop load in Golden Delicious and increase fruit size > 70 mm size. Auxin in dose 0.7 l/ha at the beginning of pit-hardening stimulated cell enlargement in the mesocarp of 'Regina' cherry fruit, which in turn, caused a significant improvement in fruit size. Salicylic acid treatments significantly retained firmness, total soluble solids, ascorbic acid content and weight loss in Jonagold apple compared to the control. Therefore, detailed knowledge and understanding of hormone biosynthesis, transport, mechanism of action, rate, time and method of application are required to predict any specific response in fruit crops in different climatic conditions.

ANALYSIS OF GENETIC COMPONENTS OF IMPORTANT TRAITS IN OKRA (*ABELMOSCHUS ESCULENTUS* (L). MOENCH.)**MEKALASRIKANTH*, S.K DHANKHAR AND MAMATHAN.C***¹Department of Vegetable Science, CCSHAU, Hisar, Haryana.*

The experiment was carried out during *kharif* season 2015, spring summer and *kharif* seasons of 2016, at the Vegetable Research Farm of the Department of Vegetable Science, CCS HAU, Hisar. *Four F₁ hybrids namely*, Hisar Naveen x Varsha Uphar, HB 25-2 x HB-32, HB-40 x HB-27 and HB-1157 x Pusa Sawani *developed and sown in Compact Family Block Design to evaluate them for growth, yield and its traits*. During present study, most of the crosses for all the yield traits showed low magnitude of dominance and higher environmental variances, revealing lower estimates of narrow-sense heritability. The additive component contributed a large proportion of the variation for plant height in cross HB-40 x HB-27, fruit diameter in cross Hisar Naveen x Varsha Uphar and for number of fruits per plant in cross HB-1157 x Pusa Sawani. The average dominance ratio was more than unity for plant height, first fruiting node and number of fruits per plant (Hisar Naveen x Varsha Uphar and HB-25-2 x HB-32), for inter-nodal length (Hisar Naveen x Varsha Uphar and HB-1157 x Pusa Sawani), for fruit length (Hisar Naveen x Varsha Uphar, HB-25-2 x HB-32 and HB-1157 x Pusa Sawani), for fruit weight in all four crosses, for fruit yield per plant (Hisar Naveen x Varsha Uphar and HB-40 x HB-27), which showed the importance of the dominance gene effects that is in agreement with low narrow sense heritability for these traits. Narrow sense heritability was observed low to high for all traits and ranged from 0.59 to 68.04 depending on the trait and cross combination. Estimates of narrow sense heritability indicated that additive effects were primarily responsible for the genetic variation in these hybrids.

Key words: Additive, dominance, heritability and variance

AGRICULTURE AND UN SUSTAINABLE DEVELOPMENT GOALS**MOHDASHAQ MALIK***Department of Botany, Govt. PG College, Rajouri, J&K -185131*

Based on the success of Millennium Development Goals, the United Nations on September 25th, 2015 adopted a new set of 17 Sustainable Development Goals (SDGs) with 169 targets and 304 indicators. The global goals which together are called Agenda 2030 officially came into force on 1 January 2016. The Goals that universally apply to all nations, will mobilize efforts to end all form poverty, hunger, fight inequalities and tackle the alarming climate change and bring overall peace and prosperity as well as equitable and sustainable development of people on planet over next 15 years. Although the SDGs are not legally binding, countries were expected to take ownership and establish national frameworks for the achievement of these Goals.

As per the SDGs report 2018, progress has been recorded on several fronts, yet a large number of areas where comprehensive efforts are required to achieve the goals. The rate of extreme poverty has fallen rapidly: but as per latest global estimate 11 per cent of the world

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

population, or 783 million people, lived below the extreme poverty threshold in 2013. World hunger is also on the rise again: 815 million people were undernourished in 2016 which are up from 777 million in 2015. Aid to agriculture in developing countries totalled \$12.5 billion in 2016, falling to 6 per cent of all donors. Conflict, drought and climate change are the key factors to increase world hunger and food insecurity. Agriculture is central to all the goals so far sustainable peace and development is concerned. No doubt, more than any other sector, agriculture is the common thread which holds the 17 SDGs together. If investigated diligently in Agriculture by improving plant health, and mobilising scientific, technological and social movements, the challenges of extreme poverty and hunger can considerably be reduced by world society. In the present study an attempt has been made to investigate, how investing in the agricultural sector can address the challenges of not only hunger, malnutrition and poverty but also disease, illiteracy, clean water, energy, sustainable production and consumption, and climate change.

PERFORMANCE OF VARIETIES AND ROW SPACING ON YIELD, QUALITY AND ECONOMICS OF SAFFLOWER (*CARTHAMUS TINCTORIUS* L.)

MIRZAI.A.B, GOKHALE D.N., PAWAR S.U. AND SHAIKH WASIM CHAND

Department of Agronomy, College of Agriculture, VNMKV, Parbhani.

A field experiment was conducted during the *rabi* season of 2015 at AICRP on safflower, V.N.M.K.V., Parbhani with a view to find out the suitable row spacing for safflower on seed yield, oil content, oil yield and economics of safflower. The experiment was laid out in factorial randomized block design with five spacing S_1 -30 cm x 20 cm, S_2 -45 cm x 20 cm, S_3 -60 cm x 20 cm, S_4 - 75 cm x 20cm, S_5 - 90 cm x 20 cm. and two varieties Annegeri -1 (V_1) and NARI- 38 (V_2) in three replications. Each experimental unite was repeated three times 5.4 x 4.0 m² size in gross plot and it was of 4.5 x 3.6 m² size in net plot. From the result of experiment can be concluded that among different varieties of safflower Annegeri -1 produced significantly higher yield attributes, higher gross monetary returns, net monetary returns and B: C ratio followed by NARI-38 (V_2). The variety Annegeri-1 (V_1) produced significantly higher yield and yield attributes, higher gross monetary returns, net monetary returns and B: C ratio when sown with S_2 -45 cm x 20 cm. Sowing of safflower at S_2 -45 cm x 20 cm spacing was found better for higher yield and economics was followed by S_1 -30 cm x 20 cm. The interaction effects of varieties x spacings were found to be non- significant.

IMPACT OF SAFFLOWER (*CARTHAMUS TINCTORIUS* L.) VARIETIES UNDER DIFFERENT ROW SPACING ON GROWTH AND YIELD

MIRZAI.A.B, AWASARMAL V.B., SHAIKH WASIM CHAND AND KHAZI G.S.

Department of Agronomy, College of Agriculture, VNMKV, Parbhani.

A field experiment entitled "Performance of safflower (*Carthamus tinctorius* L.) varieties under different row spacing" was conducted during the *rabi* season of 2015 at AICRP on safflower, V.N.M.K.V., Parbhani with a view to find out the suitable row spacing for safflower on growth, seed yield, oil content and oil yield of safflower. The experiment was laid out in factorial randomized block design with five spacing S_1 -30 cm x 20 cm, S_2 -45 cm x 20 cm, S_3 -60 cm x 20 cm, S_4 - 75 cm x 20cm, S_5 -90 cm x 20 cm. and two varieties V_1 - Annegeri -1 and V_2 - NARI- 38 in three replications. Each experimental unite was repeated three times 5.4 x 4.0 m² size in gross plot and it was of 4.5 x 3.6 m² size in net plot. From the result of experiment can be concluded that among different varieties of safflower Annegeri -1 (V_1) produced significantly higher growth characters and yield followed by NARI-38 (V_2). The variety Annegeri -1 (V_1) produced significantly higher yield when sown with S_2 -45 cm x 20 cm. Sowing of safflower at S_2 -45 cm x 20 cm spacing was found better for higher yield was followed by S_1 -30 cm x 20 cm. The interaction effects of varieties x spacings were found to be non- significant.

INTEGRATED PEST MANAGEMENT IN ORGANIC FARMING

MITHLESH KUMAR PANDEY¹, SATY SARAN², ARVIND SINGH³, VISVASH VAIBHAV⁴

¹ Department of Agriculture: Innocent Heart Group of Institute, Punjab, ^{2,3,4}Department of Entomology : SVPUA&T, Meerut (UP) 250110

One of the greatest challenges of the 21st century is the need to feed a growing population. Integrated Pest Management and organic production methods can work together to address this vital challenge. A definition adopted by the International federation of Organic Agriculture Movements in 2008; organic agriculture is "A production system that sustains the health of soils, ecosystems and people. Organic agriculture combines tradition, innovation and science to benefit the shared environment and promote fair relationships and a good quality of life for all involved. Application of fertilizers either in organic or inorganic form influences the host plant growth and also exerts considerable influence on diseases, insects and their natural enemies. Organic manures supply both macro and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

micronutrients and helps in build up of resistance of plants to insect attack. The use of organic amendments in pest management is considered an ecologically viable proposition which avoid environmental pollution. It affects the quality and marketable yield of many agricultural crops. Sources of organic products are Mustard cake, Neem cake, Niger cake, Pungam cake, Rape seed cake, Safflower cake, Sesame cake, Castor cake, Coconut cake, Cotton seed cake, Dhupaka cake, Ground nut cake, Decorticated Under corticated Jambo cake. Karanj cake. Linseed cake and some Insecticides permitted in organic agricultural Vermi compost produced through the breakdown of organic matter by earthworms and microorganisms can be used as an amendment to strengthen the plant and reduce pest levels. Vermicompost is high in microbial diversity, contains considerable amount of humic substances and increases host plant resistance to pests, including aphids, Mealybugs, and spider mites. Organic crops that are grown in fertile soils with high organic matter and active soil biology generally exhibit a lower abundance of several pests due to lower nitrogen content. Some microbial insecticides containing the bacteria *Bacillus thuringiensis*. Three main strains of these bacteria are used in insect control. Botanical insecticides, such as rotenone, are also permitted in organic agriculture, but they are often too expensive to use on large acreages. For pest control beneficial organisms, dormant oil, diatomaceous earth. Plant-derived pesticides, soap, natural and synthetic insect pheromones which disrupt the insect's development. and commercial insect vacuums can be used. Various naturally occurring substances and products e.g. Neem, Pongamia, NPV, *Trichogramma*, *Trichoderma* etc. Herbal extracts should be used only as a final remedy only after utilizing practicing all the above said methods in organic farming.

Keywords : Integrated Pest Management, Organic Farming, Botanicals

INCREASING ECONOMY AND FARMER'S INCOME BY CONTROLLING THE EFFECT OF BIOTIC AND ABIOTIC FACTORS ON SHELF LIFE OF KANGRA TEA

MITTU KATOCH^{1*}, PARMOD VERMA, SATYANARAYAN MALLADI MURTHY AND RAJJU PRIYASONI

Lovely Professional University, Phagwara, Punjab., ²Assistant professor and ⁴Senior Research fellow, CSKHPKV, Palampur.

Tea, *Cammelia sinensis*, is one of the oldest and non-alcoholic beverages used in the world. It is available for consumption in six main variants, based on the oxidation/fermentation technique applied during processing. Black and green tea is the most common form of made tea. Basically commonly known but completely ignored problem of tea i.e. the effect of different packaging material (Flipovic. et al., 2009) on the shelf life (Debnath *et. al* 2012) of the Kangra tea and seasonal impact on tea. This study proves to be quite useful in respect of variety, durability, cost, production and economic status of the tea. As we aware, that tea is used worldwide as a beverage once or thrice a day. Shelf life is the important aspect on the storage of tea because quality and also the large quantity of stored made tea available at home get spoiled due to the non-availability or lesser knowledge about the best packaging material of tea against different seasonal variations and packaging problems (Gimenez et al., 2003). If this problem is solved then it is a better solution for society and also it strengthens the economy of India. The study is planned with objectives *viz.* 1. To study the impact of different packing material on the shelf life of Kangra Tea. 2. To study the seasonal impact on the shelf life of Kangra tea. and 3. Isolation and identification of different biotic factor responsible for the degradation of packed tea. Research work will be carried out through site selection, sample collection, from Palampur tea cooperative factory at three different growing seasons of tea in a different type of packaging materials. Various microbial parameters shall be tested in the laboratory of Crop Research laboratory of Agronomy department of CSKHPKV, Palampur and Natural Product Laboratory of IHBT CSIR Palampur of Kangra district (H.P.).

IMPACT OF LONG-TERM BALANCED AND IMBALANCED USE OF FERTILIZERS ON SOIL QUALITY AND PRODUCTIVITY IN RICE-WHEAT CROPPING SYSTEM

M.K. BHATT¹, K.P. RAVERKAR¹, RAMESH CHANDRA¹, NAVNEET PAREEK¹, D.K. SINGH² AND J.C. CHANDOLA³

¹Department of Soil Science, College of Agriculture, G.B.P.U.A.&T., Pantnagar, Uttarakhand, India, ²Department of Agronomy, College of Agriculture, G.B.P.U.A.&T., Pantnagar, Uttarakhand, India, ³Department of Horticulture, College of Agriculture, G.B.P.U.A.&T., Pantnagar, U.S. Nagar, Uttarakhand, India

In a continuing long-term fertilizer experiment initiated in 1984 with rice-wheat crop rotation at the A₂ block of the Norman E. Borloug Crop Research Centre of G. B. Pant University of Agriculture and Technology, Pantnagar, the impact of balanced and imbalanced fertilization for 29 years on soil quality indices and productivity of the system was evaluated during 2013-2014. Different combinations of N, P, K, Zn and FYM treatments have been maintained in fixed layout since the beginning of the experiment in a Randomized Block Design with four replications. Rice (var. Pant Dhan 4) and wheat (var. UP-2425) crops were taken during *kharif* and *rabi*, respectively. The N, P and K as per treatment details were supplied through urea, single super phosphate and muriate of potash, respectively. The treatments having FYM was received it only in rice crop i.e during *kharif*. To achieve the objectives of the study soil samples were collected from each plot from 0-15 & 15-30 cm depth after harvest of rice and wheat crops. At the end of season the yield of rice and wheat were recorded. Continuous cropping and fertilization alone and with FYM for 29 years increased the soil pH (8.16-8.19 unit), EC (0.28-0.34 dSm⁻¹) and reduced bulk density (1.28-1.39 g cm⁻¹) from their initial values of 7.9, 0.120 dSm⁻¹ and 1.33 g cm⁻¹, respectively. The

status of cation exchange capacity, organic carbon, available N, P, and K, decreased due to long-term application of inorganic fertilizer alone compared to initial status at inception of experiment, while application of NPK along with FYM maintained their status in soil. The highest organic carbon, available N and P in both the surface and sub-surface soil layers was maintained with $N_{180}+P_{80}+K_{40}+Zn(F)+FYM$ which was followed by $N_{120}+P_{40}+K_{40}+FYM$ and $N_{120}+P_{40}+K_{40}+ZnF+FYM$. Addition of FYM along with NPK also increased the level of micronutrients in soil. The highest microbial population, population of *Azotobacter* and PSB, dehydrogenase, phosphatase activity and potentially mineralizable nitrogen in both the surface and sub-surface soil layers was supported due to $N_{180}+P_{80}+K_{40}+Zn(F)+FYM$ followed by $N_{120}+P_{40}+K_{40}+Zn(F)+FYM$ and $N_{120}+P_{40}+K_{40}+FYM$. The combined use of inorganic fertilizer along with FYM for twenty-nine years significantly improved the bulk density, water holding capacity, hydraulic conductivity, mean weight diameter and aggregate stability in both the surface and sub-surface soil layers. However, the highest bulk density and particle density were obtained under control. An application of $N_{180}+P_{80}+K_{40}+Zn(F)+FYM$ supported the highest water holding capacity, hydraulic conductivity, mean weight diameter and aggregate stability while the lowest under control. As a result of improved physical, chemical, and biological quality indices of soil due to combined application of balanced dose of inorganic fertilizer and FYM for twenty-nine years, the highest productivity of rice and wheat (6747 kg ha⁻¹ and 3254 kg ha⁻¹, respectively) was recorded due to $N_{180}+P_{80}+K_{40}+Zn(F)+FYM$ followed by $N_{120}+P_{40}+K_{40}+FYM$ and $N_{120}+P_{40}+K_{40}+Zn(F)+FYM$ which was statistically at par with each other but significantly different from other fertilizer treatments. During the present investigation various physical, chemical and biological indices of soil quality after 29 years of balance and imbalanced fertilization alone or with FYM found to be significantly correlated with each other as well as productivity of rice and wheat crops. From the present investigation it can be elucidated that the combined use of chemical fertilizer along with FYM for twenty-nine years of rice-wheat cropping system is a sustainable nutrient management practice because of improved soil physical, biological and chemical indices of soil as well as their interrelationship with each other and crop yield.

^{1,3}Department of Agronomy, ²Department of Food Science and Nutrition, ⁴Department of Crop Physiology, ^{1,3}C. S. Azad University of Agriculture & Technology, Kanpur, ²Jiwaji University, Gwalior, ⁴NDUA & TKumarganj, Faizabad

A field experiment conducted during Rabi 2013-2014 at Students Instructional farm, Department of Agronomy, Chandra Shekhar Azad University of Agriculture and Technology, Kanpur (U.P.). To find out studies the effect of tillage, varieties and weed management practices on growth and yield of lentil (*Lensculinaris* Medick.) In case of Tillage use as two tillage practices like as zero tillage and conventional tillage. Second factor use of two variety like as KLS-218 and KLB- 320 and Third factor is used of weed management practices viz. different comparison of weedy control plot and second one two hand weeding (30 and 45 DAS), Third weed management practices used pendimethalin @ 1kg ai/ha in different plot. All factors are presented in double split plot design. In case of Tillage practices conventional tillage is gives more yield and low weed populations zero tillage gives as more weed population and low yield and in case of variety KLS- 218 gives higher yield comparison to KLB-320. In case other management practices, two hands weed ing gives superior results comparison to all of the factors and also give better yield potential followed by application of pendi methal in @ 1 kg ai/ha give lower yield comparison to two hand weeding. Practices where variety KLS -218 and conventional tillage along with two hand weed gnaws done give higher grain and straw yield comparison to all. Other treatments also recorded higher net income and B: C Ratio. This experiment was done where soil was sandy loam in texture. Organic carbon was about 0.5% and nitrogen content was low, medium in phosphorus and potassium availability. The P^H 7.7 indicates that the soil was slightly alkaline in reaction.

MITIGATION OF SPOT BLOTCH OF BARLEY (*HORDEUM VULGARE* L.) THROUGH AGRICULTURAL PRACTICES FOR MAXIMIZATION OF THE SEED QUALITY

MOHAMMAD AMIR

Narendra Dev University of Agriculture and Technology, Kumarganj, Faizabad 224229 (U.P.) India

Barley (*Hordeum vulgare* L.) belonging to the family Poaceae, is an annual monocotyledonous herb, tribe *Triticeae*. Barley is evolutionarily closely related to two other small-seeded cereal species, wheat and rye. India has about 7.57 lakh ha area with production of 14.72 lakh tonnes and productivity of 19.44 q/ha. In UP, barley occupied an area of 2.86 lakh ha with a total production of 6.38 lakh tonnes with productivity of 22.25 q/ha. Uttar Pradesh alone contributed more than one fourth of India's total production of barley during 2016-17. We are still below the world average in its productivity level as it is cultivated under minimum input management conditions. The demand for the malt barley from industry is on the rise which is presently nearly 18-20 per cent of the total barley production of the country. A good quality seed should maintain the viability and germination till the next sowing season. Germination of quality seed lot should be high for obtaining the desired crop stand in the field. Vigour of quality seed should be high as the vigorous seeds will stand better in the field in adverse condition. All these qualities of seeds are affected by various factors including various seed borne pathogens.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Spot blotch disease caused by the fungus *Bipolaris sorokiniana* (teleomorph *Cochliobolus sativus*) is one of the most important fungal disease of barley. Many factors including climate conditions (Rainfall, temperature and humidity) and agricultural practices influence the development and spread of disease and thus affect the seed crop. Considering quantum of losses, the investigations on management of spot blotch, for maximizing the seed quality, experiment were conducted at CRS, Masodha and Students' Instructional Farm and Seed Pathology Laboratory at Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during 2016-17 and 2017-18. Effect of date of sowing, organic and chemical amendments on disease severity was quantified during the present investigation. Effect of different nitrogen levels and treatment with Plant Growth Promoting Rhizobacteria on disease severity was studied. Also the disease management through seed treatment and fungicidal foliar sprays was tried to recommend a management schedule for bring down the disease severity, maximize seed yield and its quality. Minimum seed infection of *Bipolaris sorokiniana* (5.5%) was recorded through the crop sown in mid-November with recommended dose of fertilizers + FYM @ 5t/ha plus paddy straw mulching followed by two sprays of zinc sulphate and KCl. This treatment resulted in maximize the viability, germination, seedling length and vigour index also. Nitrogen @30 Kg/ha with seed treatment of Azatobacter plus PSB was found best for minimizing the disease and optimizing the seed quality attributes. Seed treatment with Vitavax Power @ 2.0 g/kg seed and two foliar sprays of Propiconazole @ 0.10% (first at tillering and second after 15 days) in minimizing the spot blotch severity with highest seed quality traits. This treatment also resulted in 40.64 per cent yield increase as compared to untreated and water sprayed plot.

CONSERVATION AGRICULTURE: MITIGATION AND ADAPTION OF CLIMATE CHANGE

MOHAMMAD HASANAIN¹, D.K. SHUKLA,² V.K.SINGH,¹ RAJIV K. SINGH¹ AND PRAVEEN K. UPADHYAY¹

¹ICAR-Indian Agriculture Research Institute, New Delhi, 110012, ²Govind Ballabh Pant University of Agriculture & Technology, Pantnagar, Uttarakhand, 263 145

Ever increasing global population, particularly in many developing countries requires increased supply of food, fibre, oil, which poses a grave challenges before the agriculture scientists to produce more and more from limited, shrinking and degraded land and water resources. Tilling soils continuously without adding organic matter has adverse effects on soil health and quality of the produce. Conservation agriculture (CA) is the integrated management of the available natural resources such as soil, water, flora, and fauna with partial outside inputs which increases the efficiency of natural resource use. It provides sustainability in farming production through maintaining the quality of natural resources by stable or semi-stable organic cover to soil. Zero or minimum tillage or no-till (NT) and minimum disturbance of soil along with varying rotation of crops are a must for future prospects. CA is an integrated approach to agriculture cultivation that helps enhance food security, allay poverty, conserve biological diversity, and preserve ecosystem services. CA practices are also helpful in making farming systems more resilient to recent climatic changes. CA can comprise wide-ranging practices such as management of forage and farm animals, fallows improvement, combined cultivation of agricultural crops and trees as agroforestry, management of watershed, and management of areas which are reserved for village and community people. Then the potential of CA as a source to alleviate and acclimatize to climate change will be examined for climatically affected environment (FAO 2011). CA is the best management of natural resources like soil, water, vegetation, and biodiversity for sustaining the future prospects. CA have potential to decrease the effects of changing climate by optimizing crop productivity and advantages while maintaining a coordination among agricultural, monetary, and ecological benefits (FAO 2011a ; Giller *et al.* 2009). The CA practices can also add to making farming systems more flexible to climate change. In several cases, CA has been demonstrated to reduce agricultural systems' green-house gas (GHG) emissions and increase their job as carbon sequestration. As an estimate, nearly 1.5 MT plant nutrient are being lost due to burning annually (Jain *et al.* 2014). Residue burning also kills the beneficial microorganisms present in the soil required for different biological processes. Release of different greenhouse gases leads to increase in atmospheric CO₂ which is the ultimate cause of the changing climate (Chivenge *et al.* 2007). The CAPs is a powerful mechanism to adapt to climate change by increasing resilience to drought and increasing water and nutrients use efficiencies (WUE and NUE). Climate change is believed to have a great impact on soils. Increasing temperature would increase oxidation of the organic carbon in soil. Its levels will go down further. Incidence of runoff or wind erosion may increase due to increase in extreme events. These changes may reflect themselves in poorer soil fertility, loss of soil biota, water stress, and groundwater depletion (FAO2011a, b). The ecological benefits from CA are operationally defined as "increase in soil fertility," "retention of soil moisture," "long-term yield increase," "decreasing yield variations," "greater food security," "increased growing time of an area," and "production per hectare" (Pittelkow *et al.* 2015).

SCREENING OF SELECTED SPINACH CULTIVARS FOR THEIR RESPONSE TO THE ROOT-KNOT NEMATODE, *MELOIDOGYNE INCOGNITA*.

MOHAMMAD SHARIQ*, MOHD. ASIF, AMIR KHAN, FARYAD KHAN, MOH. TARIQ, TARUBA ANSARI AND MANSOORA. SIDDIQUI

Section of Plant Pathology and Nematology, Department of Botany, Aligarh Muslim University, Aligarh, India.

The Root-knot nematode, (*Meloidogyne incognita*) is the most damaging pathogens of vegetables, especially in the tropical and

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

subtropical regions. Increasing restrictions of chemical nematicides have given rise to growing attention and interest in alternative nematodes management. Among the non-chemical methods available to nematodes control, the use of resistant cultivars can be one of the most effective and environmentally safe alternatives over chemical control. An investigation was carried out to assess the level of resistance in five selected spinach cultivars viz., All green, Green Flavour, Kantedar, Pure green and Super green against *M. Incognita* under greenhouse condition. The nematode development and host damage were evaluated by recording the nematode infestation parameters and percent reduction of plant growth. All the tested cultivars varied significantly in causing reductions in growth parameters over their controls. Similarly, all the cultivars behaved differently regarding the formation of galls and egg masses and the nematode development. It was observed that none of the tested cultivars was immune or highly resistant. The cultivar Kantedar was found moderately resistant against *M. Incognita* as it showed minimum root gall index and reduction in growth parameters while cultivar All green was found highly susceptible showing the highest root-knot index and reduction in growth parameters. Similarly, the cultivar Green flavour and Pure green were susceptible; the cultivar Super green was moderately susceptible against the nematode damage. A significantly negative correlation was found between the number of galls and plant growth parameters.

Keywords: *Meloidogyne incognita*, Screening, Spinach, Resistance.

ORGANIC FARMING: EFFECTS ON CROP PRODUCTIVITY, FOOD QUALITY AND ENVIRONMENT

¹MOHD ABBAS, ²AHMAD ALI AND ³MOHIT HUSAIN

¹Division of Floriculture, ²College of Agricultural Engineering and Technology, ³Faculty of Forestry, Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir-190025, India.

The green revolution has increased the food grain production of our country to a state of sufficiency due to use of high yielding varieties, fertilizers, pesticides and other inorganic inputs. But this intensive cultivation has not only led to pollution of soil, water bodies, underground water and the environment but also affected the human beings. Further with increased demographic pressure and shrinking resource base due to enhanced industrialization and urbanization, it seems difficult to feed the future population in a sustainable manner with environmental protection. So, there is a need to go for a truly sustainable farming system on a wide scale to meet this challenge and ensure food and ecosystem security. A system is called sustainable only if it gives sufficient amount of quality food, increases the natural resource base, protects the environment, is economically viable and contributes to the wellbeing of farmers and their community. In this regard, organic farming seems to be the better alternative to conventional farming. Organic farming is a production system that promotes environmentally, socially and economically sound production of food and fibres and excludes the use of synthetically compounded fertilizers, pesticides, growth regulators, livestock feed additives and genetically modified organisms. The overall goal of organic farming is to provide food of high quality with minimum environmental impacts in a sustainable manner. It is often called as organic agriculture, ecological or biological agriculture. Many researchers believe that organic farming is ideologically driven and inefficient, and in comparison to conventional farming, it requires more area to produce the same amount of food as conventional agriculture.

Keywords: Green revolution, sustainable farming, organic farming, productivity.

SOIL MOISTURE CONSERVATION TECHNIQUES

MOHD. MUED¹, MUBEEN², VISHAL KUMAR³, SALMAN AHMAD¹, FARIA FATIMA¹, SUNEEL KUMAR¹ AND NADEEM KHAN¹

¹Department of Agriculture, Integral Institute of Agricultural Sciences & Technology, Integral University, Lucknow-226026, UP, India,

²Faculty of Agriculture Sciences, Mohammad Ali Jauhar University, Rampur- 244901, Uttar Pradesh India, ³Department of Agronomy, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi 221005, UP, India

Soil Moisture is a key factor that impacts on the productivity of the soil. Soil moisture losses affects on the metabolic function of crops and crop production as well as population and activities of soil microorganism. Therefore, importance of soil moisture conservation much more needs especially in dry land areas as well as there where irrigation facilities very difficult. Three main factors affect soil moisture content: (a) How well the soil can absorb water; (b) How well the soil can store moisture; and (c) How quickly the water is lost or used. These factors controls used by following techniques: (1) Cover the soil after sowing and harvesting of crops by the crop residues left, (2) Deep and opposite of slope ploughing of soil in the summer season before onset of monsoon, (3) Made bunds around field in monsoon season, (4) Uses of contour farming practices in the hilly areas, (5) Organic resources and fertilizers apply in the field, (5) Minimized losses of moisture by the different type natural and artificial mulches involved in the cultivation of crops, (6) Used different type of anti-transpirant chemicals on the crops for mitigate the process of transpiration, (7) Intercropping and mixed cropping of farming techniques to minimize soil moisture losses by the evaporation, (8) Crop rotation practices involve in cultivation because deep rooted and shallow rooted crops that make use of previous unused soil moisture, as plants draw water from different depth level within the soil (9) green manuring such as growing of leguminous crops with the sole, purpose of adding to the soil for improved organic matter and improves water retention capacity.

Key words: Soil moisture, moisture conservation technique, ploughing, mulches and green manure.

WATER MANAGEMENT IN SMART AGRICULTURE**¹MOHD. SALIM MIR, ¹UMMAISA REHMAN ²ZAKIR AMIN, ²SHIFASHOWKET, ³ASHAQ AHMAD,***¹Division of Agronomy, SKUAST, Kashmir; ² Division of Plant Pathology, SKUAST, Kashmir; ³ Division of Soil science and Agricultural Chemistry, SKUAST, Kashmir*

Due to irregularity of rainfall and decreasing water level, it has become very necessary now that due to the intervention of water management, the excess consumption of water consumed in agriculture should be fulfilled in such a way that only the small amount of water in the tab to get the full water of their needs, first we have to collect rain water. Use the water on the collection as follows: Use water to reduce the amount of water used Waste so that we can use the rest of the water in other works. Interventions in water management Smart Agriculture: Interference with natural water (1) Land collation by laser: The technique of colloquialization by laser is a new technology in which the role of tractor driver is zero, the action of collagenation is done by laser itself. Studies have shown that 10% of the paddy fields coated in laser and 10 in the field of wheat 20 percent water can be saved. (2) Use of crop change or drip: The profitability of the paddy wheat crop cycle is decreasing day by day, along with the cultivation of vegetables and fruits, if drip irrigation is also provided, then more water can be saved, one big benefit of drip irrigation it is also possible that underground saline water found in dry or semi-arid areas can be used. (3) Groundwater recharge: Excessive emphasis should be given on the use of ground water recharge rather than draining the water into the drains, the following measures can be taken. Excavation and renewal of old ponds: Recharged on the roof by cultivating water or roof water, Use of surface and underground drainage, Construction of potholes on the banks of fields and construction of pits for water harvesting on the shore.

Keywords: Irregular rainfall, Ground water recharge, water harvesting

ADAPTABILITY PERFORMANCE OF VARIOUS EXOTIC POTATO VARIETIES AT HIGH ALTITUDE RESEARCH STATIONS OF GILGIT BALTISTAN**MUHAMMAD SHAH ZAMAN, FAZAL RAHMAN, SHAKIRULLAH, MUHAMMAD KHALID AND ZULFIQAR AHMAD**

Directorate of Agriculture Research Gilgit Baltistan, GB A trial of nine potato varieties (Bartina, Sante, Pameela, Melanto, Lady Rosetta, Roko, Asterix, Koruda and Zena Red) was conducted at two different locations of Gilgit Baltistan (GB) at Horticulture Research Station Yaseen Ghizer and Agriculture Extension Farm Phandar at an altitude of above 7000 feet from the sea level. Potato and vegetable Research Station Naltar Gilgit and Potato Research Station Babusar. A same lay out plan was used in both Research stations where raised ridges were prepared with 5 m length having plant into plant distance (15 cm) whereas the row into row distance was kept at 75 cm. Initial dose of Nitrophos @ 25 kg/kanal was applied during sowing time of seed potato and Urea @ 10 kg/kanal was applied at three different stages. The whole experiment was replicated three times and the data was collected and analyzed using Completely Randomized Block Design (RCDB). In our study the var. Roko, Lady Rosita and Bartina showed 100% germination at Yaseen followed by Melanto, Asterix and Sante (99%) while, the least germination rate was recorded in the var. Zena Red in three locations (Yaseen and Phandar). The varieties with high germination rate would be selected to proliferate in the area during the current potato growing season. Maximum plant height was recorded in Pameela in all locations with highest plant height in Yaseen region (100.3 cm). Maximum number of stems (05) was recorded in Bartina at Naltar followed by Lady Rosita (4.4) and Roko (4) stems plant-1. Minimum (1.4 and 1.8) number of stems plant-1 was noted in Zena Red in Yaseen. Similarly the maximum (12.8) number of tubers plant-1 was recorded in Melanto followed by Lady Rosita at the same location of Yaseen. Our experiment depicted highest yield by Roko that produced 30.9 mt/ha at Yaseen. The var. Sante and Zena Red emerged as the least adaptive potato variety with 12.0 mt/ha and 8.9 mt/ha at same locality of Yaseen respectively. On basis of the field adaptability test the high yielding and most suitable varieties of Potato will be grown in the research stations / farms and further be proliferated to boost the seed potato industry in the area through progressive farmers in collaboration of Agriculture Extension Department of Gilgit Baltistan.

Key word: Potato, Solanum, tuberosum, Seed Potato, adaptability, yield.

ASSOCIATION STUDIES IN MAIZE (*ZEAMAYS L.*)**MOHIT & B. R. KAMBOJ***Department of Agronomy, CCS Haryana Agricultural University, Hisar-125004*

Maize (*Zea mays L.*) is a cereal crop of global importance, belonging to the grass family *Poaceae*. It is the third most important cereal crop in the world after rice and wheat. As it has yield potential far higher than any other cereal, it is also referred as the '*Miracle crop*' or the '*Queen of Cereals*'. The consumption pattern for maize produced in India at present includes poultry feed, human food, animal feed, starch, brewery and seed. The present investigation was carried out at Research area of Regional Research Station, Karnal, Chaudhary Charan Singh Haryana Agricultural University, Hisar during *Kharif* season to estimate the magnitude of comparative performance of different methods of establishment on yield. Positive and significant correlations of grain yield, cob length, diameter and 100- grain weight was found in hand dibbling as compared to sowing with zero till drill machine.

Key Words: Maize, Zero till, Association, Yield

OPTIMIZATION OF DYEING PROCESS OF ONION SKIN DYE FOR BIOPOLYMER TREATED COTTON FABRIC

MONA VERMA¹, SAROJ S. JEET SINGH² AND NEELAM M ROSE³

Ph.D Scholar¹, Professor² and Professor³, Deptt. of Textile and Apparel Designing, I. C. college of Home Science, Chaudhary Charan Singh Haryana Agricultural University, Hisar

Textile dyeing and printing industry is one of the most polluting sectors from an ecological point of view. There is need to approach new strategies, methods, material for dyeing treatment of cotton fabric with natural dyes using environment benign route. To achieve the objectives of the study, different biopolymer and natural dyes were tried and one was selected on the basis of colour properties of dyed fabrics. Standardization of chitosan treatment and dyeing process for selected onion skin dye was done on the basis of colour properties i.e. dye absorption colour strength and wash fastness for different concentrations and conditions. It was found that the chitosan treated onion skin dyed fabric showed higher dye absorption (66.17%), colour strength (16.52), wash fastness rating than alum treated dyed fabric (55.98%, 12.21 k/s, 4/5) respectively. Thus it is concluded that chitosan treatment enhanced colour properties without using any harsh chemicals and is capable enough to replace the use of salts and alkali in dyeing with natural and synthetic dye. The chitosan treatment along with onion skin dye imparted the multi-functionality to the cotton fabric in terms excellent protection against UV radiations, antibacterial and crease resistant properties effectively with environmental friendly manner, reduced the pollution load on environment and save resources.

Key Words: Chitosan, Onion Skin, Natural Dyes, Cotton

DOUBLING FARMER'S INCOME: AN INITIATIVE TO EMPOWER FARMERS IN INDIA

MONU KUMAR JHA* PROF. CHANDRASEN, RAVI SHANKAR GIRI, NAVNEET KUMAR SINGH AND VIRENDRA KAMALVANSI.

Department of Agricultural Economics, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi 221005, India.

Sustainable Development Goals (SDGs) are a plan and also one roadmap for alleviating poverty and improving the living condition of the local community. More than 53 per cent Indian people are engaged in Agriculture as the main occupation. A new and innovative agricultural productivity enhancement of technologies and capacity building of Agriculture farmers provide a natural push for SDGs. The Government of India has set up the panel of doubling Farmer's Income by the year 2022. The Government has initiated various agricultural reforms such as enhancing productivity, improving profitability, encouraging organic farming and many other efforts. Doubling farmer's income is a very big task as farmers are facing many problems like climate change, soil degradation and lowering of water level etc. Agriculture plays an important role in Nation's economy in India. India's 54.6 percent of the population is engaged in agriculture and allied activities (census, 2011). According to FAO, by 2042, the world will have nine thousand million hungry people to feed, India alone accounting for 1650 million of those. As per the provisional estimates released by the Central Statistical Office (CSO) on 31st May 2016, the agriculture and allied sector contributed approximately 17 percent of India's Gross Value (GVA) at current prices during 2015-16. If we want to remove the problem of malnutrition in India, we need to increase food production by 80 percent. To overcome the farming related problems, enhancing Agricultural productivity and improving farmers' income is a big challenge. For this, we have to analyze how they are doing farming and what more can be done to improve their farming ways and agriculturally related income through knowledge interventions and training. Agriculture plays a pivotal role in SDGs, like food security, overcoming the problems of hunger and poverty alleviation is closely linked to it. Total 78 percent of the world's population is dependent on agriculture not only for their food but also for their livelihood and Agricultural Development.

Keywords: Agriculture, Development, Farmer's income, and Livelihood.

DEVELOPMENT OF SUITABLE PACKAGE FOR MANAGEMENT OF LATE BLIGHT OF POTATO AND ITS IMPACT ON CROP GROWTH AND YIELD

MORAJDHWAJ SINGH* S. K. BISWAS¹, RAMJI SINGH AND DEVESH NAGAR²

Department of Plant Pathology, Sardar Vallabhbhai Patel University of Agriculture & Technology, Modipuram Meerut, 250110 India,

^{1&2} Chandra Shekhar Azad University of Agriculture & Technology, Kanpur- 208002 (U.P.) India

Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious diseases of potato. Several management practices have been adopted so far to minimize the disease. But in present investigation based on laboratory and glass house condition revealed that tuber seed dressing with bio-fertilizer provided good protection against late blight and also stimulate the germination. The data showed that the plant height of potato was maximum in treatment T₇ (soil application of mustard cake + tuber treatment and foliar spray with *T. viride*) with the value of 11.16cm at 30 day age of plant. Growth promoting effects of the bio-fertilizer were also perceived. The bio-fertilizers were found to increase the plant length over control. Foliar spray with the bio-fertilizers after pathogenic inoculation protected the plants against infection resulting reduced disease severity. The minimum disease severity (7.82%)

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

was reported from *treatment where treatments were given as treatment T₇* (soil application of mustard cake + tuber treatment and foliar spray with *T. viride*) treated plants against 96.0% disease severity in case of control. Plant treated with bio-fertilizers after the challenge inoculation sensitized the plants to produce increased levels of soluble protein. The maximum increase in protein content was found in treatment T₇ (Soil application FYM @150gm/pot + mustard cake @ 150gm/pot + tuber treatment with *T. viride* + foliar spray with bio-formulation of *T. viride*) after 15 days of pathogenic inoculation. A high content of phenol was also recorded in treated leaves which were maximum in treatment T₆ (Soil application FYM @150gm/pot + tuber treatment with *T. harzianum* + foliar spray with bio-formulation of *T. harzianum*). The correlation coefficient between disease severity with total soluble protein and total phenol content showed negative correlation in both the cases.

ECO FRIENDLY MANAGEMENT OF DISEASES AND PESTS IN SEED SPICES THROUGH PLANT PRODUCT MSANNU¹, MOHIT KUMAR²

Department of Extension Education and Department of Plant Pathology, College of Agriculture, Swami Keshwanand Rajasthan Agricultural University, Bikaner

The productivity of most of the seed spices is considerably low in Rajasthan due to various infestation by plant diseases and pests is major factor. Several seed spices of pathogens, insects, mites and nematodes attack these crops in the field and during storage. Several plants extracts, synthetic, microbial compounds and organic pesticides have been used extensively to reduce yield loss and increase crop profitability without chemical residues in the produce. Chemical control produce harmful side effects on beneficial organisms, mortality of pollinators, environmental pollution. Since seed spices are high value and export oriented commodities, levels of pesticide residues are to kept well below tolerance limits in view of the stringent standards set by the importing countries thus the growing concern over pesticide misuse has led to the development of IPM schedules for sustainable management of pests and diseases in recent years. Plant products form an important component in the development for IPM schedules. Among indigenous plant species like neem, garlic, ginger and onion have been extensively studied for bio-active constituents in different plants parts. Farmers use local traditional preparations such as neem seed kernal extract, neem leaf extracts, neem oil, neem cake for the management of various diseases and pests. These plant extracts have great potential for ecofriendly management of diseases and insect pests of seed spices crops. These products act as antifungal and antibacterial against different diseases causing pathogens and also inhibitor of sporulation, development of hyphae of fungal pathogens. antifeedant, growth regulator, repellent action against various pests of seed spices crops. These above mentions characteristics in plant extracts that help to reduce the diseases and pest infestation without create any health hazardous and residues effects and also eco-friendly for environmental view

HORTICULTURE INNOVATIONS AND ENVIRONMENT CONSERVATION MUDASIR IQBAL, MOHSIN IQBAL AND ***NAVEED HAMID

*Division of Fruit Science, Division of Plant Pathology, Faculty of Agriculture, Main Campus, Chatha, ***Ministry of Agricultural Cooperation and Farmer's Welfare, New Delhi, Sher-e-Kashmir University of Agricultural Sciences & Technology of Jammu, J&K-180009, India, Key Words: Horticulture, Environment, Management, Conservation, Mitigation*

Horticultural production basically involves the intensive use of natural and artificial resources, such as land, water, labour and inputs such as fertilisers, pesticides and horticultural implements. The use of these resources in a temporal basis has the potential to negatively impact on the local environment and worker welfare. In addition the transport of horticultural produce over long distances, particularly by air transport, and reported in term of food miles, is known to have a negative contribution to the global environment. The use of technologies that have been used to mitigate the impact of horticultural production on the environment are highlighted including greenhouse technologies, soil protection and conservation, optimal fertiliser use and Integrated Pest Management. The past decade has seen an increasing awareness of man's activities on the planet's environment. The horticultural value chain has affected virtually every aspect of the environment. In addition we have seen greater advances in quantifying the impact of horticultural activity on the environment. By understanding and measuring, then scientists and growers themselves have been able ways to minimise their effect on the environment through the use of technology and management strategies. This is likely to be an on-going scenario. Climate change and variability will affect horticulture system substantially, requiring orchardists to adapt at the same time that they are called on to reduce emissions at the orchard level. Choosing effective adaptation and mitigation strategies will represent a key challenge for farmers over the coming decades. However the climate change we are seeing currently is as a result of practices totally outside horticulture and in future global warming and the environmental impact on horticultural production may be more important than horticulture's impact on the environment.

OPTIMIZING DRIP IRRIGATION SYSTEM DESIGN FOR ONION CROP USING DIDAS SOFTWARE**MUKESH KUMAR MEHLA¹, KHYATI SINGH²**¹Department of Soil And Water Engineering, COAE&T, CCS Haryana Agricultural University, Hisar- 125004, ²Department of Vegetable Science, Maharana Partap Horticultural University, Karnal- 132001, *Corresponding author- Mukesh Kumar Mehla

Water is a key limiting factor in crop production. Use of drip irrigation system for growing vegetable crops can help in sustainable use of water. In close growing crops like onion which has shallow root zone depth (i.e. 8 inches) designing drip irrigation system which will cover the crop water requirements effectively becomes important. DIDAS software is used in design of drip irrigation systems and irrigation scheduling of various annual crops and trees at various soils and evaporation conditions. DIDAS's drip system design tool can be used for optimizing design of drip irrigation system which is based on steady irrigation and water uptake processes to study the effect of geometrical attributes on water use efficiency. Geometrical attributes includes distances between emitters along driplines and between driplines, the depth of emitters for subsurface systems and the size and depth of root systems. It performs computations based on analytical solutions of the relevant linearized water flow and uptake problems. Design tool is based water uptake rate criterion (RWUR, ratio between water uptake rate and irrigation rate) assuming no plant-atmosphere resistance to water uptake based on three input parameters describing the soil texture, the size of the root zone and the potential evaporation. The design tool compute the RWUR and its output is the RWUR as a function of the radius of the root zone(r_r) for different emitter or dripline spacings, depending on the chosen scenario. The program was run for different spacings, it evaluated relative water uptake rate (RWUR) as a function of root zone radius (r_0), and best spacing was selected based on results.

Keywords: Irrigation management, Trickle irrigation, Water use efficiency, Drip irrigation,

ROLE OF SALINITY STRESS ON PHYSIOLOGICAL, BIOCHEMICAL AND YIELD CHARACTERS OF MUNG BEAN *VIGNARADIATA*(L.)**MUKUL KUMAR¹ & UMAKANT SINGH²**

Deptt. of Botany & Plant physiology, M.B.A.C. Agwanpur, Saharsa (B.A.U., Sabour. Bhagalpur, Bihar), Horticulture (Vegetable Science) Department of Horticulture, Regional Research Station, Agwanpur, Saharsa, B.A.U., Sabour. Bhagalpur (Bihar)

Mung beans were first domesticated in India, where they grew as wild plants. Archaeological evidence shows that mung beans were growing in the Harappan civilization. The present study was aimed at evaluating salinity stress tolerance status of the recently released variety. Physiological parameters like membrane injury of leaves and roots, and leaf succulence increased with salinity stress, while converse was true for chlorophyll fluorescence, relative water content, aerial biomass and harvest index. Soluble sugars, amino acids and proline content of fully expanded leaves increased significantly, while protein and starch content decreased with the increasing level of salinity. Number of flowers per plant, stamen length, number of pollen per flower, pollen size and their fecundity, pistil length and number of ovules also decreased with salinity, while the values for percent fertilized ovules remained unchanged. Similar to decline in starch, protein and guar gum content of seeds, seed yield and number of pods per plant also decreased with salinity, thereby indicating deterioration of seed quality.

Keywords--Salinity, Stress, Reproduction, Pollen, Yield, mung bean.

TOLERANCE AND BIOACCUMULATION OF HEAVY METALS (CD AND PB) BY ENDOPHYTIC FUNGI**N.P. NAVNAGE¹*, ASIT MANDAL², VINAY SAMADHIYA¹, J.K. THAKUR², A. SINGH², M.C. MANNA², ASHOK K. PATRA²**¹Department of Soil Science and Agricultural Chemistry, Indira Gandhi Krishi Vishwavidyalaya, Raipur 492012 C.G., ²Division of Soil Biology, ICAR-Indian institute of soil science, Bhopal 462038, MP*

Global modernization, industrialization, urbanization have resulted in increased contamination of our environment by heavy metals. A long persistence of heavy metals in nature has in turn resulted in development of metal resistance microbial strain. Microorganism plays a significant role in bioremediation of heavy metal contaminated soil. In this study, an attempt was, therefore made to test a strain of *Penicillium* Sp. (EN1) isolated from root of *Amaranthus spinosus* spices were collected from contaminated site of Bhanpur Bhopal (MP) has been studied for tolerance to heavy metal (Cd and Pb) and for its capacities to uptake heavy metals. Endophytic fungi were isolated and identified as *Penicillium* sps by morphological and biochemical study. It was found that endophytic fungi capable of surviving on media containing graded level of heavy metal concentration of cadmium and lead. Tolerance ability of fungus to heavy metal was determined by culturing on potato dextrose agar at concentration ranging from 0-20 ppm. The tolerant growth were studied for removal of heavy metal with respect to Cd and Pb which showed the maximum uptake of lead (Pb) of 85.7% and least uptake of cadmium (Cd) of 39.1% at increasing concentration (0-20ppm). This indicated that potential of these endophytic fungi as bioaccumulation of heavy metal from contaminated site containing higher concentration of heavy metals which make them attractive potential candidate for bioremediation agent. The result of this study could provide a basis for exploring the role endophytic fungi for an environmentally friendly and economically feasible decontamination of heavy metal. Finally the result indicated that *Penicillium* could be a prospective candidate to increase the phytoremediation efficiency of plant and play important role in decontamination of pollutant area.

Keywords: Heavy metal, tolerance, bioaccumulation, endophytic fungi, soil contamination

FIELD AND LABORATORY LIFE TABLE OF OKRA SHOOT AND FRUIT BORER (*Earias vittella* FABRICIUS) ON OKRA

N. S. RODE^{1*}, M. F. ACHARYA² AND P. S. WADASKAR²

MGM, NK College of Agriculture, Aurangabad (MH), Junagadh Agricultural University, Junagadh (GJ)

Investigations on life table of *Earias vittella* (FABRICIUS) on okra was carried out at Sagdividi Farm of Junagadh Agricultural University, Junagadh. Field life table indicated that egg stage of contributed 20 per cent mortality mainly due to egg sterility. Key mortality factors operating under field conditions for mortality in younger and older larval group was viral, bacterial and fungal infections and *Cotesia* sp. The value of generation survival and trend index was found 0.44811 and 0.0166, respectively. In immature stages the maximum mortality was recorded during pupal stage while, lest mortality was observed in the older larval group. The age specific life table showed that the survival of *E. vittella* up to 35 days whereas, age specific survivorship decreased from 1 to 5 day. Life expectancy was high in the beginning of the age and remained the same with slight fluctuation up to 13 day. The stage specific life table indicated that maximum values of apparent mortality, mortality survival ratio and indispensable mortality were observed in pupal stage. Whereas, the highest survival fraction was recorded at 4th instar stage. Pupal stage exhibited highest K's value whereas minimum was observed at 4th instar stage. The mean length of generation was 33.01 days with potential fecundity 136.35 eggs per female. Net reproductive rate 68.214, hypothetical F2 female 4653.18 females/ female and intrinsic rate of increase 0.1479 females/ female/ day, finite rate of increase 1.14 and annual rate of increase 2.34×10^{20} were recorded.

PERFORMANCE OF DIFFERENT GENOTYPES OF GAILLARDIA (*GAILLARDIA PULCHELLA* L.) IN RESPECT OF YIELD AND QUALITY ATTRIBUTES

NAGESH GAWADE¹, BHALEKAR S. G.², VAIBHAV WADEKAR³, PUSHPANJALI BHOSALE⁴ AND UTSAV DEVDHARA⁵

^{1&5} Junagadh Agricultural University, Junagadh-362001, ^{2,3&4} College of Agriculture, Pune-05, MPKV, Rahuri

The present investigation was carried out during the year 2015-2016 at Modibaug garden of Horticulture Section, College of Agriculture, Pune. Significantly more number of flowers per plant was recorded in the genotype MG-2-2 (288.35) followed by the genotypes MG-7-1 (263.23) and MG-9-1 (242.43). The genotypes MG-9-1 and MG-7-2 recorded significantly maximum weight of 100 flowers (333 g). The weight of flowers per plant, yield of flowers per plot and yield of flowers per hectare were recorded significantly highest in MG-9-1 (631.00 g, 12.02 kg and 33.30 tonne) respectively. The Aureolin flower colour was observed in two genotypes viz., MG-4-3 and MG-7-3 two genotypes. The Lemon Yellow flower colour was observed in twelve genotypes viz., MG-3-1, MG-5-1, MG-5-3, MG-6-2, MG-8-1, MG-9-2, MG-10-1, MG-10-3, MG-10-5, MG-12-2, MG13-1 and MG-14-1 genotypes. The Buttercup Yellow flower colour was observed in twelve genotypes viz., MG-1-3, MG-1-4, MG-2-2, MG-3-2, MG-3-4, MG-4-2, MG-4-4, MG-5-4, MG-7-2, MG-8-2, MG-9-4 and MG-12-1 genotypes. The Indian Yellow flower colour was observed in fourteen genotypes viz., MG-2-1, MG-3-3, MG-4-1, MG-5-2, MG-5-5, MG-6-1, MG-7-1, MG-9-1, MG-9-3, MG-10-2, MG-10-4, MG-11-1, MG-12-3 and the Local check. The shape of petals of genotype MG-4-2, MG-5-3, MG-6-2, MG-7-2, MG-10-1 and MG-10-5 of gaillardia had narrow with blunt tip and remaining genotypes had shown narrow with pointed tip. The genotype MG-6-1 and MG-14-1 had dense pubescence. The genotypes MG-2-1, MG-3-1, MG-5-4, MG-7-1 and MG-10-2 had medium pubescence. The remaining 33 genotypes had comparatively low pubescence.

Key words: Gaillardia genotypes yield and quality attributes.

HEALTH ENHANCING PROPERTIES OF ORNAMENTAL EDIBLE FLOWERS

¹NAIKWAD DHARMENDRA, ²UMESH AND ³ANURADHA BHAGAVATI

¹Department of horticulture Assam Agricultural University, Jorhat-13, ²Kerala Agricultural University, Thrissur-680656, ³University of Agricultural Sciences, Raichur-584101

On a global scale people are demanding for more attractive, tasty and healthy foods. Both quality and aesthetic aspects contribute to the acceptance of foodstuffs. Ornamental edible flowers with high pigment are found to enhance the aesthetic as well as the nutritional value of food. The ornamental edible flowers those which are non poisonous and does not cause any negative reaction in body or in other words edible flowers are those which contains alkaloids showing pharmacological activity. Edible flowers are abundant natural resources found worldwide and most of them contain numerous phytochemicals with health benefits which has attracted more and more attention. The edible flower contains major phytochemicals such as carotenoids, phenolics, alkaloids, nitrogen-containing compounds, and organosulfur compounds. These phytochemicals makes edible flowers as anti-free radical, antitumor and anti-inflammatory and antimicrobial functional foods. The most part of the antioxidants in the edible flowers are pigments such as anthocyanins and carotenoids often present in high concentration. Edible flowers are playing the role of nutrition as they are rich source of nutrients like carbohydrates, proteins, vitamins, minerals, fatty acids, dietary fibres and organic acids. Common edible flowers like *Nelumbo nucifera* (lotus), *Borago officinalis* (borage), *Rosa* spp. (rose), *Crocus sativas* (saffron) and *Taraxacum officinale* (dandelion) for their nutrient content, their

disease curing properties and other uses. Edible flowers are also an excellent source of minerals, especially of phosphorus and potassium. The consumption of crops rich in potassium is recommended for the prevention of cardiovascular or oncogenic diseases. Polyphenols are common constituents of the human diet, present in most foods and plant materials. They are known to contribute to the prevention of various diseases, including cancer, neurodegenerative diseases, osteoporosis and cardiovascular diseases. Many of the ornamental edible flowers were traditionally used to cure diseases. The growing interest in nutraceuticals and functional foods will increase the new foods production are beneficial to health. Exploration of indigenous ornamental edible flowers which may ultimately boost the acceptability of these flowers for health protection also as well as promotion.

INTEGRATED WEED MANAGEMENT IN SUGARCANE**NAKKASOWMYA¹ JNANABHARATI PALAI²***M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, Dept. of Agronomy, M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha*

Sugarcane (*Saccharum officinarum* L.) is an important cash crop occupies an important position in Indian agriculture. Sugar industry is the second largest agro based industry after textile industry located in rural areas in India. Sugarcane is a long duration crop which takes longer time for germination due to which crop faces tough competition with weeds between 60 to 120 days of its planting which causes heavy reduction in cane yield ranging from 40-67%.. This low productivity is mainly due to heavy weed infestation. Widely spaced crop of sugarcane allows wide range of weed flora to grow profusely in the interspaces between the rows. Frequent irrigations and fertilizer application during early growth phases increase the weeds menace by many folds in the crop. There are several weeds infesting sugarcane fields in India, the predominant among them are *Cyconodon doctylon*, *Cyperus rotundus*, *Echinochloa* spp, *Saccharum* sp among narrow leaved and *Chenopodium album*, *Solanum nigrum*, *Convolvulus aremins* *Trianthema* sp. *Digera arvensis*, *Anagallis arvensis*, *Fumaria* sp. etc. among broad leaved weeds. The intensity of these weeds depends on agro-climatic condition of the region. Research results indicate that more crop-weed competition occurs during early phase of sugarcane growth. Therefore Integrated Weed Management (IWM) is holistic approach to control weeds in sugarcane and enhances the yield.

Keywords: IWM, weeds and productivity.

COMBINING ABILITY STUDIES IN AMERICAN COTTON**(GOSSYPIMUM HIRSUTUM L.)***Nalanda A. P*, Patil B. R., Deshmukh S. B. and Bainade P. B., Department of Agricultural Botany, Post Graduate Institute, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola 444104 (M.S.), (RESEARCH PAPER IN AGRICULTURAL BOTANY)*

The Present investigation was carried out to estimate the combining ability effects for various characters in cotton to find out superior cross combinations. Line x Tester model was selected for to study. The 4 females (lines) viz., AK-32, AK-023, AK-053, AK-8660 and 3 males (Testers) viz., AK-780, AK-976 and AK-3614-10 and their 12 crosses were evaluated in Randomized Block Design at the research field of Cotton Research Unit, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola, during *kharif* season of 2013. The mean sum of squares due to genotypes were highly significant for all the traits. This indicated the substantial genetic variability among the all genotypes. Among the female parents, parent AK-053 had recorded the highest gca effects for seed cotton yield per plant, boll weight and oil content. From the male parents, parent AK-780 recorded the highest positive gca effects for seed cotton yield per plant and parent AK-976 recorded significant gca effects for days to 50% flowering, seed index, oil content, 2.5% span length and fibre fineness. The cross AK-32 X AK-780 (5.639) recorded highest positive sca effects for seed cotton yield per plant and the cross AK-023 X AK-780 (1.747) recorded significant positive sca effects for 2.5% span length. The cross AK-053 X AK-780 revealed positive sca effect for seed cotton yield per plant and both the parents involved revealed high gca effect for seed cotton yield. Hence, this cross should be tested over locations and years to get clear cut idea regarding its performance.

Key words: Cotton, Line x Tester, General combining ability, Specific combining ability.

LAND USE PLANNING AND THEIR MANAGEMENT**¹NARENDRA KUMAR BHARATI ²SURESH KUMAR SABAL***Department of Soil Science and Agriculture Chemistry, College of Agriculture, MPKV, Dhule- 424004 (M.H.), Department of Entomology, College of Agriculture, SKRAU, Bikaner- 334006 (Raj.)*

Land use planning is a science that determines the type of land use through studying the ecological character of the land as well as its socio-economic structure. It is possible to plan for the appropriate use of the land and to enhance the present management of the land use by utilizing Geographical Information System (GIS). Land-use planning is established based on national economic and social development the demand for land as well as areas of natural, economic and social conditions. It is the leading of the entire land management in their daily planning and management because the outcome of data and file data types are more the number of large follow the conventional manual approach to management and applications can no longer meet the current economic development of the land management needs. It provided the conditions for the establishment of management information systems because of the GIS technologies. Land-use planning and management information system is based on land-use planning for the center, including a number of land-use business management and office automation integrated, space-based information systems. Digital maps were inputted along with explanatory data into an ArcGIS software application. In addition, all digital maps of layers including, elevation, slopes and aspects, soil texture, depth and structure, geology, iso-hyetal, iso-thermal, iso-evaporation, soil erosion, vegetation or canopy percentage, climate and water resources have been integrated- superimposed in the ArcGIS environment

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

based on the Makhdoom analytical and systematic analysis model.

RECENT ADVANCES IN POLLINATION MANAGEMENT IN FRUIT CROPS

NARENDRASINGH¹, SAGAR², SANDEEPMATHUR³

¹*Division of Fruits and Horticultural Technology, ICAR- IARI, Pusa, New Delhi, India,* ²*Department of Genetics and Plant Breeding, CCSHAU, Hisar, Haryana, India*

India is the second largest producer of fruits, but average national productivity is quite low as compared to other countries. In fruit crops, pollination is mandatory for adequate fruit set and yield because the part of commercial importance is fruit which develops after the process of pollination and fertilization. If there is hindrance at any stage of pollination and fertilization, it would result in poor fruit set and ultimately a total loss of the crop. Most of the fruit crops are self- incompatible and require assisted pollination for optimum production. Proper pollination is not only required for fruit set but also necessary to get fruit of large size and proper attractive shape. In some multi seeded fruits like apple, pear and custard apple *etc.* seed number have a profound influence on both the size and shape of the fruit. There are several approaches to improve the pollination *viz.*, planting of more two or more compatible varieties in same orchard, pollinizer management (10-33% pollinizer or interplanting of two compatible varieties), pollinator management (honey bee and other native bees), hand pollination, top working of pollinizer branches, bouquet pollination, pollen dispenser, avoid the pesticide application during blooming, use of bee attractant pheromones and mechanical pollination through electrostatic duster or handmade duster. Honey bees are effective pollinators in fruit crops. Bee-HereR, BeeScentTM, eugenol, geraniol, citral and lemon grass extract, mainly diluted in water, honeybee pheromones, including the worker nasanov pheromone and queen mandibular gland pheromone were effective in attracting honeybees to orchards. Many pesticides are hazardous to bees. Large numbers of bees may be killed by the application of pesticides while the bees are located in the orchard. Proper pollination management through integrated approach is today's need to fulfil our tomorrow's requirement.

Key words: Fruits, honey bee, orchard, Pollination, Production

EFFECT OF SUBSTRATES, NUTRIENT RATIO AND SUGARS ON YIELD ATTRIBUTES OF *PLEUROTUS* SPP.

NARESH KUMAR BHADANA¹, GOPAL SINGH¹ AND ADESH KUMAR^{1,2}

¹*Department of Plant Pathology, S.V.P. University of Agriculture and Technology, Meerut, Uttar Pradesh-250110, India,* ²*Department of Plant Pathology, School of Agriculture, Lovely Professional University Phagwara, Punjab-144411, India*

Pleurotus spp. on different grain substrates i.e., wheat, sorghum, barley, oat and bajra were grown in bottles and obtained on 15th day were significantly superior than other grains spawn. Mycelial growth on bajra and sorghum was followed by oat grain barley (76.00 mm) and (75.66 mm). In case of *P. florida*, mycelial growth on jowar was followed by barley and wheat (88.66 mm), but in case of *P. djamor* mycelial growth on bajra (90.00 mm) was followed by wheat (88.00 mm). *The different combination of calcium carbonate and calcium sulphate with different ratio increases spawn growth in both the Pleurotus spp. The maximum spawn growth (90.00 mm) was observed in 0.2:1.5 ratio (CaCO₃:CaSO₄) in P. florida and 0.3:0.9 ratio (CaCO₃:CaSO₄) P. djamor.* *Pleurotus* spp. were grown in five sugars mixed in wheat grain viz. fructose, maltose, sucrose, starch and glucose. The results revealed that among all the five sugars, maximum mycelial growth (90.00 mm) was obtained in glucose on 15th day of inoculation. Followed by maltose (88.00 mm) in *P. florida* and fructose (87.33 mm) in *P. djamor*.

Key words: *Pleurotus* spp.; pH; Temperature; Dry mycelial Weight; Radial growth; Selective medium; Enriched medium.

HETEROSIS STUDIES IN BARLEY (*HORDEUM VULGARE* L.) UNDER HEAT STRESS ENVIRONMENT

NARESH PARASHAR¹, D.K. GOTHWAL², MAHESH SHARMA³ AND RATANLALSHARMA⁴

¹⁻³*Department of Plant Breeding and Genetics and* ⁴*Department of Plant Pathology, S.K.N. Agriculture University, Jobner, Jaipur-303329*

Barley (*Hordeum vulgare* L.) is an important *rabi* cereal crop grown throughout the temperate and tropical regions of the world. The present investigation was carried out to estimate relative heterosis and heterobeltiosis in barley genotypes to identify desirable cross combinations under heat stress for days to anthesis, duration from anthesis to maturity, days to maturity, plant height, number of effective tillers per plant, flag leaf area, number of grains per spike, peduncle length, spike length, 1000-grain weight, biological yield per plant, grain yield per plant and harvest index. The F₁ crosses were made in half diallel fashion using 10 genotypes. The experiment was conducted in randomized block design with three replications during *rabi* 2016-17. The results revealed sufficient degree of heterosis and heterobeltiosis for all the characters studied. On the basis of *per se* performance, heterosis and heterobeltiosis, the crosses RD-2035XRD-2052 and RD-2592XRD-2660 emerged as good cross combinations for grain yield per plant in heat stress environment.

Therefore, it could be concluded that these cross combinations may be exploited in future breeding programme for the development of good heterotic gene pool of barley for improving grain yield and other contributing traits under heat stress environment.

Keywords:-Barley, Heterosis, Heterobeltiosis, Heat Stress.

STUDY ON THE INTEGRATED APPROACH OF FUNGICIDES, BIOAGENTS AND PHYTOEXTRACTS FOR THE MANAGEMENT OF *COLLETOTRICHUM GLOEOSPORIOIDES* CAUSING THE TURMERIC LEAF SPOT DISEASE (IN-VIVO)

NASREEN MUSHEER* AND SHABBIRASHRAF

Department of Plant Protection, Aligarh Muslim University, Aligarh, 202002

Turmeric (*Curcuma longa* L.) is an important annual herbaceous rhizome producing medicinal plants which is also called as Golden spice due to the presence of yellow colour imparting pigments named as curcuminoids and help in Indian economy by trade policies. Hence study are concerned on the integrated management of turmeric leaf spot disease caused by *Colletotrichum gloeosporioides* under field conditions during 2017-2018 by applying three consecutive foliar spray at 45 days of intervals with fungicides, bioagents and phytoextracts. The significant result was determined by measuring the average of percent of disease index after three foliar spray were recorded with fungicides, Bilitox (50WP) at 0.05% concentration (47.23%), Carbendazim (50WP) at 0.05% concentration (49.51%), and Mancozeb (75 WP) at 0.5% concentration (52.35 %), bioagents *Trichoderma viride* at 3×10^6 cfu/ml (54.23%) and *Trichoderma harzianum* 3×10^6 cfu/ml (57.45%) and with phytoextracts Neem at 20% concentration (60.43%), Garlic at 20% concentration (61.53%), Tulsi at 20% concentration (63.53%) over the control (untreated plants) 68.41%. the above result showed that the fungicides spray gave the highly effective result followed by bioagents and plant extracts as compared to untreated plants.

Key words: Turmeric, Integrated approach, fungicides, bioagents, plant extracts, *Colletotrichum gloeosporioides*.

PRESENT SCENARIO ON STORAGE QUALITY OF POME FRUITS

NAVEEN KUMAR* ABHIVIVEK VINAY KUMAR KARDAM*****

Naveen Kumar, M.Sc. Department of Plant Pathology, Dr Y S Parmar UHF, Nauni Solan, **Abhivivek, M.Sc. Department of Entomology, Dr Y S Parmar UHF, Nauni Solan, *Vinay Kumar Kardam, M.Sc. Department of Plant Pathology, SKRAU, Bikaner*

Apples are rarely consumed directly at harvest but are usually stored for periods of up to 6 months to ensure a steady year round supply of high quality fruits. The major losses during this time result from infections with post-harvest pathogens as well as from post-harvest storage disorders such as scald, bitter pit, internal browning and water core. Over 90 different post-harvest phytopathogens have been described in apples, of which the most important are *Botrytis*, *Penicillium*, *Gloeosporium* and *Phytophthora* spp. Post-harvest decay in harvested fruit causes considerable economical losses. Fungicides are the primary means to control these losses. These infections may originate either from the field itself or from within the storage area, and their impact on fruit quality, depends on both pre-harvest as well as post-harvest factors. Post-harvest diseases on pome fruits are generally controlled by chemical treatments applied in packinghouses before fruit storage. Salicylic Acid as a natural and safe phenolic compound exhibits a high potential in controlling post-harvest losses of horticultural crops. Applying fertigation to fruit development phase and soil nitrogen content had a very important influence on fruit quality and storability. Appropriate nutrition supply produced more deeply coloured fruit that maintained their quality after storage for 4 months.

Keywords: Fertigation, pome fruits etc.

APPLICATION OF DOUBLE HAPLOIDS IN MAIZE BREEDING

NAVEENKUMAR, K.L.*¹ AND MAHANTHESHA, M.²

¹College of PG-Studies, CAU, Umiyam 793103, Meghalaya, India, Dept. of Genetics and Plant breeding, CCSHAU, Hisar, Haryana - 125004

Maize is one of the third most important cereal crops after rice and wheat. Uses of corn increases the demand is pushing to develop new hybrids and varieties to new regions or zones, challenging us to deliver specific products as quickly as possible. Doubled haploid technology dramatically increases the speed of the inbred development process by trimming off several time intensive generations of inbreeding, while making phenotyping and genotyping more predictive. This allows us to do more testing in the same amount of time to increase the rate of genetic gain and ensure that the products we advance are the best possible choices for our customers. Doubled haploids can be produced *in vivo* or *in vitro*. *In vivo* is tissue culture method but chance of more risk. Haploid embryos are produced *in vivo* by non occurrence; mainly two types of *in vivo* haploid can be differentiated in maize, and will lead to maternal and paternal haploids, respectively. For haploid induction *in vivo*, two genotypes are required a donor and an inducer. After pollination of the donor genotype with inducer pollen, the resulting offspring will typically consist of 90% hybrids and 10% haploids. In order to identify haploids, a system of dominant anthocyanin *R1-nj* selectable marker genes is used, as described by Nanda and Chase (1966). The inducer is

homozygous for the dominant marker gene *R1-nj*. When crossed with non-pigmented donors, it leads to a purple scutellum and a “purple crown” of the aleurone of F_1 kernels. *R1-nj* causes a colored endosperm and a colored embryo. If double fertilization has occurred, both endosperm and embryo are colored and the embryo is a diploid hybrid between donor and inducer. If the pollen only fertilizes the endosperm, while the egg cell remains unfertilized, the endosperm is colored and the embryo is colourless and haploid. If only the embryo is fertilized, then there will be no endosperm covering the seed, rendering the seed unable to survive. Self pollination results in a colourless embryo and colourless endosperm, depending on the parent plant. These two characteristics are used as embryo and endosperm markers, respectively. From the haploid methods we can maximum genetic variance in line *per se* and testcross trials, high reproducibility of early-selection results, high efficiency in stacking targeted gene arrangements, simplified logistics and high cost-savings are possible due to reduced expenses for the selfing program, handling and shipping of seed batches, and for maintenance breeding.

Keywords: Hybrids, varieties, Doubled haploids and Selectable marker.

IMPORTANCE OF MAIZE LANDRACES IN CROP IMPROVEMENT FOR CLIMATE CHANGE

NAVEENKUMAR, K.L.*¹ AND MAHANTHESHAM²

College of PG-Studies, CAU, Umiam 793103, Meghalaya, India, Dept. of Genetics and Plant breeding, CCSHAU, Hisar, Haryana - 125004

Maize (*Zea mays* L.) is not only of worldwide third most important crop after wheat and rice and used as a food, feed and as a source of diverse industrially important products, but is also a model genetic organism with immense genetic diversity. Maize landraces remain deeply intertwined into the traditions and cultures of many of the world's rural communities and in India especially North Eastern Hill (NEH) regional states. However, due to recent new variety development activities resulting from the “Green Revolution”, landraces are in serious jeopardy of being totally lost within the next 50 years. The reduced use of landraces can be traced back to the beginnings of the “Green Revolution”, when there was a substantial worldwide increase in the use of new modern cereal crop varieties that provided increased productivity compared to the varieties that were currently in use that had limited genetic improvements, but recent climate changes effect the plant growth and development leads miner disease and pest become major, biotic stress decrease the yield and difficult feed increasing population. Mitigating this problem is to search source of resistance that's best and cheapest is landraces. Although it was first domesticated in Mexico, maize landraces are widely found across the continents. Several studies in Mexico and other countries highlighted the genetic variability in the maize germplasm. Recommended climate change adaptation strategies include farmers increased use of heat and drought stress-tolerant maize. Farmer adoption of improved germplasm has been disappointing because of inefficient seed input chains and farmers preference for landraces for culinary, agronomic and cultural reasons. Scientists have tended to overlook the fact that maize landraces have a critical role to play in climate change adaptation. Landraces may already exist that are appropriate for predicted climates. Furthermore, within the primary gene pool of maize and its wild relatives there exists unexploited genetic diversity for novel traits and alleles that can be used for breeding new high yielding and stress-tolerant cultivars. The breeding component of adaptation strategies should focus more on improving farmers' landraces.

Key words: Genetic diversity, Germplasm, Green Revolution and Adaptation.

INNOVATIVE TECHNOLOGIES FOR SUSTAINABLE IPM

¹NAVEEN * AND ²KULDEEP

Department of Entomology, College of Agriculture, CCSHAU, HISAR-125004(Haryana), Department of Soil Science, College of Agriculture, CCSHAU, HISAR-125004(Haryana)

Integrated pest control is a pest management system that, in the context of associated environment and population dynamics of the pest species, utilizes all suitable techniques and methods in as compatible manner as possible and maintains pest populations at levels below those causing economic injury. The modern concept of pest management is based on ecological principles and involves the integration and synthesis of different control tactics into a pest management system. Integrated pest management (IPM) in turn is a component of the agro ecosystem management technology for sustainable crop production. The zero or reduced tillage system in rice-wheat cropping sequence (RWCS) is relatively a new concept which entails adoption of wheat sowing method that involves direct drilling of wheat seeds into rice residues after the harvest of rice crop. It has influenced the species diversity, status, biology, ecology and carry-over of insects and beneficial species. To manage insect pests in an eco-friendly manner, a pest-suppressive agro-ecosystem has to be considered which is designed by identifying a suitable intercrop having insect pest deterrence, and a border crop enhancing natural enemy activity by acting as a refugium. Thus, crop diversification can be effectively integrated with bio intensive IPM packages. The development of pest control methods that can minimize the use of pesticides is required for pest management. Furthermore, use of pest-resistant crops and varieties, pest repellent plants, adoption of cultural practices that prevent buildup of pests, use of cropping system such as crop rotation, intercropping, etc., and the use of bio pesticides and semiochemicals, etc. can be used for pest control.

Keywords: IPM, Pest, Insect

AEROPONICS: AN ADVANCED APPROACH FOR SOILLESS VEGETABLE PRODUCTION**NAVJOT SINGH DHILLON*, PARVEEN SHARMA, PARDEEP KUMAR AND PALVI MEHTA***Department of Vegetable Science and Floriculture, Himachal Pradesh Krishi Vishvavidyalaya, Palampur-176062*

The word "aeroponic" is derived from the Greek word "aero" means air and "ponos" means labor or work. The roots hang in the air and are misted with nutrient solution. The misting is usually done every few minutes. There are many advantages of growing plants aeroponically. Here nutrients are fed directly to the roots, as a result plants grow faster with smaller roots, plants may be grown closer, only 1/5th of overall space and 1/20th of total water is needed to grow plants under aeroponics in comparison to soil-based culture. There is no chance of soil-borne insect-pest, disease attack or weed infestation too. Aeroponic culture provides efficient nutrient regulation, higher density planting, and leads to increase yield having 6 to 7 times more output than conventional greenhouses production along with better quality of the produce. The industry is expected to grow exponentially in future, as conditions of soil growing is becoming difficult. Specially, in a country like India, where urban concrete conglomerate is growing each day, there is no option but adopting soil-less culture, help to improve the yield and quality of the produce so that we can ensure food security. However, government intervention and Research Institutes interest can propel the use of this technology.

Keywords: aeroponic, soilless, yield, quality, food security

PROTECTED VEGETABLE CULTIVATION: A GOOD OPTION FOR DOUBLING THE FARMER'S INCOME**NAVNEET SINGH AND RAVINDER SHARMA***Department of Social Sciences, Dr Y S Parmar University of Horticulture & Forestry, Solan- 173 230, Himachal Pradesh, India*

Vegetables play a major role in Indian economy by producing higher returns per unit area and time, besides, providing nutritional and economic security. Vegetables have higher productivity, shorter maturity cycle, better crop diversification and intensification, high value and provide greater income leading to improved livelihoods. By providing better employment opportunities to family labour, vegetables solve the problem of disguised unemployment of Indian farmers. Production of vegetables under protected conditions involves protection of production stages of vegetables mainly from adverse environment conditions such as temperature, hail, scorching sun, heavy rains, snow and frost. The primary data were collected by personal interviews of the selected farmers with the help of a specially designed schedule. Simple statistical tools like averages and percentages were used for processing the data. An attempt was made to study the comparative economics of tomato and capsicum cultivation under protected and open field conditions in Solan district of Himachal Pradesh. Comparative economics analysis revealed that the cost of cultivation of capsicum under polyhouses were higher as compared to open field conditions by Rs. 20755.63/250 m², Rs. 34769.90/500 m². The net returns from capsicum under protected conditions, were higher as compared to open field conditions Rs. 246.94/250 m², Rs. 15792.38/500 m². The net returns from polyhouse cultivation worked out Rs. 1725.64/250 m² and Rs. 12907.68/500 m² more as compared to open cultivation of tomato. The results of the study revealed that the vegetable cultivation under polyhouses have contributed to the yield significantly and increased in income of farmers.

GENETIC RESOURCES AND ADVANCES IN GENETIC IMPROVEMENT OF SEED SPICES*** NAVNEET SINGH, SHAUNAK SINGH, RAVI PRATAP SINGH***Department Of Vegetable Science, N. D. University Of Agriculture & Technology, * Kumarganj, Faizabad (U.P.),*

Spices are those plants, the products of which are made use of as food adjuncts to add aroma and flavour, while condiments are those plants, the products of which are used as food adjuncts to add taste only. India is the largest producer, exporter and consumer of spices in the world. India is often referred as "land of spices". This is because many of the spices grown in the world are native to India. Spices cover an area of 3535 M ha with production of 7077 M tonnes all over India (Anonymous, 2017) Seed spices are annual herbaceous in nature. These are used as whole or ground form, mainly for flavouring and seasoning of food. The seed is commonly used as traditional medicine for treatment of congestion of upper respiratory passages, colic, flatulence, dysentery, diarrhoea, chronic cough, and enlargement of liver and pharmaceutical preparation. Major seed spices are Fenugreek (*Trigonella foenum-graecum* L.), Coriander (*Coriandrum sativum* L.), Cumin (*Cuminum cyminum* L.), Fennel (*Foeniculum vulgare* Mill.) and Ajwain (*Trachyspermum ammi* L.). Most of seed spices are cross pollinated in nature except Fenugreek. Among seed spices Coriander grown on largest scale in India followed by cumin, fenugreek, fennel and ajwain. Rajasthan is the leading state in production of seed spices, while Madhya Pradesh has maximum area under seed spices.

STUDIES OF TRANSITION METAL COMPLEXES AND THEIR BIOLOGICAL EVALUATION**NEELAM KUMARI AND PRATIBHA***Department of chemistry, Meerut College, Meerut, U.P. India, Department of Chemistry Mewar University Gangrar Chittorgarh 31290 Rajasthan, India*

A novel series of macrocyclic ligand of Cu II were synthesized by using condensation reaction between macrocyclic ligand and corresponding transition metal salts. The Cu II complexes $[CuLx_2]$ where $L = N_4$ donor macrocyclic ligand and $X = Cl^- NO_3^-$ and $(CH_3COO)^-$ have been synthesized and characterized by elemental spectra. The molar conductance measurement of crown ether complexes of ligand LF and LG show that complexes are in 1:2 electrolytes in nature and may be formulated as $[Cu(L)]X_2$ where $L=LF$ & LG. The biological activity against different plant pathogenic fungi has been evaluated. The EPR studies suggest the tetragonal geometry for all the chloride, nitrate and acetate complexes with all the seven ligand.

KEYWORD : Tetra aza macrocyclic complexes . Spectral data, Metal Complexes, Synthesis antifungal activity.

A SURVEY ON SMALL FARMER PEST CONTROL PRACTICES FOR WATERMELON IN ALLAHABAD DISTRICT, U.P.**NEELAM YADAV AND NEERJA AGRAWAL***Department of Entomology, Chandra Shekhar Azad Univ. of Agri. & Tech., Kanpur (U.P.)*

In response to increased pest problems, small farmers use pesticides against production of watermelon crops, which could rise environmental and health concerns. An intensive survey was conducted in four villages of Allahabad viz., Mundera, Jhalwa, Peepalgao and Rajapur in year 2016. 60 farmers were interviewed about the type of sprayer and pesticides they use in fruit cultivation and the frequency of applications. Use of personal protective equipment was low. Out of total respondents of farmers from the different villages of Allahabad district, the types of pesticides used in watermelon were insecticides (50%), biopesticides (45%) and conventional practices (5%). This paper assesses the potential risk of pesticide use by smallholder farmers in the Allahabad district, Uttar Pradesh by examining pesticide usage, application methods, pesticide drift and health effects among farmers with different levels of income and market access.

Key words: Farmer, Allahabad, Pest control, Watermelon, Insecticides

ROLE OF TECHNOLOGY ADOPTION ON MARIGOLD PRODUCTION THROUGH FRONT LINE DEMONSTRATION**NEERJASHARMA¹, DEEPSHIKHA², VINOD GUPTA, SANJAY KHAJURIA, AMIT GUPTA AND SHALINI KHAJURIA³***^{1&3} K. V.K Samba, SKUAST-Jammu. ²Department of Agriculture, Jammu.*

Marigold is one of the important commercial crop among floriculture supplementing the regular income to small and marginal farmers of the Kathua district of J&K state. Jammu being a city of temples consumption of flowers is more, but as compared to consumption production is very less. However, the major constraints of marigold cultivation are low productivity due to the lack of good quality seed, non adoption of recommended package of practices and lack of awareness regarding the economics of the crop as compared to cereals. To solve this problem, front line demonstration were conducted at the farming situation of Kathua district with the participation of farmers after the baseline survey. Front line demonstration is an applied approach to demonstrate technologies among the farmer. The cultivation practices in this FLD (use of improved variety, proper nursery techniques, balance dose of fertilizers, important inter-culture operations and plant protection measures) increased the yield by 53.78 percent on an average over the farmer practice. The highest extension gap was 72.75q/ha while the technology index, which is inversely correlated to the feasibility of the improved technology in the farmers field was 24.3 percent. The adoption of improved technology under FLDs resulted in higher gross returns (Rs 728000/ha), net return (Rs 643517/ha) and benefit:cost ratio (1:7.61) as compared to farmer practice.

CURRENT PROSPECTS FOR THE USE OF BOTANICALS IN INTEGRATED PEST MANAGEMENT**NEERJASHARMA¹, DEEPSHIKHA²***¹ K. V.K. Samba, SKUAST-Jammu ²Department of Agriculture, Jammu*

Botanicals have been in use for a long time for pest control. A product of species co evolution, these compounds offer many environmental advantages. However, their uses during 20th century have been rather marginal compared with other bio-control methods of pests and pathogens. Overdependence on chemical pesticide in pest control has brought the problems like (1) pest resistance to pesticides (2) resurgence of pests (3) toxic residues on food, water, air and soil, (4) elimination of natural enemies and disruption of the ecosystem and minor pest assuming major status. On the other hand, use of botanicals offer a good alternative to manage the insects pests and diseases in an eco-friendly way. Because they are naturally occurring, high specificity to target pests, no adverse effect on beneficial insects, resistance development to them is slow or less common and no environment hazards. Due to the above reasons the role of biopesticides and bioagent is considered as a potent and reliable tool in IPM to manage insects pests. The insecticides of plant origin

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

extracted from seeds, flowers, leaves stem and roots are termed as botanical insecticides. Nicotine, rotenone, sabadilla, ryania, neem based products and toosendanin are more important botanicals. In addition to that efforts are being made to make phytochemicals from annonin, citrus limnoides, karanj and Mahua. Botanical pesticides exert a range of behavioural and physiological effects on the colonization, development, growth, survival and multiplication of insects. The toxic principles in these botanicals are mostly alkaloids, heterocyclic nitrogenous compound with marked physiological activity. Botanical pesticides can be integrated with the use of parasitoids and predators, microbial pesticides and even synthetic chemical pesticides to achieve greater efficiency in pest control. However, bio-pesticides and natural enemies of pests are likely to play an important role in IPM in modern agriculture for controlling pests of vegetables and fruit crop in near future beside grain crops as well as in conserving environmental quality.

SERICULTURE FARMING: MONEY SPINNER FOR FARMERS

NEERU DUMRA*¹, KIRAN BALA²

1. Department of Entomology, CCS Haryana Agricultural University, Hisar-125004, India, 2. Department of Entomology, Govind Ballabh Pant University of Agriculture and Technology, Pantnagar-263145, India

Silk is the most elegant textile and known as the "Queen of Textiles" all over the world. Silk has been intermingled with life and culture of the Indians due to rich and complex history in silk production and its silk trade dates back to 15th century. India's traditional and cultural elements in the domestic market and an amazing diversity of silk garments (a look and feeling of grandeur that no other cloth can equal) that reflect geographic specificity have helped the country to achieve a leading position in the silk industry. Sericulture industry provides employment to approximately 8.51 million persons in rural and semi-urban areas in India during 2016-17. Of these, a sizeable number of workers belong to the economically weaker sections of society, including women. A successful silk industry will attract investors and private entrepreneurs subsequently making significant contributions to the national economy. Therefore, it provides livelihood opportunity for million persons owing to high employment oriented, low capital intensive and remunerative nature. Due to its significant importance and usefulness, many attempts have been done in various parts of the world for the extensive production of silk. Scope for frequent cash accrual round the year has brought mulberry sericulture to a comparable level with other agricultural cash crops grown in the similar agro-climatic condition. Now it has become a highly remunerative agro-based cottage industry, combining both agriculture and industry, the final product is silk. Besides meeting the domestic demand, silk is also exported in various forms and now this sector is important foreign exchange earner in India.

Key words: Employment, national economy, remunerative, sericulture, silk industry

PHOSPHORUS DEFICIENCY A THREAT TO SOIL

NEETAMAHAWAR

Department of Soil Science & Agricultural Chemistry, Jawaharlal Nehru Krishi Vishwavidyalaya, Jabalpur, (MP) India -482004

Phosphorus is referred to as the "king-pin" in Indian agriculture and also as "energy currency" of the plants. P is second essential growth limiting macro-element next to nitrogen as an inorganic nutrient required by both plants and microorganisms. Relative abundance of P ranks 10th after O, Si, Al, Fe, Ca, Na, K, Mg, Ti in earth's crust. Phosphorus is taken up from the soil solution by plant roots mainly as primary orthophosphate ions (H_2PO_4^-) and secondary orthophosphate ions (HPO_4^{2-}). However, only a minute fraction (0.02 to 0.10%) of total phosphorus is present in soil solution with concentrations 0.1 to 1 $\mu\text{g/g}$ at any one time. 0.5-10% is in the readily available pool capable of releasing P to the soil solution and more than 80% of P is immobile in fixed portion adsorbed as Fe/Al/Ca hydroxide complexes generally known as "initial reaction products" which are slowly soluble and is not available for utilization by plants due to adsorption, precipitation or conversion to organic form. Phosphorus deficiency is widespread in the Indian as well as world soils and estimates forecast for no P-reserves by 2050. Hence, the limiting levels of available P necessitates the use of commercial fertilizers to supplement P for crop production to ensure food security in India as well as worldwide. Hence, we require the development of new techniques that enable the use of some indigenous, cheap, organic and sustainable P sources like rock phosphate being classified as low, medium and high grade with <25%, 25-30%, >30% P_2O_5 respectively. PGPRs used as biofertilizers along with RP are the best alternative to chemical fertilizers as they reduce the cost of crop production and are eco-friendly. Organic acids like citric, oxalate, malate and tatarate, gluconic, fulvic, humic accelerates the phosphate dissolution rates. Low-grade RP could be directly applied to soil as a source of P to crop plants along with acidifying materials such as elemental sulphur (S), pyrites, gypsum, etc. Enrichment of biogas sludge and soil with RP can be used as an efficient and cost effective phosphate fertilizer for different crops in acid as well as alkaline soils. Fertilizers alone cannot solve the purpose of fulfillment of plant needs as their over usage leads to high runoff losses causing degradation of water reservoirs mainly through eutrophication posing a threat to sustainable crop production. The GPS/GIS-based soil fertility mapping can enhance the judicious use of P fertilizers by preventing their over and under usage.

Keywords:- Rock phosphate, Phosphorus fixation, organic acids, PGPRs etc.

INHERITANCE OF WHITE RUST RESISTANT IN LOCAL GERMPLASM OF BRASSICA JUNCEAL.**NEHA DAHIYA*, RASHMI, RAM BHAJAN AND USHA PANT***Department of Genetics & Plant Breeding, College of Agriculture, G. B. Pant, University of Agriculture & Technology, Pantnagar, Uttarakhand-263145*

Brassicas are important source of vegetable oils in the Indian continent as well as in the world by contributing 15% to the total oilseed production. The yield of this crop suffered due to various abiotic and biotic stresses out of which White rust can capable of causing 50 to 89.8 % losses. Most of release cultivars are defenseless to this disease. The chemical control has not been found much effective. Therefore, cultivation of disease resistant varieties seems to be the most practical and affordable means to combat against this disease. Some sources of resistance have already been identified however; the hereditary control for white rust isn't completely comprehended (Thakral and Singh, 1986). Information on the nature and mode of inheritance of genes controlling resistance and their stability under various agroclimatic conditions is imperative for effective utilization of genetic resistance against diseases in the breeding programme (Chauhan and Sharma, 2001). In the present study, newly developed white rust resistant line PWR-15-8 was crossed with two susceptible varieties RGN-73 AND PM-25 to generate 2 families for comprehending inheritance of white rust resistance in the PWR-15-8. Results showed that all the plants in all the F_1 s were resistant and resembled the resistant line used as P_1 (PWR 15-8), suggesting that resistance in this line is a dominant trait. The distribution of resistant and susceptible plants in F_2 generation gave a segregation of 3 resistant: 1 susceptible plants, indicating thereby that the resistance is monogenically dominant over susceptibility. As expected the observations on back crosses of F_1 s with their respective susceptible strains (BC_2) showed segregation of 1 resistant: 1 susceptible plants, while all BC_1 plants were resistant. These results confirm the single gene control of white rust resistance in PWR 15-8.

PROSOPIS CINERARIA A LIFELINE TREE OF DESERT ECOSYSTEM**NEHA SAINI AND KAJAL MEHTA***Dept. Offorestry, CCS Haryana Agriculture University, Hisar 125004, India*

Agriculture system is fragile in the arid regions and mostly dependent on rainfall. Generally the soil in the region are poor in fertility status and low in organic matter. Traditional farming with the trees or agroforestry (combination of trees, crops and pastures) with suitable selection of tree species such as nitrogen fixing trees or multiple tree species will help in adding organic matter and improving fertility status of soil. Such a tradition of cultivating trees has been practiced in western Rajasthan since historic times. One such tree, Khejri (*Prosopis cineraria*) is an indigenous tree of tropical dry and thorn forest of North western parts of India. The tree is also called King of Great India Desert due to its multiple benefits in conserving the fragile desert ecosystem. Though the tree is present in scattered form in arid environment, it is beneficial to maintain tree density of 100- 200 trees per hectare that can increase crop yield by 15- 20 percent compared to sole crop. The tree is lopped for fodder and fuelwood. Lopping practices in winter helps for winter crops. *P. Cineraria* provides fruit of 350- 1040 kg / tree used as vegetable. In addition, *P. cineraria* provide utilizable biomass of 20 Mg per ha (tree density 208 tree/ ha). Including leaf fodder of 1 Mg/ha per year when fully grown. In the light of present day situation, it can be said that Khejri tree serves as 'island of fertility' in an ecosystem where resources are very much limited. Thus, more attention should be focused on saving the 'Lifeline tree of desert ecosystem' for evergreen agriculture productivity and livelihood security

Keywords: *Prosopis cineraria*, King of Indian desert, agroforestry tree,

GRAFTING IN VEGETABLE CROPS**NEHA VERMA^{*1} AND JYOTI VERMA^{*2}***¹ Department of Vegetable Science, PAU Ludhiana Punjab 141004, ²Department of Floriculture and Landscaping, PAU Ludhiana Punjab 141004*

Grafting is a method of propagation, done by utilizing selective rootstock and scion combinations to develop as a single plant for tolerance against biotic and abiotic stresses that directly influences the production of vegetable crops. In addition, grafted plants may have higher yields, improved tolerance to environmental stresses such as high boron, soil salinity and low soil temperatures even in off season (Oda M, 2007). It is a rapid alternative means to the moderately slow breeding methodology. Additionally, the availability of efficient grafting machines and grafting robots can increase grafting speed, increase the survival rate of grafted plants and ultimately encourage cultivation of grafted vegetable worldwide (Lee and Oda, 2003). In spite of its advantages, there are some problems associated with grafting. These include the additional cost, graft incompatibility that commonly appears to cause physiological disorders, reductions in yield, fruit quality and flower formation. Using resistant rootstocks (hybrids), cultivated species and other wild species of the same genera resistant to *Meloidogyne spp.*, *M. incognita*, *M. arenaria* and *M. javanica* have been successfully used. Resistant rootstocks of tomato 'LAO-7002', 'LAO-7003'; of pepper 'LINEM' and wild species *Solanum torvum* were identified (Gonzalez *et al.*, 2008) as resistant to *Meloidogyne spp.* Initiating or increasing the use of grafted plants should be done only after the benefits and risks of grafted seedlings have been fully understood (Edelstein, 2004).

Key words: Grafting, advantages, problems, vegetable crops.

NATURAL RESOURCES MANAGEMENT AND THEIR CONSERVATION

[†]NEHA, ANIKET DIWEDI[†] & B. S. PRAJAPAT^{*}

CCSHAU, Hisar-125004, Haryana, CCSHAU, Hisar-125004, Haryana, MPUAT, Udaipur--313001, Rajasthan

Although, India is endowed with rich and vast diversity of natural resources, particularly soil, water, weather, multipurpose trees and agro bio-diversity. The extremes stress on these resources leading production fatigue, poor resource-use efficiency and countries rich and bountiful biological endowment is showing sigh of stress. The major issue which directly or indirectly affecting the agricultural production system sustainability are identified as follows: shrinking land resources, water scarcity, low input use efficiency, soil organic matter depletion, loss of biodiversity, salinity and alkalinity, multiple nutrient deficiency, negative nutrient balance and low fertilizers use efficiency, waterlogging, industrialization and intensification of agriculture and global climate change. Therefore, it is important to preserve these agriculturally valuable resources, so that they continue to be useful under prevalent biotic and abiotic pressures. An integration of modern tools and techniques like conservation agriculture (Bed planting, Paddy transplanter and laser land levelers), Fertigation, Organic farming, crop-diversification strategies, precision farming, site-specific nutrient management, bio-intensive farming (Raised beds, Broad bed and furrow, furrow irrigated raised bed, intensive planting, intercropping, composting, companion planting and whole energy system) and farming system research approach have shown promise to enhance resource-use efficiency on the one hand and to conserve valuable resources on the other. The ICT-based options like GIS, Remote Sensing and Nutrient Experts[®] has powerful tools for managing resources in spatial, temporal and location specific mode. The natural resource in the country needs its appropriate and scientific use.

Key words: Resources use efficiency, Soil and Water Resources, Conservation Agriculture, Precision Farming & Bio-intensive Farming.

DOUBLING THE FARMERS INCOME THROUGH INNOVATIVE APPROACH

NIDHI

Department of Seed Science & Technology, CCS Haryana Agricultural University, Hisar-125004, India

Doubling the Farmers income by 2022, would require some specific policy and institutional reforms that take into account identification and targeting of low income farmers particularly from the regions where the required infrastructure for overall agricultural development is lacking. The low income and increasing disparity between income of a farmer and non- agricultural worker (almost double) is one of the reasons for agrarian distress. The low and highly fluctuating farm income is detrimental to growth of farming and further farm investments, and forces the cultivators to leave farming. Therefore it is very crucial to understand the income dynamics of the farm households so that various strategies can be devised to improve farmers' income. Inflation in agricultural commodities will lead to double the farmers income in the nominal terms in much shorter period but Government's intention appears to double the real income of farmers. Many new initiatives have been taken by the Government for increasing the farmers' income such as: i) "per drop, more crop", ii) availability of quality seeds, iii) soil test based nutrient management, iv) post-harvest crop losses- large investments in warehousing and cold chains, v) value addition by the farmers, vi) creation of a national agricultural market and having e-markets to link farmers to market, vii) Pradhan Mantri Fasal Bima Yojana, viii) high priority to diversification towards high value activities horticulture, dairying, food processing, poultry, sericulture, bee keeping and fisheries, etc. The strategy to double the income would demand sustainable intensification, diversification, improved resource use efficiency and resilience in farming that is economically rewarding. There is every possibility not only to double the income of farmers through enhancement in productivity, changes in cropping pattern and inspire additional income through supplementary activities but also provide stability in farmers income.

Key words: Farmers income, agricultural development, intensification, diversification, value addition

MATING DISRUPTION: MECHANISM AND CONSTRAINTS

NIRAJ GULERIA^{1*}, RAKESH²

¹Division of Entomology, ICAR-IARI, New Delhi, India, ²Division of agricultural chemicals, ICAR-IARI, New Delhi, India

Male moths generally find their mates by following the females' pheromone plume to its source. Mating disruption consists of deploying dispensers of synthetic sex pheromone in crop areas to decrease the likelihood of a male finding a calling female, thereby preventing the occurrence of mating and egg fertilization. But the principal mechanism of insect mating disruption not understood so far. Mechanisms of mating disruption closely align with those established for enzyme inhibition, falling into two major categories-competitive and noncompetitive. Competitive mechanisms include competitive attraction, induced allopatry, and induced arrestment. Non-competitive behavioral mechanisms include camouflage of the female plume. Desensitization of males via either sensory adaptation or habituation, and sensory imbalance caused by interference with the male's ability to perceive the pheromone plume. Under Noncompetitive disruption, males, females, or the signal from females are already impaired when sexual activity commences. Hybrid profiles are

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

possible when some males within the population begin the activity period already incapacitated, while those not pre-exposed have the capacity to respond either to traps or pheromone dispensers. Variety of pheromone-dispensing technologies in mating disruption has been developed over the years, and many of them have shown promise and success in the market. Mating disruption products have been developed for more than 20 insect species and are used on more than 750,000 hectares world, however Codling moth (*Cydia pomonella* L.) and oriental fruit moth (*Grapholita molesta* Busck) have gained the most attention.

Key words: Arrestment, competitive, inhibition, male, mating disruption

PRESENT STATUS OF IPM PROGRAMMES IN INDIA: CHALLENGES AND PROSPECTUS

NITESH SHARMA

Department of Entomology, Dr YSP University of Horticulture & Forestry, Nauni, Solan 173 230 India

Insect pests are well recognized as one of the major limiting factors in enhancing and sustaining agricultural production in India. Recent improvements from research brought considerable change in the cropping systems and allowed farmers to grow several crops throughout the year, which were very seasonal in the past. This also brought significant shift in the insect population dynamics and change in the status of several insect pests. Recent data revealed that 93% of the farmers in India had adopted chemical control, 51% farmers get their plant protection advice from dealers, while 22% from extension officials and majority of the farmers (73%) initiate the plant protection based on the first appearance of the pest, irrespective of their population, crop stage, and their damage relationships. The cost of plant protection on various crops ranged from 7 to 40% of the total crop production cost. Though integrated pest management (IPM) has been advocated for the past two decades, only 3.2% of the farmers adopted IPM practices in various crops. IPM research in the past decade brought out changes in the farmer's attitude in pest management, which results 100% reduction in pesticide use in different crops. The recent farmer participatory approach working in a consortium mode proved very effective in the exchange of technology. Though the results are encouraging, there is a need to further strengthen the IPM adoption in Indian agriculture through increased investments in both basic as well as applied research in plant protection to overcome the prevailing three evil "Rs" (Resistance, Resurgence, and Residues). To be more effective, readdressing the policies for encouraging eco-friendly options and strengthening extension, involving farmers should be considered as high priority.

POST HARVEST TOOLS AND MACHINES FOR PEPPER AND TURMERIC

***NITIKA KUMARI, **RAJARAM BUNKER AND *HANSRAJ DHAKAR**

**Department of Plant Pathology, **Department of Horticulture, College of agriculture, Swami Keshwanand Rajasthan Agricultural University, Bikaner-334006*

India is origin of seed spices and condiments. It is the country which act as the outlet for the spread of spices to the whole world. A wide variety of spices are grown in India which are consumed within as well as exported to other countries. But the manhandling of the harvested produce as well as lack of proper processing leads to large amount of losses and degraded quality. The harvesting and post-harvest practices followed in seed spices are unhygienic which results in contamination of the products with foreign matters like stalks, dirt, sand, stem bits etc. The seeds are separated by beating the harvested and dried plants with bamboo sticks or rubbing the plants manually by hand or trampling under the feet of the cattle. In order to make the harvesting as well as the processes followed thereafter easy, time saving and cost effective various technological machines and tools have been invented. Traditionally pepper berries were separated from the spikes by trampling under the feet which is unhygienic and labour intensive. To overcome this the pepper threshers are used which are mechanically operated, labour saving and separates berries in a hygienic way. Fresh turmeric is cured for obtaining dry turmeric. Curing involves boiling of fresh rhizomes in water and drying in the sun. Over cooking spoils the colour of the final product while undercooking renders the dried product brittle. In conventional curing where the rhizomes are boiled in copper or galvanised iron or earthen vessels there are chances for overcooking or undercooking. Improved scientific cooking involves using boilers and perforated trough made of GI or MS sheet extended with parallel handle. This ensures optimum cooking of turmeric, which provides better colour and quality to the final produce. Dried turmeric has a poor appearance and rough dull colour outside the surface with scales and root bits. The appearance is improved by smoothening and polishing the outer surface by manual or mechanical rubbing. Manual polishing is done by rubbing the dried turmeric on a hard surface or trampling them under feet by wrapping in gunny bags. Manual polishing is an unhygienic practice, which affects quality of the product. The improved method of polishing turmeric is by using hand operated / power operated polishers. This ensures hygienic and effective polishing which gives better appearance to the product. Hence it is proposed to popularize the practice of using improved polishers for polishing turmeric.

Key words : Post harvest, pepper thresher, turmeric boiler, turmeric polisher

STATUS AND PROBLEMS OF BEEKEEPING IN BAGHPAT DISTRICT OF UTTAR PRADESH**NITIN KUMAR NAG¹, LALIT KR. VERMA² AND PUKHRAJ SINGH³***Deptt. Of Ag. Economics, J.V. College Baraut Uttar Pradesh - 250611, Deptt. Of Ag. Economics, J.V. College Baraut Uttar Pradesh - 250611*

Beekeeping as a village industry is of considerable importance but in study area it requires a lot of improvement in apicultural as well as in agricultural practices. Most of the beekeepers are facing problems due to lack of knowledge of bee management technology and related skills. This small cottage industry may be called in infancy in Baghpat district of Uttar Pradesh. Crop diversification, which can provide continuous succession of blooming bee forage, is urgently required. There must be a regional bee research and training centre to provide guidelines against threats to beekeeping like varroa mite and other serious bee diseases. Honeybees not only play a vital role in pollination of various crops but also provide honey, bees wax, royal jelly, propolis and bee venom which is useful products from medical and commercial point of view. So beekeeping is the practice of keeping and manipulating honey bees, which contribute immensely to the welfare and economy of mankind. Success of this small cottage industry depends upon planned bee management technology. Before developing an infrastructure for beekeeping in particular vicinity, it is important to recognize the problems to be faced during and after the establishment of bee keeping industry.

Keywords: Apis mellifera, Beekeeping, Bee behaviour, pollination and Queen rearing.

EFFECT OF TEMPERATURE ON MORPHOPHYSIOLOGICAL TRAITS WITH RESPECT OF GRAIN YIELD OF BASMATI RICE**NITIN MAURYA, O.P.SINGH, S.N.SINGH, AND PAWAN GAUTAM***Department of Crop Physiology, C S Azad University of Agriculture and Technology Kanpur, Uttar Pradesh, India*

The field experiment was conducted at Chandra Shekhar Azad University of Agriculture and Technology, Kanpur (U.P.), during kharif season 2016 and 2017. The design in split-plot with three replication and three dates of transplanting i.e., first date of transplanting (D1), second date of transplanting (D2) and third transplanting (D3) conditions were allocated in the main plots and four basmati rice varieties V1 (PB-1), V2 (PB-1509), V3 (PB-6), and V4 (PB-1121), in sub plot. The significantly higher to plant height in cm first date of transplanting i.e., (D1) with 31.35 and 32.87 cm at 30 DAT, 72.79 and 73.36 cm at 60 DAT, 90.80 and 91.04 cm at 90 DAT, 99.20 and 98.46 cm at harvest stage (DAT), while minimum in third transplanting date (D3) with 20.37 and 21.56 cm at 30 DAT, 64.28 and 65.82 cm at 60 DAT, 81.32 and 82.91 cm at 90 DAT, 89.46 and 91.11 cm at harvesting stage of concerning years respectively. observed significantly higher plant height with variety V4 i.e., 28.30 and 29.48 cm at 30 DAT, 74.37 and 75.61 cm at 60 DAT, 91.86 and 92.40 cm at 90 DAT, 102.25 and 103.02 cm at harvest DAT followed by variety V1 with 26.90 and 28.60; 69.12 and 70.43; 87.84 and 89.10; 96.23 and 97.39 cm meanwhile, minimum in variety V2 with 23.17 and 24.08; 63.05 and 63.89; 78.97 and 80.72; 83.89 and 85.10 experimentation, respectively.

Keywords: Condition, rice, transplanting and variety.

GROWTH AND PRODUCTIVITY OF BARELY (HURDIUM VULGARE L.) AS AFFECTED BY SOWING METHODS AND NITROGEN FERTILIZER LEVELS**OLA Z. EL-BADRY AND EL-SAYED M. GHEITH***Faculty of Agriculture, Cairo University, Egypt Department of Agronomy, *Corresponding author: Ola Z El-Badry*

Growth and productivity of barely (Hurdium vulgare L.) as affected to two sowing methods (drilling and broadcasting) and three nitrogen levels, i.e. 60, 80 and 100 kg N/fed. (one feddan = 4200m²) were studied at the Agricultural and Experimental Research Station at Giza, Faculty of Agriculture, Cairo University, Egypt during two successive winter seasons 2015/2016 and 2016/2017. The experiments design was split-plot in randomized complete block design in four replications. Results indicated that both of sowing method and nitrogen levels significantly affected all growth characters, except leaf area index in the second season, as well as grain yield and its related favorable, except spike length and grain weight/spike, in both seasons. Increasing nitrogen levels up to 80 kg N/fed. caused an obvious increase in net assimilation rate, plant height, number of spikes/m², spike length, weight of grains/spike, grain yield, straw yield and harvest index. On the contrary, number of days to 50% heading, leaf area index and crop growth rate produced the maximum values at 100 kg N/fed. Drilling method exceeded broadcasting in all studied characters in both seasons. The interaction had significant effect on leaf area index, number of spikes/m² and grain yield which produced the highest values with using drilling method and application of 100 kg N/fed. and 80 kg N/fed., respectively in both seasons. It could be concluded that planting barley with drilling method and application of 80 kg N/fed. are the optimum for increasing barley production under the experimental site and the same conditions.

Key words: Barley, sowing method and nitrogen fertilizer.

SOIL CONSERVATION BY MODERN TILLAGE IMPLEMENTS**OLETI CHARAN CHOWDARY**

Agricultural machinery or tools which support conservation agriculture generally refers to cultivation system with minimum or zero tillage and in-situ management of crop residue. Farmers in developed countries used the different types of implements for conserving the agriculture such as zero till seed drill, root till seed drill, happy seeder, slit till drill and combine tillage machinery etc. Conventional tillage practices necessitate the use of heavy equipment that often causes soil compaction, impairs soil physical conditions and creates conditions leading to soil erosion. Many western countries, studying their conventional tillage systems through the new perspective of sustainable approaches to agriculture, are developing new tillage practices, called conservation tillage, which limit tillage to essential operations and prevent damage to soil. The majority of the small-scale farmers in developing countries use indigenous tillage systems. These are low-cost, locally adapted technologies that reflect considerable knowledge of sustainable agriculture. Conservation tillage, as compared to conventional practices has better performance in the term of increased benefits: cost ratio (2.0 - 2.5) and water operational energy (5 - 26%) .

DEVELOPING NEW GENOTYPES IN RICE WITH ENHANCED YIELD POTENTIAL, NUTRITIONAL PROPERTIES AND DISEASE RESISTANCE**¹OM PRAKASH RAIGAR*, ²DAISY BASANDRAI, ³BHALLAN SINGH SEKHON AND ⁴DINESH KUMAR**

^{1,2,4}*Department of Crop Improvement, CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) India, 176 062, ³Department of Vegetable Science & Floriculture, CSK Himachal Pradesh Krishi Vishvavidyalaya, Palampur (H.P.) India, 176 062*

Food insecurity coupled with malnutrition and hidden hunger is posing a great challenge to the scientists engaged in agriculture. This indicated the immense need to focus on developing nutrition rich cultivars/hybrids with high yield potential. Keeping this in view, the present study was undertaken for the improvement of Rice with respect to above mentioned aspects. Line x Tester analysis approach was used to develop nutrition rich, disease resistant and consumer acceptable hybrids. Basmati/ aromatic Rice with preferable grain length, desirable taste and high yield potential was used as female parent while Red rice was used as male parent to incorporate the high nutrition (Iron and Zinc content), medicinal properties and resistance to the leaf and neck blast diseases. For study, basmati/aromatic rice genotypes namely Pusa 1121, Sel, Kasturi, Super Basmati, PB 1509, HPR 2800, HPR 2373, HPR 2590, RYT 3178 and red rice genotypes namely HPR 2795, HPR 2720 were used as female and male parents, respectively. The crosses were attempted during 2017-18 at experimental farm, CSK HPKV, Rice and Wheat Research Centre, Malan (Kangra) H.P. and evaluation of hybrids will be done during *Kharif* season 2018 at Malan (Kangra). The material generated could acts as a boon to farmers by increasing the turnover in terms of yield, disease resistance and quality.

CONSERVATION OF AGRICULTURAL BIODIVERSITY AND SUSTAINABLE USE OF IN AGRICULTURE**OM PRAKASH YADAV^{1*}, A. K. RAZDAN¹, SURBHI KOHLI¹ AND KANHEYA LAL YADAV²**

1 Division of Plant Breeding & Genetics, Sher-e-Kashmir University of Agricultural Science and Technology, Chatha, Jammu-180009 (J&K) India, 2 Department of Floriculture and Landscaping, College of Horticulture and Forestry Jhalrapatan, Jhalawar-326023, Rajasthan (India)

Cultural diversity in remote mountain regions is closely linked to biodiversity, as there is a symbiotic relationship between habitats and cultures, and between ecosystems and cultural identity; indeed, religious rules and rituals often strengthen this relationship and are characterized by a conservation ethic. In order to allow the earth to continuously play its mother ship role and to enhance the biodiversity, man developed a body of laws and regulations known as taboos to regulate his relationship with his environment. Furthermore, he developed farming systems and fashioned farm tools, which helped him to sustain the biodiversity. Imposition of legislation to enhance the biodiversity is likely to worsen the predicament of the people. Therefore, contemporary biodiversity conservation needs to take into account alternative economic activities, which will relieve the land from the constant pressure it is being subjected today. The data collected are analyzed within the framework of traditional knowledge-based systems methodology, using the conservation purpose of rules and practices as a means of typifying the information on sacred natural sites (forests/groves, pastures, water bodies), on the phenomenon of dedicating forests to a deity, on the inherent taboos regarding resource exploitation, and on other traditional beliefs and customs, in order to understand the environmental and conservationist implications of these rules and practices. The meaning of the term conservation is itself controversial. We propose that to qualify as conservation, any action or practice must not only prevent or mitigate resource overharvesting or environmental damage, it must also be designed to do so. The conditions under which conservation will be adaptive are stringent, involving temporal discounting, economic demand, information feedback, and collective action. This knowledge and related conservation rules need to be strengthened in the face of current change.

RESPONSE OF DIFFERENT FERTILIZERS ON SOIL FERTILITY AND PRODUCTIVITY OF RICE (*ORYZASATIVA* L.) OMKAR SINGH¹ AND SHIVANGI²

¹Department of Soil Science and Agril. Chemistry / ²Department of Agronomy, S.V.P.U.A&T, Meerut, (U.P.) 250110

In order to study response of different fertilizer on soil fertility and productivity of Rice (*Oryza sativa* L.) a field experiment was conducted at Agronomy Research Farm of S.V.P.U.A.&T, Meerut (U.P.) during Kharif season 2018. The experiment consisted of six treatment such as T₁ (control), T₂ (RDF), T₃ (Soil test based recommendation), T₄ (Indo-Gulf Different Fertilizer), T₅ (TCL Different Fertilizer) and T₆ (Farmer's Practice). The soil of experimental field was silt loam texture, low in organic carbon (0.38%) and low in available nitrogen (151.76 kg ha⁻¹), phosphorus (14.75 kg ha⁻¹) and medium in potassium (248.0 kg ha⁻¹) and low in sulphur (9.00 kg ha⁻¹), zinc (0.50ppm) and boron (0.46ppm). All the growth parameters viz. plant height (cm), number of tillers (m⁻¹), and yield attributes like number of grains panicle⁻¹, test weight, grain and straw yield (q ha⁻¹), uptake of nitrogen, phosphorus, potassium, sulphur, zinc and boron were maximum under T₃ which was at par with T₄ and T₅ and significantly superior over T₁ (control), T₂ and T₆. The maximum grain yield of rice (46.64 q ha⁻¹) was recorded with T₃ which was significantly higher over than control (20.08 q ha⁻¹), T₆ (30.78 q ha⁻¹) and T₂ (38.10 q ha⁻¹) while at par with T₅ (43.92 q ha⁻¹) and T₄ (44.97 q ha⁻¹). The grain yield of rice was increased with the treatment T₃ 22.41% and 51.53% over T₂ and T₆ respectively. Similarly 3.71% and 6.19% over T₄ and T₅ respectively. The yield difference between both the different fertilizers was not upto the level of significance. Variation in availability of nutrients was observed under most of the treatments due to different nutrients management. The higher availability of nutrient was observed under all the treatments except control and farmer's practice. The availability of S, Zn and B were maintained under different fertilizers treatment and soil test based recommendation.

Key Words: *Oryza sativa*, soil fertility, organic carbon and growth parameters.

IMPROVEMENT IN INDIAN MUSTARD THROUGH HETEROSIS OMPAL¹, ARUN KUMAR², SHENDE R. T.² AND VIVEK RANA²

Department of Genetics and Plant Breeding¹ and Agricultural Biotechnology², Sardar Vallabh Bhai Patel University of Agriculture and Technology, Meerut-250110

Indian mustard (*Brassica juncea* L. Czern & Coss) is an important Rabi season natural amphidiploids (2n = 36) oilseed crop; belongs to family Cruciferae and genus Brassica. *B. juncea* is a predominantly self-fertilized crop with 5-15 cross-fertilization. Mustard seed is the world's second leading source of vegetable oil and protein meal after soybean. It is mainly grown in northern part of India, Rajasthan is the largest producing state followed by Uttar Pradesh. Heterosis breeding could be a potential alternative for substantially increasing the production of Indian mustard. Successful exploitation of heterosis would depend upon the identification of hybrids that are more productive than either of the parents and standard check cultivars and on the availability of suitable male sterility, fertility restorer systems. A number of cytoplasmic male sterility (CMS) systems have been described in *B. juncea*. Both heterosis (negative or positive) may be exploited for improvement in Indian mustard. Negative heterosis useful for days to 50 % flowering, Days to maturity, glucosinolates content and erucic acid content while positive heterosis for number of siliques per plant, number of seed per silique, grain yield, harvest index, 1000 grain weight and oil content etc. *Brassica juncea* constitutes 60-65% erucic acid of the total fatty acid. Feeding experiments with animals have demonstrated that rapeseed oil, rich in erucic acid, interferes in myocardial conductance and the peripheral vascular system, decrease survival time thus restricting their use as edible oil crop. Low erucic acid strains were initially identified for the first time in Canadian varieties of summer rape and summer turnip rape Later on, similar strains were identified in Indian mustard germplasm in Australia. Heterosis breeding scheme is better opportunity for produced genotypes with low erucic acid and glucosinolates and high grain yield.

Keywords- Mustard, Heterosis, Erucic acid and Glucosinolates.

VARIABILITY IN *SCLEROTINIA SCLEROTIORUM* OF MUSTARD IN NORTHERN REGION OF M.P. (INDIA)

TRENDS AND DECOMPOSITION ANALYSIS OF FOOD GRAIN PRODUCTION IN INDIA

OPMARUYA¹, OMPRAKASH VERMA² AND HEMANT KUMAR³

1. RSM College Dhampur, Bijnaur, Uttar Pradesh , 2. SS Sinha College, Jahanabad, Bihar; 3. Scientist ICAR-IIPR Kanpur, Uttar Pradesh

Food grain production in India has increased considerably from 50 million ton in 1951 to 252 MT by 2015-16. Introduction of green revolution, modernization of agriculture, encouragement to research and extension in agriculture are some of the factors contributed for this growth. The time series secondary data on area, production and yield of food grains from 1950-51 to 2015-16 were broadly partitioned into seven decades in order to demonstrate the trend of food grain production in more convincing and simple manner in the present study. The farmer could achieve these increasing mainly introduction to resistant varieties against different diseases and insects-pests, better management and matching with improved production and protection technologies. It has also been observed that the growth of area, production and yield for food grain registered positive during overall period. There is positive growth in area, production and yield during each of the decades, except negative growth rate in area during eighties and ninties. Decomposition analysis was performed and the percentage contribution of area, yield and their interaction on food grain production for each decades and the overall period was also estimated. The yield effect has a greater contribution food grains production as compared to area effect and combined area and yield interaction effect for overall period. There is area effect during fifties and sixties and after that production is changed due to mainly yield effect.

EFFECT OF MINERAL MIXTURE FEEDING ON MILK YIELD IN BUFFALO

P.K. MADKE, DEVENDRAPAL, SATYA PRAKASH & ANANT KUMAR

Krishi Vigyan Kendra, Muradnagar, Ghaziabad, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut

A field study was conducted in Ghaziabad District to observe the effect of mineral mixture feeding on milk yield in Buffalo. Animals were selected randomly from 5 villages of Ghaziabad (U.P.) (Muradnagar, Noorpur, Kanoja, Kusalia, and Badka). 20 Buffaloes were selected in their 2nd & 3rd stage of lactation and divided into two groups of 10 animals each. First group (T) was fed with 60 gm mineral mixture daily till 90 days of lactation. Other group (C) of 10 animals were not fed additional mineral mixture, which is farmers practice in that particular area. The farmers were not fed scientific method of feeding. They could not added proper quantity of mineral mixture in balance ration. To keeping in mind a trial was conducted in Ghaziabad District since 2016-17 (2017-18). Milk yield of these animals was recorded by their owners and these values were averaged for fortnightly interval. Milk production parameters like average daily milk yield, peak yield and total milk yield were compared between treatment and control groups. It was observed that average daily milk yield, peak yield and total milk yield were found significantly ($P < 0.05$) higher by 11.04, 12.37 & 11.07 in mineral mixture fed group than control group. On the basis of this, it is recommended that continuous feeding of mineral mixture bettered performance of milk yield in buffaloes.

MULTIVARIATE ANALYSIS OF GENETIC DIVERSITY IN CHRYSANTHEMUM GERMPLASM

PK MUHAMMED JASLAM, DEEPANKAR*, AJAY KUMAR

Department of Mathematics and Statistics, College of Basic Sciences and Humanities, CCS Haryana Agricultural University, Hisar-125004

Sustainable production of crops relies on germplasm improvement and genetic diversity. The use of multivariate techniques is an important strategy for germplasm classification and study of genetic relationships among genotypes. The data collected for 97 genotypes of chrysanthemum germplasm from All India Coordinated Research Project on Floriculture report 2016-17 (AICRP report 2016-17) were evaluated for eight quantitative traits through cluster and principal component analysis. The first three PCs with eigen values >1 contributed 83.01% of the variability amongst genotypes. The characters contributing more positively with PC1 were no of flower per plant, no of branches and flowering duration. The cluster analysis sequestrated 97 genotypes into 4 clusters based on between-group linkage method in which euclidean distance has been used as dissimilarity measure. The cluster III and IV were more clearly separated than cluster I and II. The cluster analysis revealed that considerable variation existed in few genotypes that could be implicated in selection of chrysanthemum for the development or improvement of cultivars and germplasm.

Keywords: Genetic Diversity, chrysanthemum germplasm, cluster analysis and principal component analysis

STUDIES ON DIRECT AND RESIDUAL EFFECT OF ORGANIC + INORGANIC SOURCES OF NITROGEN IN WHEAT (*TRITICUM AESTIVUM* L.) FORAGE COWPEA (*VIGNA UNGUICULATA* L.) CROPPING SYSTEM

P.K.SURYAWANSHI*, V.D.PAGAR¹, J.P.PATIL AND S.V.AHIRE

B. A. College of Agriculture, Anand Agricultural University, Anand (Guj.) 388 110, ¹ Dr. P.K.Suryawanshi, Asst Prof. HHSSMS College of Agriculture, Malegaon camp (Nashik) MH 423 105, ² Dr. V.D.Pagar, Asst Prof. HHSSMS College of Horticulture, Malegaon camp (Nashik) MH 423 105, ³ Prof. J.P.Patil, Asst Prof. HHSSMS College of Agriculture, Malegaon camp (Nashik) MH 423 105, ⁴ Asst Prof. S.V.Ahire, HHSSMS College of Agriculture, Malegaon camp (Nashik) MH 423 105

A field experiment was conducted during winter and summer season of 2011-12 and 2012-13 at college Agronomy Farm, B. A. College of Agriculture, Anand Agricultural University, Anand, Gujarat to study the Yield, Quality and nutrient status of soil under different integrated nitrogen management practices in wheat (*Triticum aestivum*) - forage cowpea (*Vigna unguiculata*) cropping sequence. The experiment was laid out in randomized block design with 21 treatments combination comprising of seven nitrogen management through chemical fertilizer and organic manures and three bio fertilizer inoculants. The experimental soil was sandy loam in texture and neutral in reaction with available N 199.5 kg ha⁻¹, P₂O₅ 32.17 kg ha⁻¹ and high K₂O of 389.00 kg ha⁻¹. Application of 75% RDN from chemical fertilizer + 25% RDN from FYM followed by 100% RDN from chemical fertilizer and 75% RDN from chemical fertilizer + 25% from Vermicompost produced significantly higher grain yield with Protein content in wheat. Significantly higher nutrient contents were recorded in the plots fertilized with 25% RDN from chemical fertilizer + 25% RDN from FYM + 25% RDN from Vermicompost + 25% RDN from castor cake followed by 50% RDN from chemical fertilizer + 25% vermicompost + 25% castor cake. Seed inoculation with *Azotobacter chroococcum* + *Azospirillum lipoferum* resulted in the higher grain yields and protein content in wheat. This treatment also showed higher available nitrogen, potassium and Phosphorus status of soil. Significantly higher green and dry fodder yield, and protein content in forage cowpea were recorded due to residual effect of combined seed inoculation with *Azotobacter chroococcum* + *Azospirillum lipoferum*. Application of 25% RDN chemical fertilizer + 25% from FYM + 25% from vermicompost + 25% from castor cake along with combined seed inoculation with *Azotobacter chroococcum* + *Azospirillum lipoferum* improved nutrient status of soil in wheat-forage cowpea sequence.

POPULARIZATION OF IMPROVED PRODUCTION TECHNOLOGIES IN GREENGRAM THROUGH FRONTLINE DEMONSTRATIONS

PSURYAVANSHI*, H KAUR AND Y SINGH

Krishi Vigyan Kendra, S.A.S. Nagar (Mohali), Guru Angad Dev Veterinary and Animal Sciences University, Ludhiana, Punjab

Green gram may be seen as one of the alternative crop to rice in *kharif* season in the pursuit of diversification and sustainability of rice-wheat cropping system in Punjab. Therefore, there is perceptible need to demonstrate the farmers latest improved technologies related to green gram production. The present study was conducted by Krishi Vigyan Kendra, S.A.S. Nagar during *kharif* season in 2017 with fifty three frontline demonstrations across twenty three villages of Mohali district. Improved and latest technology viz. Yellow Vein Mosaic (YVM) resistant varieties i.e. ML 2056 and MH 421, seed treatment with bio-fertilizer and fungicide, recommended seed rate, proper dose of fertilizers, herbicide application and plant protection measures were demonstrated. The results of demonstrations showed that farmers could increase the Green gram productivity notably by switching over to improved varieties and adoption of improved production technologies. Both the varieties (ML 2056 and MH 421) recorded higher yield (12.2 q/acre and 13.4 q/acre, respectively) than the farmer adopted variety (10.1 q/acre). The increase in the demonstration yield over farmer's practices was 20.8 per cent (ML 2056) and 32.6 per cent (MH 421). Net return and B:C ratio of demonstration plots were also higher than farmers practice.

Keywords: Green gram, Cluster Frontline Demonstrations, Improved Technologies, Yield, B:C ratio

EFFECT OF PHOSPHORUS AND ZINC FERTILIZATION ON THEIR AVAILABILITY AND PERFORMANCE OF GREEN GRAM (*VIGNA RADIATA* L. WILCZEK)

P. Angmo, Division of Soil Science and Agricultural Chemistry, SKUAST-Jammu

An investigation was carried out to study the "Effect of phosphorus and zinc fertilization on their availability and performance of green gram (*Vigna radiata* L. Wilczek)" at Research Farm of Division of Soil Science and Agricultural Chemistry, SKUAST-Jammu, Main campus, Chatha during summer season of 2015 with four levels of phosphorous (0, 20, 40 and 60 kg ha⁻¹) and four levels of zinc (0, 5, 10 and 15 kg ha⁻¹) with different treatment combination replicated thrice. The experiment was laid out in Factorial Randomized Block Design (F-RBD) using cv. SML-668 a high yielding variety of green gram as the test crop. The results of the investigation revealed that the effect of phosphorous and zinc on different growth and yield attributing parameters i.e. plant height at 20, 40 DAS and at maturity and plant population, number of pods per plant, 1000 seed weight, number of nodules per plant, seed yield and stover yield of green gram was found statistically significant. The grain yield (957.25 kg ha⁻¹) and stover yield (2399.40 kg ha⁻¹) of green gram were highest with the

combine application of P and Zn and found to increased with the successive application of phosphorous up to 60 kg ha⁻¹ and zinc up to 10 kg ha⁻¹ respectively and further increase in zinc levels found to decrease the growth and yield attributing trait, indicating antagonistic effect of P and Zn on each other as high P in soil reduce the uptake of Zn by roots. The interaction of P and Zn were also significant for all the growth and yield attributing parameters except plant population. The available phosphorous and zinc in soil were also significantly influenced and found to decrease with increase in time interval i.e. 20, 40 DAS and at maturity. So the application of 60 kg of P and 10 kg of Zn ha⁻¹ is best for optimum production of green gram (*cv.SML-668*) in the subtropical zone of Jammu which can be recommended for the farmers of the area for long term sustainable soil health.

CULTIVATION TECHNOLOGY OF PADDY STRAW MUSHROOM (*VOLVARIELLA VOLVACEA*) UNDER THE HILLY REGIMES OF DISTRICT EAST KAMENG ARUNACHAL PRADESH

P. P. TRIPATHI*, A. N. TRIPATHI AND A. K. SINGH*****

*Krishi Vigyan Kendra, East Kameng, Arunachal Pradesh, **Krishi Vigyan Kendra, Lower Subansiri, Arunachal Pradesh, ***Krishi Vigyan Kendra, Tirap, Arunachal Pradesh

Paddy straw mushroom (*Volvariella volvacea*) is a world famous edible mushroom variety that has high demand due to its deliciousness and nutritive value. It is also known as Chinese mushroom, ranks sixth among the cultivated mushrooms of the world having fast growth rate, easy cultivation technology and good acceptability at consumers' level. The high temperature requirement for its cultivation also makes it a good choice for mass scale adoption among the farming community. Beside a big demand of this mushroom in East Kameng district Arunachal Pradesh, there is no proper method of cultivation technology has been standardized till 2014. In this reference an experiment was conducted in five villages of District East Kameng (*Viz.* New Sopung, Jayanti, Pampoli, Wessang and Mebua) Arunachal Pradesh during the year 2014 to 2017. The said experiment was conducted in farmer's house to standardize the cultivation technology that would maintain above said environmental requirements. Paddy straw was used as main substrate materials for the cultivation. The average yield of paddy straw mushroom was found in the range of 650 to 800 gram / bundle/cutting and overall production 2.25kg to 3.0 kg after 3rd cutting. There were significant yield differences between different farmers sites were also observed during the experiment.

Key words: Paddy straw mushroom, cultivation technology, acceptability and consumers etc.

ICTS FOR NATURAL RESOURCE MANAGEMENT

P.SIVAMANOJNA¹ AND DEBASIS JAYAPURIA²

1: M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 2: Dept. of Ag. Extension, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Natural resource management is an interdisciplinary field of study that considers the handling of natural resources in physical, biological, economic and social aspects. It refers to the management of natural resources such as land, water, soil, plants and animals, with a particular focus on how management affects the quality of life for both present and future generations. In developing countries Information and communication technologies (ICTs) are helping to increase the efficiency, productivity, and sustainability of farms, providing up-to-date information on new farm technologies, access to credit as well as training, and the ability to interact with other farmers -often bridging the gap between scientific research and the farmer. Information Communication Technologies (ICTs) is the technology to facilitate and transfer of information across the different geographical location without taking much time and flow large volume of information. The information and communication technologies (ICTs) as tools to enhance the development of rural and remote regions remain in order to reach the unreached.. There are a growing number of tools and diagrams in the literature to capture the multiple dimensions of ICTs, and they all are providing enormous help in natural resource management. This will explore how ICTs help the farmers in natural resource management relevance to its status, opportunities, challenges and conclusions.

Keywords: ICTs, Natural resource management, sustainability.

SUSTAINABLE DEVELOPMENT

P. MANISHA

Advance Institute Of Science And Technology

Over the past few years, "Sustainable Development" (SD) has emerged as the latest development catchphrase. A wide range of nongovernmental as well as governmental organizations have embraced it as the new paradigm of development. A review of the literature that has sprung up around the concept of SD indicates, however, a lack of consistency in its interpretation. More important, while the all-encompassing nature of the concept gives it political strength, its current formulation by the mainstream of SD thinking contains significant weaknesses. These include an incomplete perception of the problems of poverty and environmental degradation, and confusion about the role of economic growth and about the concepts of sustainability and participation. How these weaknesses can lead to inadequacies and contradictions in policy making is demonstrated in the context of international trade, agriculture, and forestry. It

is suggested that if SD is to have a fundamental impact, politically expedient fuzziness will have to be given up in favor of intellectual clarity and rigor.

BIOLOGICAL CONTROL OF WEEDS: AN ECONOMICAL AND ENVIRONMENTALLY SENSITIVE WEED MANAGEMENT

PALAVALASANA VEEN KUMAR¹, JNANABHARATI PALAI² AND DEBASHIS NAYAK³

1: M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 2: Dept. of Agronomy, M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 3: Dept. of Agronomy, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Weeds can be defined as plants growing out of place. Biological weed control involves using living organisms, such as insects, nematodes, bacteria, or fungi, to reduce weed populations. In nature, plants are controlled biologically by naturally occurring organisms. Biological control research and implementation is even more relevant today. Foreign and native organisms that attack weeds are being evaluated for use as biological control agents. As a weed management method, biological control offers an environmentally friendly approach that complements conventional methods. It helps meet the need for new weed management strategies since some weeds have become resistant to certain herbicides. Biological control agents target specific weeds. Moreover, this technology is safe for applicators and consumers. Biological control of weeds will not eliminate the need to use chemical herbicides. Both of these tools need to be integrated with cultural practices, such as tillage and crop rotation, in the battle against weeds. By using Integrated Weed Management, the development of weeds that are resistant to biological or chemical agents can be slowed. A combination of control methods is generally required to best manage these nuisance plants. Biological control holds much promise for long-term, economical, and environmentally sensitive weed management.

Keywords: Weeds, Biological control and environment.

GLOBAL WARMING

PALLACHANDAN

Maya College

Global warming, the phenomenon of increasing the average air temperature near the surface of earth. The effects of global warming are environmental and social changes caused (directly or indirectly) by human. Few effects of global warming are melting of glaciers, early snow melt and severe droughts will cause more dramatic water storages. Raising sea levels will lead to coastal flooding. While many view the effects to be more substantial and more rapidly occurring than others, the scientific consensus on climatic changes related to global warming is rising then the average temperature of earth. The main cause of the current global warming trend is human expansion of "Green house effect". Gases that contribute to the green house effect are carbon dioxide, water vapor, nitrous oxide, methane. The new report includes a review of evidence that carbon dioxide from burning coal, gas, oil is heating the planet. It notes that some amount of irreversible climate disruption is already locked in, But things can also get much and much worse, additional global warming could wreak havoc across the globe, potentially leading to food shortages, the flooding of major cities etc., key points to be considered are sharp emissions cuts, which require massive technological push and is costly for us. Others include use of renewable energy, reduce water waste, using fuel efficient vehicles etc.

PARAMUTATION FOR EPIGENETIC CROP IMPROVEMENT

PALLAVI BHATT*, SALIL K. TEWARI, RANJANA TAMTA

*Department of Genetics and Plant Breeding, G. B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand, India-263145

Plant breeding relies on the pre-existing genetic diversity present within a species to develop allelic combinations that may provide desired traits. Paramutation describes a process that results in heritable epigenetic changes of gene regulation and trans-homologue interactions resulting in the discovery of epialleles i.e. alleles with identical DNA sequences but differing in DNA methylation and chromatin structure. These epialleles may provide for the epigenetic diversity resulting in additional sources of variation within a species that could be captured or created for crop improvement. Paramutation phenomenon encompasses the ability of the silenced allele (paramutagenic) to silence the other allele (paramutable) present in trans. The newly silenced (paramutated) allele remains stable in the next generations even in the absence of paramutagenic allele and acquires paramutagenic ability itself. The inheritance behaviour of these epialleles permits a fast diffusion of a particular phenotype in a population. Several classic evidences of paramutation have been found in plants like maize (pericarp color, p1), tomato (sulfurea), *snapdragon* (nivea) and transgenic crops (tobacco and petunia). Potential roles of paramutation through transgenerational transfer of epigenetic information have been proposed among which generating epiRIL (a homozygous line almost identical at the genetic level but segregates at the DNA methylation level) population has

revealed role of differentially methylated regions (DMRs) between accessions in influencing quantitative traits. Paramutation phenomenon leading to epigenetic variation and the stability of newly formed epigenetic variants over generations utilizes the potential of epigenetic variation to improve crops. The development and application of methods for widespread epigenome profiling and engineering may generate new avenues for using the full potential of paramutation in crop improvement.

IMPORTANCE OF BLACK SOYABEAN, POST HARVEST TECHNOLOGIES AND ITS BY-PRODUCTS- A REVIEW **PALMEI GAIBIMEI¹, ANUPAMA SINGH¹, N.C. SHAHI¹, ANIL KUMAR² & KHAN CHAND¹**

¹Department of Post-Harvest Process and Food Engineering, G. B. Pant University of Agriculture and Technology, Pantnagar-263145, Uttarakhand, ²Department of Food Science & Technology, G. B. Pant University of Agriculture and Technology, Pantnagar-263145, Uttarakhand

Soybean is one of the most important and consumed crop which provide complete protein with an affordable price. India being comprised of maximum vegetarian people sought protein in their everyday meal; soybean comes to picture by serving the purpose of replacing meat protein for people as whole. Soybean has different seed coat colours, including black, brown, red, green and yellow, the only difference between the black and the rest of the colours lies in the seed coat where the black soybean contain abundant anthocyanin pigments. Black soybean is also considered as the miracle crop due to its nutritional values and potentials to develop as healthy functional food ingredients. Black soybean provides many health beneficial effects such as anti-mutagenicity, anti-inflammatory properties, inhibition of low density lipoprotein oxidation and DNA damage reduction. Hence due to their various beneficial effects, black soybeans are increasingly seek in food and medicinal industries. There are many unit operations involved in post harvest handling and processing of black soybean to prevent losses and to maintain the quality of the crop. Some of them include harvesting, threshing, drying, cleaning, packaging, storage, transport, dehulling, cracking, etc. Black soybeans are used for producing wide variety of products such as soymilk, tofu, soy sauce, natto, tempeh, soy oil, soy flour, texturized soy protein, black soy hull extract (anthocyanin), soy protein isolate, soy protein concentrate, etc. This paper aims to renew and revive the potential of the forgotten or underutilised black soybean crop having many functional and nutritional benefits calls out the researchers for a diverse expansion of importance of the seed crop to widen its uses and application in many ways.

Keywords: Black soybean, nutritional composition, health benefits, soy products

THERMAL IMAGING AS A POTENTIAL ELEMENT OF INTEGRATED PEST MANAGEMENT IN INDIAN AGRICULTURE

PANDASHUBHAOM¹ AND RATHORE RAKESH²

1- Institute of Agri Business Management, SKRAU, Bikaner, 2- Institute of Agri Business Management, SKRAU, Bikaner

Thermal Imaging is a successful technology in the context of non-contact method of temperature measurement. Previously, this imaging system was successful in medical and military system and it has recently found successfully applicable to agriculture also. IPM is a sustainable approach to pest management, where all the methods are integrated together to check the pest population with minimum usage of pesticides. To support the successfulness of Integrated Pest Management, Thermal Imaging may be a potential element in identifying the density of pests and diseases. Using optical sensor technology is useful to identify foliar diseases like powdery mildew in barley, yellow rust in wheat, etc., but the thermal infrared radiation has the potentiality to identify not only the diseases but also its density and its associated pathogens with high spatial resolution. Pests like termites, rodents, etc can easily identified and checked. Thermal radiation is useful in weed management and it calculates the temperature of the leaves. Thermal imaging helps in identifying quality seeds by measuring its temperature. Water level of the plant as well as of the field can be measured by using thermal imaging. Though thermal imaging technology is a costly affair for now, in future with the research and development, the concept of thermal imaging can be implemented in agriculture. Though the cost of this technology seems to be more, the opportunity cost of this technology will replace the cost incurred by not using it. In near future the technology, which is going to rule agriculture, thermal Imaging will be a great example of new technology for a progressive agriculture. This paper reviews the need of thermal imaging to be an element of Integrated Pest Management in coming years for Indian agriculture.

ASSESSMENT OF GENOTYPIC VARIABILITY IN OATS (*AVENA SATIVA* L.) FOR FODDER QUALITY

PANKAJ, ATMAN POONIA & DR. D.S. PHOGAT

Department of Genetics & Plant Breeding, CCS Haryana Agricultural University, Hisar (Haryana)-125 004

Oat (*Avena sativa* L.) is an important cool season cereal crop grown all over the world. It belongs to the family *Poaceae* and ranks sixth in the world cereal production following wheat, rice, barley maize, and sorghum. Oats are used widely as feed for livestock (cattle, sheep,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

poultry and horses). Most of the farmers use oats as livestock feed with or without mixing with concentrate. Present experiment was conducted at Forage research area of Department of Genetics & Plant Breeding, CCS Haryana Agricultural University, Hisar during *rabi* 2017-18. Different germplasm accessions of oats were used in this study. Significant genetic variability was found in these genotypes for various morphological and quality traits. Among the test genotypes, some lines have high value of crude protein in grain and fodder. Various morphological parameters like plant height, leaf length, and leaf width were found positively correlated with fodder yield. These traits can be utilized as indirect selection criteria for fodder and seed yield. Based on the study, it was concluded that these germplasm lines can be utilized in breeding programmes for improvement in seed and fodder yield.

Key word: Oats, Genotypic variability, Fodder quality, Seed yield.

“STUDIES ON NEWER INSECTICIDES AND THEIR COMBINATIONS AGAINST GRAM POD BORER, *HELICOVERPA ARMIGERA* (HUBNER) IN CHICKPEA (*CICER ARIETINUM* L.)”

PANKAJ BATHAM AND DR. PANKAJ KUMAR

(Dept. Of Entomology) Ph.D Research Scholar, Svpuat, Meerut

The present investigation was carried out during *Rabi* Season, 2017-18 at Student's Instructional farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) to study the newer insecticides and their combinations against gram pod borer, *Helicoverpa armigera* (Hubner) in chickpea (*Cicer arietinum* L.). The insecticides and their combinations tested were: Rynaxypyr 20 SC (18 g a. i./ha), 2% urea + Rynaxypyr 20 SC (18 g a. i./ha), Emamectin benzoate 5 SG (11 g a. i./ha), 2% urea + Emamectin benzoate 5 SG (11 g a. i./ha), Flubendiamide 480 SC (60 g a. i./ha), 2% urea + Flubendiamide 480 SC (60 g a. i./ha), 2% urea and compared with control (water spray). Rynaxypyr 20 SC (18 g a. i./ha) was found most effective insecticide with 100% reduction in larval population, followed by flubendiamide 480 SC @ 60 g a.i./ha with 92.30 % and Emamectin benzoate 5 SG@11 g a.i./ha with 84.61 % reduction in larval population. Least effective treatment was 2% Urea in which only 76.92 % reduction in larval population was found. All treatments were found effective over control that gave significantly higher yield of chickpea. This study recommends the use of Rynaxypyr 20 SC for the control of gram pod borer.

Key words: Rynaxypyr, flubendiamide, Emamectin benzoate, gram pod borer, *Helicoverpa armigera*

EFFECT OF ORGANIC FARMING ON SOIL PHYSICAL PROPERTIES

PANKAJ CHAURASIYA, AKASH KUMAR, LAXMAN KUMAWAT AND SATENDRA KUMAR

“Department of Soil Science & Agricultural Chemistry”, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut 250110

Organic farming could be an option to ensure food, air, water, and soil quality leaving the environment safe for the present and future generation. The effects of organic farming practices on the development of soil physical properties, and in particular, soil structure in comparison with conventional agricultural management. Organic farming is a production system, which avoids the use of synthetic fertilizers, pesticides, growth regulators, and additives and relies on natural principles that contribute to the growth, development, and health of plants. Its aim is safe production of quality produce and maintenance and improvement of the sanitary condition and quality of soil and the environment. Soil structure is most important among the physical soil properties due to its large impact on the water, air and thermal status, chemical and biological properties of the soil, soil tilth and the growth of plant roots are affected by farming system. It is an indicator of soil fertility and productivity. The objective of this study was to determine the contribution of organic agriculture to soil structure improvement by comparing soil structure indicators from organic farms.

Key Words: Soil structure, soil quality, organic management and biological properties etc.

BIO FERTILIZERS, A POTENTIAL TOOL FOR SUSTAINABLE SOIL HEALTH AND NUTRIENT

PANKAJ KUMAR* AND ROHTAS KUMAR

Department of Soil Science, CCS Haryana Agricultural University, Hisar-125004

Dependence on chemicals for future agricultural needs would result in further loss in soil health, possibilities of water contamination and calculated burden on the fiscal system. Indiscriminate synthetic fertilizer usage has polluted the soil, water basins, destroyed micro-organisms and eco-friendly insects, made the crop more susceptible to diseases and depleted soil fertility at the primary levels as of today, which is the main concern of the write up. In this critical context, Microorganisms have been emerged as the potential alternative for the productivity, reliability and sustainability of the global food chain. Carrier based bio fertilizers have already proved to be the best over the agro chemicals and have been showing the tremendous effect on the global agriculture productivity since the past two decades.

Rectifying the disadvantages of the carrier based bio fertilizers, liquid bio fertilizers have been developed which would be the only alternative for the cost effective sustainable agriculture. The increasing productivity by applying excessive fertilizers and pesticides has led to various environmental problems such as contamination of water resources, loss of soil fertility, and hazard to human health disorders etc. There is a need for more sustainable way of producing crops relies organic farming and minimized use of harmful chemicals. One best alternative is to supplement synthetic chemicals with useful microorganisms such as Plant Growth Promoting Rhizobacteria (PGPR), Mycorrhiza, Blue green algae, etc. Bio fertilizers and bio pesticides affect plant's growth and development, change nutrient dynamics and alter a plant's susceptibility to disease and abiotic stress.

FARMERS' PERCEPTIONS TOWARDS APPLICATIONS OF MODERN FARMING TOOLS USED IN VEGETABLE PRODUCTION AT SOLAN DISTRICT, HIMACHAL PRADESH-INDIA

PANKAJ THAKUR*, PIYUSH MEHTA, KRISHAN KUMAR AND GAURAV

Department of Business Management, Dr. Y. S. Parmar University of Horticulture and Forestry, Nauni-Solan, Himachal Pradesh (173230), India

Increase in vegetable productivity has been achieved in several parts of the country mainly by modernizing agriculture. In this context application of modern farming tools play significant role. The concerned study has analyzed the awareness levels of farmers' towards application of modern farming tools used in vegetable production and study the effect of modern farming tools on farmers' income. The scientific orientation inclined by farming community that new methods of farming give better results to a farmer than old tools. The key economic motivation that enforced the farming community were that farmer should work towards higher yield and economic profits. The key constraints and problems emerged during the study mainly circumvented around the lack of sufficient incentives provided by the government and the imparting of adequate training for the use of farm tools.

Keywords: Perception, Modern farming tools, Vegetable Production.

WATER MANAGEMENT OF HORTICULTURAL CROPS IN DRY REGIONS

PANKAJ

Department of Horticulture (Floriculture and Landscape Architecture), CCS Haryana Agricultural University, Hisar (125004) Haryana, India

There is a fundamental role of water in agriculture and anybody planning to set out as a farmer must consider the availability of water resource near the place where he intends to put up the farm. Water is very important both for livestock and for plants. It forms a large part of tissues and cells. Due to increase in population there is also an increase in demand of fresh water. And the water resources are degraded to large extent. Ground water level is also dropping at the rates faster than ever. Water is one of the most important plant growth regulator and how we manage it will influence our future well being. Agriculture sector is the largest user of water i.e. >70%. In agriculture water is used for irrigating the fields, for diluting the insecticides and herbicides. Increase in water demand and water scarcities will have a major economic and political impacts. As the horticultural crops have high value and intense cultural practices they are better suited for adaptation to improve water saving technologies than many agronomic crops. Not only the arid regions but other regions with saline water are suffering from the water scarcity. The productivity of dry regions is less due to unavailability of irrigation water. But water can be used with maximum efficiency by using drip irrigation system. Recently drip irrigation system is used for many vegetable in southern and eastern United States. Micro irrigation have also been used successfully in fruit trees. Horticultural crops have higher market value than traditional agricultural crops. Hence, improved water saving technologies have been focused on certain horticultural crops.

Key words : Water management, horticultural crops, dry region etc.

RECENT ADVANCES IN MUTATION BREEDING OF FRUIT CROPS

PARAMJEET SAJWAN* AND HEERENDRA PRASAD

Yashwant Singh Parmar University of Horticulture and Forestry, Nauni Solan HP 173230

A wide range of genetic variability has been induced by physical and chemical mutagens. In the past several decades, induced mutations have contributed immensely to the development of improved varieties in several crop plants. Till date, 3,218 mutant varieties have been released worldwide. More than 60 % of officially released mutant varieties are from Asia with China, India and Japan topping the list. Optimum utilization of mutant lines worldwide can be made by free exchange of a mutant material and its deployment in regions where a farmers' need is paramount. With the aid of well-defined objectives in national research programmes, availability of efficient mutagenesis protocols and high-throughput, efficient phenotype screening methods, mutagenesis can be made more useful in the improvement of crop plants. Mutant identification selection at the genotypic level, using new, high-throughput technologies, has changed the way mutations are now used in genetics and breeding. The possibility of directed mutation by using mutagens and certain chemical

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

pretreatments should help in achieving the goal. Induced mutations are poised to play a more significant role in the times to come.

Keywords: Fruit Crops, Mutagenesis, Mutation Breeding

HORTICULTURE - THE GROWTH DRIVER OF AGRICULTURE: CHALLENGES AND OPPORTUNITIES

PARDEEPSINGH¹, M K VAIDYA², ANKITA³, KAPIL DEV⁴

Department of Social Sciences, Yashwant Singh Parmar University of Horticulture and Forestry, Nauni, Solan (H.P.) - 173230

Although agriculture occupies shrinking share of India's national economy, but achieving rapid growth in agriculture remains policy concern nationwide. The contribution of agriculture to India's GDP fell from 40 per cent in 1980-81 to 21 per cent in 2004-05 and 17.01 per cent in 2015-16. However 72 per cent of population lives in rural areas and 3/4th still depends on agriculture for livelihood. Since the 1980s, the international trade in fruits and vegetables has expanded rapidly. There is an overall increase in the demand for fruits and vegetables for consumption both in the fresh and the processed form. The study conducted on area, production and productivity of horticultural crop was found that compound annual growth rate using data from 2001 to 2016 and it was found that there was 2.77 per cent increase in area under horticulture crop, 5.53 per cent increase in production and 2.69 per cent increase in productivity. Data collected from Horticulture Statistic division Department of agriculture cooperation and farmers welfare of different horticulture crop viz. fruit, vegetables, flower, spices, medicinal and aromatic plantation show there was compound growth rate of 2.47 per cent of area and 5.35 per cent in production. Data collected from on change cropping pattern among the farmers of Himachal Pradesh and it shows that they are shifting to horticulture at the rate of 2.47 per cent. Data collected from Government of India shows that there was significant increase in horticulture export i.e., 13.33 per cent and import is 19.30 per cent. when comparing the export of field crop, horticulture and livestock the results are obtained which shows that the compound annual growth rate were 19.83 per cent, 13.33 per cent and 17.16 per cent respectively and import of field crop, horticulture and livestock the results are obtained which shows that the compound annual growth rate were 26.41 per cent, 19.30 per cent and 17.87 per cent respectively. Though there is significant increase in area production and productivity of horticultural crop over years but data on export and import shows that farmers are facing challenges that are making balance of trade negative thus we need to combat those problems.

Key words: Agriculture, growth rate, export and import, demand.

EFFECT OF FLAXSEED POWDER SUPPLEMENTATION ON THE HAEMATOLOGICAL AND SERUM BIOCHEMICAL PROFILES OF GIRIRAJA BIRDS

PARESH BOTLE¹, B.G. DESAI¹, SHALU KUMAR^{1*}, J.S. DHEKALE², PRADNYA SHIGWAN¹, A. J. MAYEKAR¹ AND N.N. PRASADE¹

¹Department of Animal Husbandry and Dairy Science, Dr. B.S. Konkan Krishi Vidyapeeth (Agricultural University), Dapoli, Dist. Ratnagiri, Maharashtra, INDIA, ²Department of Agril. Economics and Statistics, Dr. B.S. Konkan Krishi Vidyapeeth (Agricultural University), Dapoli, Dist. Ratnagiri, Maharashtra, INDIA

The experiment was conducted at Department of Animal Husbandry and Dairy Science, Dr. B.S. Konkan Krishi Vidyapeeth, Dapoli, Dist. Ratnagiri, Maharashtra to determine flaxseed powder supplementation on the haemato-biochemical parameters of Giriraja birds. A total of 140 one-day-old Giriraja chicks were individually weighed and randomly assigned to five treatment groups, each with 4 replicate pens of 28 chicks. The dietary treatments included were T₀: Control (basal ration), T₁: basal ration + 2 per cent flaxseed powder, T₂: basal ration + 3 per cent flaxseed powder, T₃: basal ration + 4 per cent flaxseed powder and T₄: basal ration + 5 per cent flaxseed powder. The results of the experiment revealed that incorporation of 5 per cent flaxseed powder in Giriraja bird as feed additive significantly improved haematological parameters viz. Hb (8.60 mg/dl), RBC (2.501 10⁶/mm³), WBC (22165.5cell/mm³) and PCV (32.35 %) and biochemical traits i.e. Cholesterol (93.92 mg/dl), HDL (53.50 mg/dl), LDL (42.57 mg/dl), VLDL (19.11 mg/dl) and Triglycerides (95.50 mg/dl) as compared with control group. The study concluded that 5.0 per cent of flaxseed powder more beneficial for maintaining blood haematological and serum Biochemical profile. Therefore, it may be recommended that incorporation of flaxseed powder in the basal diet of Giriraja birds improved their physiological status.

Keywords: Flaxseed Powder, Haematological and biochemical profile, Giriraja

STUDY OF PPD-D1 GENE IMPACT ON DIFFERENT PHENOTYPIC TRAITS IN WHEAT (*TRITICUM AESTIVUM* L.)

PARGAT SINGH^{*1}, V. K. MISHRA¹, BRAJESH SINHA¹, SHWETA SINGH²

¹ Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005, ² Department of Botany, Institute of Science, Banaras Hindu University, Varanasi-221005

Wheat is world's most widely cultivated food crop which belongs to the family Graminae (Poaceae) and the genus *Triticum*. It is the most important food grain in the world that ranks second in total production as a cereal crop, after maize and ahead of rice. The winter wheat

and spring wheat varieties can be photoperiod sensitive or insensitive. The photoperiod insensitive wheat varieties are early to flowering in short days condition as compared to their counterpart photoperiod sensitive varieties. Photoperiod sensitivity is controlled by Ppd-A1, Ppd-B1 and Ppd-D1 genes of group 2 chromosomes. Ppd-D1 gene has been identified as the major source of earliness in wheat varieties worldwide that Ppd-D1 allele is expressed to synthesize PRR protein and thereby cause induction of the Vrn-3 florigen, under SD and LD conditions. All the 242 lines of wheat were genotyped with Ppd-D1 marker and observed 1:1 segregation among the population for the presence and absence of this gene. It was observed that presence of this gene reduced 11 traits as compared with those lines which had no Ppd-D1 gene but few traits were expressed positively by the presence of this gene. Reduction in days to heading and plant height is the common effect observed by many researchers and days to heading also affect the spot blotch severity as reflected by area under disease in this experiment. Diversity in climate is attribute of India and variability created by Ppd-D1 gene for flowering time may be exploited in breeding programme for development of varieties for divergent regions.

Key words: wheat, Ppd-D1 gene, photoperiod sensitivity

MICROBIAL DECOMPOSITION OF CROP RESIDUES

PARMAR PRATIK MANSUKHBHAI*

Department of Agronomy, College of Agriculture, Junagadh Agricultural University, Junagadh, Gujarat.

Whatever remains after something else has been taken, separated, removed, called residues. Crop residues are Organic residues remaining after the harvesting and processing of a crop like stalks, stems, leaves, roots, etc. Nowadays management of Crop residue is important as it is highly considered as major factor in organic and conservation agriculture. There are different practices for crop residue management, among them burning is not considered as eco-friendly because it causes pollution and nutrient losses. While other practices like mulching, in-situ incorporation and composting are eco-friendly, but it takes time if proper environment for recycling is not available. Composting and In-situ incorporation method require better physical chemical and microbial condition for the decomposition of crop residues. Soil physical and chemical properties decide the rate of microbial activity in case of In-situ incorporation while in composting its affected by the environment created by us for microbial decomposition. Therefore, favourable environment for microbial activity is necessary which is very important for microbial decomposition of crop residues. There are two types of crop residues available first one is residues remained on field and another one is processed crop residues. Burning, mulching, in-situ incorporation and composting are four different practices for their management. Rice stalk, wheat straw, sugarcane trash, sorghum and maize stubbles are major crop residues available. Their chemical structure consist of cellulose, hemicellulose, polysaccharides, starch, protein, pectin and chitin. Their microbial degradation through in-situ incorporation and composting can be done properly and in eco-friendly manner.

Key words: crop residues, pollution, in-situ incorporation, composting, microbial activity, microbial decomposition, chemical structure.

EFFECT OF WATER STRESS ON PHYSIOLOGICAL CHARACTERS OF CERTAIN VARIETIES OF RICE (*ORYZA SATIVA* L.).

PARVEEN FATIMA¹, ANURAG MISHRA² AND PUSHPENDRA KUMAR^{1*}

¹Department of Agricultural Biotechnology, ²Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut-250110, U.P., India. Division of Genetics, IARI, New Delhi

Water stress is the major problem for the rice production in several regions of the world. It directly affects growth of rice, especially in low rainfall season. For the better understanding of water stress effect in certain resistant and susceptible rice varieties during *Kharif* season of 2014-2015 and 2015-2016 experiment was conducted under rainout shelter. A total four basmati rice varieties namely; PusaBasmati1, Pusa1121, Type3 and Vallabh Basmati 21 and two non-basmati Nagina 22 and Susk Samrat were studied for physiological parameters under water stress. Water stress affected the rate of photosynthesis, relative water content and also membrane stability index. The Photosynthesis ranged from 6.58 $\mu\text{mol.m}^{-2}\text{s}^{-1}$ (VB21) to 9.85 $\mu\text{mol.m}^{-2}\text{s}^{-1}$ (Nagina 22) with an average mean of 7.8 $\mu\text{mol.m}^{-2}\text{s}^{-1}$ under control condition, while under water stress condition Photosynthesis ranged from 3.09 $\mu\text{mol.m}^{-2}\text{s}^{-1}$ (Vallabh Basmati 21) to 7.21 $\mu\text{mol.m}^{-2}\text{s}^{-1}$ (Nagina 22) with an average mean of 4.69 $\mu\text{mol.m}^{-2}\text{s}^{-1}$. The Membrane stability index ranged from 40.81% (Type3) to 48.23% (PB1121) with an average mean of 43.92 % in control condition, while under water stress condition membrane stability index ranged from 33.44 % (Type3) to 44.41% (Nagina 22) with an average mean of 33.74%. The Relative water content ranged from 61.38% (PB1121) to 77.79% (PusaBasmati1) with an average mean of 69.59% in control condition, while under water stress condition relative water content ranged from 34.57 % (PusaBasmati1) to 58.98% (Nagina 22) with an average mean of 46.44%. Water stress affected the growth and reduced the fresh shoot and root weights, root and shoot lengths and the photosynthetic pigments which ultimately reduced the photosynthetic rate and physiology processes. The water stress has more adverse effect in the basmati rice varieties in comparison to non-basmati rice varieties Nagina 22 and susk samrat also known as water stress rice varieties.

Keywords: Rice, Water stress, Photosynthesis, Relative water content, Membrane stability index.

NATURAL RESOURCE MANAGEMENT AND ITS CONSERVATIONS**PAWAN K NAGAR¹, J PRATHORE² AND ANKITA MANTRI³***¹Department of Horticulture, BACA, Anand Agricultural University, Anand, Gujarat, ²Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K), ³Department of Fruit Science, ASPEE CHF, Navsari Agricultural University, Navsari Gujarat*

Natural resource management refers to the management of **natural resources** such as **land, water, soil, plants** and **animals**, with a particular focus on how management affects the **quality of life** for both present and future generations. Natural resource management deals with managing the way in which people and natural **landscapes** interact. It brings together land use planning, water management, **biodiversity conservation**, and the future sustainability of industries like **agriculture, mining, tourism, fisheries** and **forestry**. It recognises that people and their livelihoods rely on the health and productivity of our landscapes, and their actions as stewards of the land play a critical role in maintaining this health and productivity. Natural resource management specifically focuses on a scientific and technical understanding of resources and **ecology** and the life-supporting capacity of those resources. **Environmental management** is also similar to natural resource management. In academic contexts, the **sociology of natural resources** is closely related to, but distinct from, natural resource management. The success of natural resource management is ultimately determined by the level of community involvement and the adoption of ecologically sustainable practices across the community. It integrates the management of social, economic and environmental values by involving the community and industry in planning and decision making. Conservation of natural resources includes developing location specific, cost effective, eco-friendly conservation and management technologies for higher input use efficiency, agricultural productivity & profitability without deteriorating natural resource base.

DOUBLING THE FARMER INCOME THROUGH HI-TECH HORTICULTURE**PAWAN K. NAGAR, J PRATHORE¹ AND AMIT KUMAR¹***Department of Horticulture, BACA, Anand Agricultural University, Anand-388 110, ¹Division of Fruit Science, FOH, SKUAST-Kashmir, Shalimar Campus, Srinagar (J & K)*

Precision farming in Horticulture sector provides an excellent opportunity in raising the income of the farmers throughout the year. A significant shift towards horticulture is envisaged in the country with an increase in area and production after the launch of the RKVY scheme. Despite the scope and importance for cultivation of various horticulture crops, the sector is yet to make break-through in the productivity fronts and market chain for many reasons. This is because of the fact that the farmer in mass are not adopting the latest production technologies comprising of precision horticulture practices related to soil, water and selection of planting material. The adoption of precision horticulture technologies in protected cultivation there by help in doubling the farm income. This precisely envisages less challenges and more profit by using per drop of water. There were more common challenges in crop production mainly decrease in water level in bore wells reaching up to 1000 feet depth, less or poor availability of supply of electricity to operate the pumping of water, non-judicious use of inputs and low market prices resulted in lesser productivity with low income. The private company partners were also involved particularly in Colour and Green Capsicum, Carnation and English Cucumber to give technical information to the farmers on management of crop under polyhouses and marketing avenues. The impact of interventions helped in doubling the income of the farmers through hi-tech horticulture from zero knowledge level in polyhouse cultivation. The benefit was also extended to the farmers by assisting with subsidies from the department through RKVY, NHM and KrishiBhagya schemes for construction and cultivation of crops in polyhouses. Local employment was generated through this activity as the polyhouse operations require labor daily at an average of 5 person days per polyhouse. Thus, the increase in the income by these farmers helped in gaining confidence in precision farming technologies.

KNOWLEDGE LEVEL OF CITRUS GROWERS IN HARYANA**PAWAN KUMAR*, P. S. SHEHRAWAT AND J. S. MALIK***Department of Extension Education, CCS Haryana Agricultural University, Hisar*

The study was conducted to study the knowledge levels of different citrus growing farmers in Haryana. Being one of the most widely grown commercial fruit crop in Haryana the crop is getting popularized day by day and hence an increase in area under cultivation and production is witnessed in recent past. The study revealed that majority of the mausambi growers (83.33 per cent) had significantly higher knowledge level whereas, 16.67 per cent had medium level of knowledge regarding time of planting. Similarly, 83.33 per cent of the respondents possessed high level of knowledge about irrigation techniques whereas; only 4.17 per cent of the respondents had low level of knowledge. Further, it was revealed that maximum number of mausambi growers (75.00 per cent) possessed high level knowledge regarding recommended cultivars while only 25.00 per cent growers possessed medium level of knowledge. In regard to manure and fertilizers, it was recorded that only 14.17 per cent of respondents had medium knowledge whereas 75.00 per cent growers had high level of knowledge. It was also recorded that majority of the respondents (75.00 per cent) had high knowledge level regarding

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

intercultural operations. Hence, it can be delineated that majority of the citrus growers in Haryana have good level of knowledge regarding different cultivation practice such as time of irrigation, proper manuring and fertilizer application, weed and pest control etc.

Keywords: mausambi, cultivation practices, knowledge level and Haryana

TO STUDY THE EFFECT OF SEED RATE AND ROW SPACING ON PLANT HEIGHT AT MATURITY OF FENUGREEK (*TRIGONELLA FOENUM-GRAECUM* L.)

PAWAN KUMAR¹, S.K. PHOR², S.K. TEHLAN³

Department of vegetable Science, CCS, Haryana Agricultural University, Hisar-125004

The experiment was carried out to find the effect of seed rate and row spacing on quality seed production of fenugreek (*Trigonella foenum-graecum* L.) was conducted at Research Farm of Department of Vegetable Science, CCS Haryana Agricultural University, Hisar during winter season of 2016-17. The seed material used for the experiment was a released variety *Hisar Sonali*. The investigation comprising of five different seed rate (16, 18, 20, 22 and 24 kg/ha) and three row spacing (20, 30 and 40 cm) was laid out in a factorial randomized block design with three replications with a plot size of 2.4 x 4.0 m. The result revealed that highest value for plant height (99.63 cm) was registered with a treatment combination S₅R₁ i.e. seed rate 24 kg/ha and row spacing 20cm.

Key words: Fenugreek, seed rate, row spacing, seed yield

STUDY OF BLACK POINT DISEASE OF WHEAT (*TRITICUM AESTIVUM* L.)

PAWAN SINGH, B.P. CHOUDHARY, LALTA PRASAD MISHRA, SIDDHARATH RAJAN, VIJAY KUMAR

Department of Plant Pathology, NDUAT- Kumarganj, Faizabad -224229 (U.P.)

Black point caused by various fungal pathogen each considered as minor disease, affected the grain as well as seed quality but its importance in global context can be imagined with the fact the U.S. grain standard to be damaged and only 2 percent are permitted in wheat grade as U.S. No.2. The disease is responsible for reduce market price and dockage by the elevator. Keeping in view, the above facts the present investigation on studies on black point disease of wheat was conducted with the objective of evaluation of wheat genotypes against foliar blight and its correlation with the black point infection. The monitoring of the disease in seed samples collected from different sources and locations. The maximum (1.15%) seed infection of the black point was recorded in PBW 154 which was collected from Bhudna village of the district Sitapur. Besides, the infected seeds were separated and classified on the basis of symptoms on grains. The fungal flora associated with various types of infected grains was isolated through standard blotter technique/PDA. The healthy and infected seed lot of respective varieties were analysed for germination which was affected by (9.56%), root length (1.26%), shoot length (0.96%), seedling dry weight by 0.5%, vigour index 69.1%, over the varieties.

The total fungal count on average basis over the variety was 8.11 and fungal flora isolated from infected seed included *Fusarium moniliforme*, *Bipolaris sorokiniana*, *Curvularia lunata*, *Alternaria alternate* and *Aspergillus species*.

ROLE OF HOST PLANT RESISTANT IN IPM

PAWAN SINGH, BHARTENDU YADAV, VIJAY KUMAR, SURYA PRATAP SINGH, RAVINDRA NATH NISHAD

Department OF Plant Pathology, NDUAT&T, Kumarganj Faizabad - 224229 (U.P.)

There are two type of resistant one is ecological resistant and other one is genetic resistant in ecological resistant. Apparent resistance resulting from transitory characters in potentially susceptible host plants due to environmental conditions and in genetic resistant when resistant is govern by a gene or modified in gene. Painter (1951) grouped mechanisms of resistance into 3 main categories viz. Non-preference, Antibiosis and Tolerance. Kogan and Ortman (1978) proposed term "Antixenosis" to describe the host plant properties responsible for non-preference. The 3 important mechanisms of resistance are Antixenosis, Antibiosis and Tolerance. Principles of Host Plant Selection - It is a process by which an insect detects a resource-furnishing plant, within an environment of a multitude of diversified plant species. (Panda and Khush, 1995) Generally, 5 phases are defined in this process (Kogan, 1994; Panda and Khush, 1995; Metcalf, 1999). Host-habitat finding, Host finding, Host recognition, Host acceptance and Host suitability. Concept of Biotypes- The term biotype is generally used to describe a population capable of damaging and surviving on plants previously known to be resistant to other populations of the same species. (Kogan, 1994). Host Plant Resistance in IPM Selection and growing of a resistant variety minimize cost on all other pest management activities. Advantages of HPR as a component in IPM-Specificity, Cumulative effect, Eco-friendly, easily adoptable. Effectiveness, Compatibility, Decreased pesticide application, Persistence, Unique situations.

DETECTION OF PLANT PATHOGENIC BACTERIA

PAWAN SINGH, SIDDHARTH RAJAN, SATYENDRA KUMAR VISHWAKARMA, ASHWANI PATEL

Department of plant pathology, NDUAT-Kumarganj, Faizabad (224229) U.P.

Gram staining test can differentiate bacteria into two broad groups that are Gram positive and Gram negative. Gram positive strain gives

Blue violet colour and gram negative strain give pink red to red colour. Dome test is modified test to that of indicator plant test where the healthy plant parts are vacuum infiltrated with infiltrated water extracts to test sample. This infiltrated plant parts are grown under high relative humidity. Immunoassay test involved the detection of antigen by antibody and the intensity of color resulting from enzymatic activity substrate determined through spectrophotometer or calorimeter. Immune florescent technique is important serological test when antibodies conjugated to a florescent dye, binds to bacteria may be visualized under immune fluorescence microscope. ELISA is one of the commonly used serological tests for the detection of seed borne bacteria. ELISA test is substrate beings to turn color due to presence of enzymes and even very low bacteria titers are detectable. RFLP is one of the advanced techniques adapted to plant science. The technique monitories variations in the strains and genera by monitoring changes in the length of defined DNA fragment produced by the digestion of DNA sample with restriction enzyme and therefore termed as restriction fragment length polymorphism. PCR provides a simple, denous method to exponentially amplified specific DNA sequence in vitro DNA synthesis. Overall for the detection of bacteria pathogens the process is initiated starting from simple and traditional method to the most recent to molecular one providing reproducible result. Also the method should be quick, cheap, and easy for comparable result without any ambiguity.

STUDIES ON REPRODUCTIVE TRAITS OF RED SINDHI CATTLE MAINTAINED AT A.C. DHULE

PAWAR J. N., *TADAVI F. R., GAIKWAD U.S. AND U. Y. BHOITE

Division of Animal Husbandry and Dairy Science, College of Agriculture, Dhule, Maharashtra

The data on reproductive traits of Red Sindhi cattle maintained at Division of Animal Husbandry and Dairy Science, College of Agriculture, Dhule, Maharashtra were collected and analyzed by least squares technique (Harvey, 1990) to estimate the effect of period of calving/birth, season of calving/birth, lactation order and age at first calving. Wherever the effects were significant, mean values were compared by Duncan's Multiple Range Test (DMRT) as modified by Kramer (1957). The correlations among the reproductive traits under study were also studied. The overall least squares mean for AFC, SP, LL, and CI was 1315.02 ± 14.30 days, 85.60 ± 13.36 days, 303.207 ± 11.85 days and 375.67 ± 14.35 days, respectively in Red Sindhi. The effect season of birth on AFC was significant ($P < 0.01$) and effect of season of calving on SP, LL and CI was non-significant. The influence of period of birth on AFC was significant ($P < 0.01$) and effect of period of calving on SP, LL and CI was non-significant. The variations due to lactation order and age at first calving group on SP, LL and CI was non-significant. Phenotypic correlation of LL and AFC was negative and non-significant (-0.089) and it was positive and significant ($P < 0.01$) LL with SP (0.60), LL with CI (0.76) and SP with CI (0.79) While, it was positive and non-significant of SP with AFC (0.06) and CI with AFC (0.04).

DOUBLING FARMER'S INCOME THROUGH INNOVATIVE APPROACH

PEBBETI CHANDANA AND KANCHETI MRUNALINI

Department of Agronomy, Professor Jayashankar Telangana State Agricultural University, Rajendranagar, Telangana

Doubling agricultural income in India is a gigantic task and the need of the hour in present day. The past strategies for development of agriculture sector in India have focused primarily on raising agricultural output and improving food security. The net result has made India not only food self-sufficient, but also a net food exporting country. But, the strategy did not clearly address the need to raise farmer's income, which is evident from the incidence of poverty among farm households. In this backdrop, the goal set to double farmer's income is central to promote farmers welfare, reduce agrarian distress and bring parity between income of farmers and those working in non-agricultural professions. There are three primary ways in which income of farmers may be enhanced viz., increasing the gross income, reducing the costs, and stabilizing the income. Some of the innovative approaches for doubling farmer's income are enhancing production through improved seeds, planting material and organic farming; adopting biotechnological approaches; genome editing an alternative to transgenic technology; leveraging water resources and initiating integrated water use policy; strengthening warehousing and cold chain facilities to curb post harvest losses; value addition through food processing; overcoming deficiencies in agricultural marketing through e-NAM; special focus on dryland areas; adopting smart nutrient management practices; regular income through integrated farming systems approach; income enhancement through diversification and professionalization; promoting agri-tourism and rural non-farm employment; structural reforms in agriculture pertaining to land leasing and market restrictions need to be addressed; agriculture to be brought to the concurrent list of the constitution for better central planning; establishing Special Agriculture Zones (SAZ) by selecting export oriented and industrial use crops; promoting scientific agriculture micro-irrigation along with the nutrient application on a very large scale; precision agriculture; harnessing solar energy; agricultural diversification including secondary and specialty agriculture and leveraging the flagship programmes of the government. By adopting the above said approaches in an integrated manner, the objective of doubling farmer's income can be achieved.

CAN IDENTIFICATION OF NITROGEN EFFICIENT CULTIVARS HELP IN ADDRESSING THE PRESSING CHALLENGE OF SUSTAINABLE AGRICULTURE?**PEERSAFFEULLAH¹, TINU ANAND KAIN¹, SHAHID UMAR¹, TARIQ OMAR SIDDIQI¹**¹ Department of Botany, Jamia Hamdard, New Delhi, India-110062

A marked increase in food production has occurred over the past half-century to feed the growing population, which is mainly attributed to application of chemical fertilizers. However, excess inputs of fertilizers also results in severe environmental pollution, climate change and biodiversity loss, which is an enormous environmental challenge of the 21st century. It is estimated that more than 120 million tons of N fertilizers is used annually and less than half of the N applied in developing countries was taken up by crops. Thus reducing fertilizer usage but maintaining crop yield is a pressing challenge. One of the ideal ways to tackle this crisis is to improve NUE of crops. One approach is the identification of new cultivars that utilize N more efficiently. Therefore, our study emphasizes on screening of genotypes on the basis of their Nitrogen efficiencies. An experiment was conducted in the herbal garden of Jamia Hamdard, New Delhi, to study the variations in Nitrogen efficiency (NE) of sixteen accessions of Cauliflower (*Brassica oleracea* L. var *botrytis*) developed by the IARI and IVRI. Cultivars were grown with (60, or 120 kg N ha⁻¹) or without application of N fertilizer. Curd and Shoot yield and N-content were measured and NE was calculated. Nitrate reductase activity was also assayed and plants were screened as low, medium or High N efficient cultivars. The study suggests that the use and identification of high N efficiency accessions might help in addressing the problems of environmental pollution and lead to sustainable agriculture.

Keywords: Sustainable agriculture, Nitrogen efficiency, cauliflower, N fertilizer, screening,

QUALITY SEED PRODUCTION THROUGH SEED CERTIFICATION: A KEY COMPONENT FOR DOUBLING THE FARMERS' INCOME**PEEYUSH KUMAR JAYSAWAL¹, S.K VERMA, PRACHI PANDEY²**¹ Department of Agronomy, ² Department of Genetics and Plant Breeding I. BHU Varanasi-221005, India

A farmer's entire crop depends on the quality of the seed he sows. Therefore it is necessary to produce quality seed for which seed certification is an important step. Seed certification is a legally sanctioned system to maintain quality of seeds during seed production, post harvest operation and distribution of seeds. It is a quality assurance process which includes field inspection, seed quality test, pre and post quality check. It is carried out by Seed certification agency (SSCA) of the concerned state or by National seed corporation (NSC) where such an agency does not exist. The process of seed certification is initiated by an application by the seed grower to the concerned SSCA for certifying the seed produced by him. The application should provide details about the location of farm area of seed plot, crop variety, and the class of seed proposed to be produced, isolation etc. The application is made well in advance of sowing. The SSCA scrutinizes such and on being satisfied, carries out field inspections and seed tests to ascertain the suitability of seed crop for certification. If seed lot satisfies the prescribed purity and quality requirements, SSCA issues suitable tags of certification for affixing them to the seed bag under certification. The validity period of the certificate is nine months from the date of test at the time of initial certification. The validity period could be further extended for six months provided on retesting seed conforms to the prescribed standards in respect of physical purity, germination and insect damage for all seeds except vegetative propagating material for which lots shall be re-examined for seed standards specified for respective crop. The main objective of seed certification is to ensure the acceptable standards of seed viability, vigour, purity and seed health.

Key words: Seed certification, Isolation, Field inspections, validity period

AWARENESS OF DRUDGERY REDUCTION FARM TOOLS AMONG RURAL WOMEN IN AGRICULTURE**PETLA PRIYANKA¹ AND DR. DEEPAK KUMAR MOHANTY²**

1: M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 2: Dept. of Ag. Engineering, Krishi Vigyan Kendra Mayurbhanj-II, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Rural women play a major role in country's economy through their active participation in agricultural activities. They involve in agricultural and allied fields like the crop production, irrigation, manuring, post harvest operations, agro/social forestry, livestock activities, fisheries, etc. The extent of women's involvement and type of activities performed by them in agriculture and allied fields varies greatly from state to state even within a state. These works which lead to "drudgery" is conceived as physical and mental strain, agony, monotony and hardship experienced by human beings while all of the women in the is regard is alarming as they continue to be constrained by illiteracy, malnutrition, and unemployment. So the need of the day is to empower the farm women through technology to have high efficiency in their work output and reduce drudgery through women friendly farm tools and implements. Rural women are not always aware of the improvements they could make by using scientific and technological knowledge. Thus, the attention of rural women was directed towards the women friendly improved farm tool. Rural women from the unorganized sector are vulnerable as new and improved technologies are inaccessible for them. It is imperative that they are exposed to these technologies and encouraged and

motivated to adopt the new technologies which would help them to improve their quality of life.

Keywords: Farm women, drudgery and quality.

HORTICULTURAL INNOVATIONS, FOOD PROCESSING AND VALUE ADDITION

PINGIDI SOUJANYA¹, AMIT KUMAR SHUKLA², THOTHA ANITHA³, BADA MAHESWARA REDDY⁴

^{1,2,3,4} *Faculty of Bhagwant University, Ajmer, Rajasthan, 305 004*

Abstract: The horticulture sector is considered as the most dynamic and sustainable segment of agriculture in all over the world. It covers pre- and postharvest management of a wide spectrum of crops, including fruits and nuts, vegetables (including potatoes), flowering and aromatic plants, tuber crops, mushrooms, spices, plantation crops, edible bamboos etc. Shifting food pattern in wake of increasing income and health awareness of the populace has transformed horticulture into a vibrant commercial venture for the farming community all over the world. In order to optimize the use of resources, hi-tech interventions like precision farming, which comprises temporal and spatial management of resources in horticulture, is essentially required. Infusion of technology for an efficient utilization of resources is intended for deriving higher crop productivity per unit of inputs. This would be possible only through deployment of modern hi-tech applications and precision farming methods. For improvement in crop production and returns to farmers, these technologies have to be widely spread and adopted. Considering the above-mentioned challenges of horticulturist and their expected role in ensuring food and nutritional security to mankind, a compilation of hi-tech cultivation techniques and postharvest management of horticultural crops is needed. When conditions are not suitable for storage or immediate marketing of fresh produce, many horticultural crops can be processed using simple technologies. There are some processing methods that can be used by small-scale handlers, including drying, fermenting, canning, freezing, preserving and juicing. Fruits, vegetables and flowers can all be dried and stored for use or sale in the future. Fermentation is popular throughout the world as a food preservation method, and over 3,500 individual fermented foods have been described by Campbell-Platt (1987). Fruits and vegetables can be canned or frozen, and fruits are often preserved in sugar or juiced. Value-added to horticultural waste streams and over supply using extraction, separation, concentration and stabilization of specialized ingredients such as fiber and bio actives to improve fresh shelf-life by modified atmosphere packaging, post-harvest coating, dips technologies and sanitation practices. Develop products such as fruit snacks and chilled soups and beverages such as fruit juices that retain fresh-like characteristics by using novel technologies (high pressure processing, pulsed electric field, ultraviolet, short-time heat processing).

Key Words: horticulture, innovations, processing, Value-add, food *etc.*

VERMICOMPOSTING AND ITS IMPORTANCE IN IMPROVEMENT OF SOIL NUTRIENTS AND AGRICULTURAL CROPS

PIYUSH CHOUDHARY^{1*}, D.P. SINGH², HEMRAJ JAT², S.K. YADAV¹, GOGRAJOLA¹,

¹ *Department of Agronomy,* ² *Department of Agricultural Chemistry and Soil Science, Rajasthan College of Agriculture (MPUAT), Udaipur, Rajasthan*

The tremendous increase in population, urbanization, industrialization and agricultural production results in accumulation quantities of solid wastes. Vermicomposting involves the utilization of earth worms to manage organic wastes and transform them into a stabilized product without including at hermophilic phase (Riggle and Holmes 1994). The vermicompost quality is the most essential criterion in recycling organic waste. It improves soil aeration and texture thereby reducing soil compaction. It improves water retention capacity of soil because of its high organic matter content. It also promotes better root growth and nutrient absorption and improves nutrient status of soil, both macro-nutrients and micro-nutrients (Punjab State Council for Science and Technology, 2010). Vermicompost involves aerobic decomposition of organic waste by using microorganisms. Maximizing the waste-processing rate depends on maintaining high earthworm density throughout the vermicomposting process. *Eisenia foetida* is the most universally known, other earthworms have also been studied, such as *E. andrei* (Castillo *et al.* 2005), *Eudrilus eugeniae* (Padmavathiamma *et al.* 2008). In an ideal condition earthworms can consume practically all kinds of organic matter and they can eat their own body weight per day for example one kilogram of worms can consume one kilogram of residues every day. And yet their casts contain eight times as many microorganisms as their feed. And the casts don't contain any disease pathogens-pathogenic bacteria are reliably killed in the worm's gut. Worm casts also rich in nutrients such as Nitrogen, Phosphorous and Potassium.

IDENTIFICATION AND ISOLATION OF SEEDBORNE FUNGI ASSOCIATED WITH WHEAT FROM JOBNER VICINITY (JAIPUR)**PIYUSH GOSAIN¹, R. RAHIR, PRAVEEN MANGAL²**¹Department of Plant Pathology, S.K.N. College of Agriculture, SKNAU, Jobner-303329, ²Department of Plant Pathology, S.K.N. College of Agriculture, SKNAU, Jobner-303329

A total of eight seed samples were collected from farmers field situated 10-30 kms away from college campus, Jobner (Jaipur). Seed samples were categorized in six groups i.e., Shrivelled, Discoloured, Mechanically and insect damaged, Impurities (plant debris, stone, sand) and apparently healthy seeds. The range of seed moisture varies (13.30 - 15.20%) & germination (83.30% - 85.80%) & maximum healthy seedling (75.70%) were observed. The total spore load/seed in various samples ranged from (6.33×10^3) to (16.05×10^3) by seed washing test. The samples were tested for fungal seedborne pathogens by using the standard blotter method and agar plate method. Present study revealed seven different seedborne fungi viz., *Alternaria alternata*, *Aspergillus flavus*, *Aspergillus niger*, *Curvularia lunata*, *Fusarium oxysporum*, *Rhizopus stolonifer* and *Penicillium spp.* *Aspergillus flavus* was predominance with an infection range of (4.90-11.00) by blotter method and (5.15-11.00) by agar plate method.

IMPORTANCE OF GENETIC ENGINEERING AND ITS ROLE IN DEVELOPMENT OF SALT TOLERANCE**POOJA KHORANIYA¹, SURESH KUMAWAT², SUNIL KUMAR GORA³**

* Department of Nematology, ** Department of Soil Science and Agricultural Chemistry, *** Department of Soil Science and Agricultural Chemistry, RCA Udaipur, M.P.U.A.T Udaipur, Rajasthan 313004 (India), College of Agriculture, S.K.R.A.U-Bikaner, Rajasthan-334 006 (India)

We believe that the most significant changes in crops will come out by applying genetic engineering tools. Crops may be bioengineered to produce modified kinds of starch, oils and high-value proteins for better nutrition, medical diagnostics and industrial uses. For example, walnuts and peanuts containing healthier oils, along, could become available to consumers. Seedless vegetables and other fruits should appear in the marketplace within 10 years. Oil-producing seed crops may be modified to create specialty oils for a variety of nonfood products such as detergents, lubricants, inks and dyes. Feed seeds engineered to produce higher concentrations of sulfur-containing amino acids could improve wool growth in sheep. Plants could be modified to deliver oral vaccines that prevent diseases such as hepatitis and influenza. Although the tolerance of saline conditions by plants is variable, crop species are generally intolerant of one-third of the concentration of salts found in seawater. Attempts to improve the salt tolerance of crops through conventional breeding programmes have met with very limited success, due to the complexity of the trait: salt tolerance is complex genetically and physiologically. Tolerance often shows the characteristics of a multigenic trait, with quantitative trait loci (QTLs) associated with tolerance identified in barley, citrus, rice, and tomato and with ion transport under saline conditions in barley, citrus and rice. Physiologically salt tolerance is also complex, with halophytes and less tolerant plants showing a wide range of adaptations. We have possible ways, which were appropriate at that time, to develop salt-tolerant crops: (1) develop halophytes as alternative crops; (2) use interspecific hybridization to raise the tolerance of current crops; (3) use the variation already present in existing crops; (4) generate variation within existing crops by using recurrent selection, mutagenesis or tissue culture, and (5) breed for yield rather than tolerance.

Keywords- Genetic Engineering, Salt Tolerance and Crop Resistance to insect pests**RECENT ADVANCES OF SALT TOLERANCE IN TROPICAL AND SUBTROPICAL FRUITS CROPS****POOJA KUMARI, ABHA KUMARI, ARYAMA DEEPTI, SONI KUMARI, NEHA KUMARI**

Department of Horticulture (Fruit and Fruit Technology), Bihar Agricultural University, Sabour, Bhagalpur-813210, India

Salt stress is one of the major abiotic threats to plant life and plant agriculture worldwide and significantly reduces crop yield in affected areas. Excessive salt above the tolerable limit hamper the plant growth and productivity and extreme condition may lead to plant death. About 20% of all irrigated land is affected by soil salinity, decreasing crop yield. Plants are affected by salt stress in two ways: osmotic stress and ionic toxicity. These stresses affect all the major plant physiological processes including photosynthesis, cellular metabolisms, and plant nutrition. Plants can be divided into two categories in regards to salt stress: glycophytes and halophytes. Glycophytes are extremely sensitive to salt in soils; halophytes are salt tolerant and often grow in salty environments. There are some newly developed salt tolerant rootstocks namely Attani-1 and Attanti-2 in Citrus, Khistwai and Barban in Date palm. Under stress condition proline acts as osmoprotectant and a storage source of nitrogen and may be engineered into citrus for higher salt tolerance. Paclobutrazol (PBZ) play an important role in promoting the avoidance of salt stress in mango by increasing the levels of photosynthetic pigments, water content, K⁺ uptake and its accumulation, reducing defoliation, membrane injury index and uptake and accumulation of harmful Na⁺ and Cl⁻ ions and minimises the effects of salt stress. *In vitro* studies related to abiotic stress provide more understanding of the effect of salinity and draught on date palm cell callus cultures tolerance. Pandey *et al.*, in 2014 suggested that lower levels of Cl⁻ and Na⁺ accumulation could be used as indicators for screening mango rootstocks for resistance to NaCl stress and based on overall performance, salinity tolerance

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

increased in the following order Chandrakaran < Moovandan < Bappakai < Nekkare < Kurukkan < Terpentine < Olour. The use of plant growth-promoting bacterial (PGPB) endophytes that contain 1-aminocyclopropane-1-carboxylate (ACC) deaminase has the potential to facilitate plant growth on land that is not normally suitable for the majority of fruit crops due to their high salt contents.

REMOVAL OF HEAVY METAL FROM WATER AND SOIL

POOJA NAIN¹, YOGITA NAIN² AND RATAN LAL SHARMA³

¹Department of soil science and agriculture chemistry, SKNAU, Jobner (Jaipur) ²Department of plant pathology JNKVV, Jabalpur (MP)

³Department of Plant Pathology, SKNAU, Jobner (Jaipur)

At many sites around the nation, heavy metals have been mined, smelted, or used in other industrial processes. The waste (tailings, smelter slag, etc.) has sometimes been left behind to pollute surface and ground water. The heavy metals most frequently encountered in this waste include arsenic, cadmium, chromium, copper, lead, nickel, and zinc, all of which pose risks for human health and the environment. They typically are spread out over former industrial sites and may cover acres of land. Mine spoils (locally called chat) cover much of the open space inside the city, and contain high levels of lead, zinc, and cadmium. Heavy metal contamination can be carried with soil particles swept away from the initial areas of pollution by wind and rain. Once these soil particles have settled, the heavy metals may spread into the surroundings, polluting new areas. Cleanup (or remediation) technologies available for reducing the harmful effects at heavy metal-contaminated sites include **Excavation** (physical removal of the contaminated material). Advantages of excavation include the complete removal of the contaminants and the relatively rapid cleanup of a contaminated site. **Stabilization** of the metals in the soil on site, and the use of growing plants to stop the spread of contamination or to extract the metals from the soil (**phytoremediation**). Growing plants can help contain or reduce heavy metal pollution.

MOLECULAR ANALYSIS OF YR GENES IN WHEAT (*TRITICUM AESTIVUM* L. EM. THELL)

POOJA^{1*}, S.S. DHANDA¹, PRINCE², N.R. YADAV³ AND R.S. BENIWAL⁴

^{1*}Department of Genetics and Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar-125004 Haryana, India., ¹Department of Genetics and Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar-125004 Haryana, India., ²Department of Horticulture, Chaudhary Charan Singh Haryana Agricultural University, Hisar-125004 Haryana, India., ³Department of Molecular biology, Biotechnology and Bioinformatics, Chaudhary Charan Singh Haryana Agricultural University, Hisar- 125004 Haryana, India

The present investigation entitled was conducted to evaluate 210 recombinant inbred lines of bread wheat to estimate variability, promising RILs, the associations among the various traits and to identify *Yr* genes using SSR markers. High and medium values of GCV, PCV, heritability and genetic advance as percent of mean for grain yield per plant and biological yield in both years indicating a high scope of selection for these traits followed by 100-grain weight, number of spikelets per ear, harvest index, days to heading and days to maturity. Grain yield was significantly and positively correlated with biological yield, harvest index, number of tillers per plant, ear length, number of spikelets per ear, plant height and number of grains per ear, whereas negative and significantly correlated with days to heading in both years. Biological yield and harvest index had high direct and indirect effects on grain yield per plant over the years, indicating the true relationships with grain yield, in this set of material. The RIL No. 52 had better performance for the traits loaded on PC-2, namely grain yield per plant, biological yield and number of tillers per plant and showed 4 *Yr* genes (***Yr7*, *Yr36*, *Yr47*, *Yr53***). This line also showed better performance than mean values in terms of grain yield and its components. The lines viz, RIL No. 13, 24, 31, 120, 121, 134 showed a desirable combination of the traits loaded on PC-1 and PC-2, namely grain yield per plant, biological yield and number of tillers per plant and complemented with disease resistance. The RIL No. 117, 25, 12, 15 had better performance for the traits loaded on PC-1, namely grain yield, biological yield and ear length and showed 2 *Yr* genes (***Yr7*, *Yr47*, *Yr18*, *Yr36*, *Yr26*, *Yr29*, *Yr26*, *Yr29***) respectively. The RIL Nos. 12, 15, 25 were also showed better performance than mean values in terms of grain yield and its components. Fifteen, out of 70 SSR markers were found polymorphic in parental genotypes and in RILs. The gene *Yr7*, *Yr18*, *Yr26*, *Yr29*, *Yr36*, *Yr47* and *Yr53* were linked to yellow rust resistance in the present investigation.

Keywords: Bread wheat, diversity, yellow rust, SSR markers, *Yr* genes

INTEGRATED PLANT DISEASE MANAGEMENT OF BACTERIAL DISEASE

POOJASHREE, R.

Department of plant pathology, College of Agriculture, G.B. Pant University of Agriculture & Technology, Pantnagar, Uttarakhand

Major economic losses in agriculture production due to diseases are need to be reduced in order to meet increasing global food demands associated with growth in human population. Particularly on disease control for many bacterial incited disease facing challenges because

of pathogen diversity, high rate of multiplication of bacteria in relatively short period of time, inability to identify durable resistance in host plant to the target pathogen and lack of effective chemical control measures. For most of plant diseases, including bacterial incited diseases, an integrated management strategy is essential. Since current control measures involving the use of traditional chemicals or antibiotics are losing their efficacy due to natural development of bacterial resistance. There is a well recognized need to develop new ecofriendly control measures to combat bacterial crop diseases. Bacteriophages, the viruses of bacteria, have received increased research interest in recent years as a realistic environment friendly means of controlling bacterial diseases. Unlike chemical biocides, phages occur naturally in the environment and humans are thus exposed to them on daily basis without any harm. After application their number increases if their target bacterial host species are accessible to them. Their use presents a viable control measures for a number of destructive bacterial crop diseases, with some phage based products already becoming available on the market. Phages can be used effectively as part of integrated disease management strategies especially with other biocontrol agents. The relative ease of preparing phage treatments and low cost of production of these agents make them good candidates for widespread use in developing countries as well.

THE IMPACT OF A BIO-FERTILIZER ON THE SOIL ORGANIC MATTER STATUS AND CARBON SEQUESTRATION RESULTS FROM A FIELD-SCALE STUDY

POONAM KUMARI YADAV AND SANTOSH YADAV

Long-term soil and crop management such as the excessive use of inorganic fertilizers and pesticides along with the use of heavy machinery, and in-adequate practices of soil management exert a considerable influence on soil quality by worsening the physicochemical and biological properties of the soil. The application of bio-fertilizers is one of the management practices that can help to maintain or increase the content of organic matter (OM) and improve soil fertility in arable soils. The application of UGmax on arable soil resulted in significant changes in the quantity and quality of soil organic matter. Organic matter in the soil treated with UGmax had a higher TOC content, a higher content and contribution of CHAs and C humin in TOC, higher CHAs/CFAs ratio and a lower content of DOC as compared to the control. The use of a bio-fertilizer that increases the formation of permanent humus compounds provides evidence of an increase in the soil organic matter stability. Consequently, the contribution of the organic matter fractions that are more resistant to decomposition is crucial for increasing soil carbon sequestration. Therefore, beneficial soil microbes should be further studied and exploited for the development of sustainable agriculture as an ecological alternative for soil fertility management.

COMPOSITION OF VERICOMPOST AND USE IN AGRICULTURE

POONAM KUMARI, OM PRAKASH YADAV, ANIL KUMAR, VIRENDRA SINGH SHEKHAWAT

Department of Plant Pathology, RCA, Udaipur (MPUAT) Rajasthan, India

Vermicomposting is the process of producing organic fertilizer or the vermicompost from bio-degradable materials with earthworms. Vermicomposts have higher level of available nutrients like carbon nitrogen, phosphorous and potassium, calcium and magnesium derived from the wastes. In vermicomposting three varieties of earthworms used such as *Eisenia fetida*, *Eudrilus eugeniae* and *Perionyx excavates* in the vermicomposting of plant debris, cattle dung and waste paper mixture of waste paper, plant debris and cattle dung in the ratio of 1:1:1 was found to be the best ratio than 3(paper waste): 2(cattle dung) and 5(plant debris). In 60 days time excellent quality and quantity of compost was produced by three earthworms. The ranges of EC, pH, C/N and germination index were 7.5-4.9 mS/cm, 5.6-7.53, 30.13-14.32% and 12.8-58.4%, respectively. The C/N value showed that the vermicompost was stable. Vermicompost is accepted as humus biofertilizer, soil fertility booster, soil activator and soil conditioner with required plant nutrients of storage polysaccharides and structural polysaccharides, vitamins, enzymes, growth regulators and beneficial microorganisms like nitrogen fixing, phosphate solubilising, denitrifying, decomposing bacteria and methanogenic bacteria. "The Green Revolution" that was promoted in early part of 20th century, was a boost to food production without foreseeing its ill effects. The present trend about waste management is to focus on recycling and the recovery of waste as new materials or as energy. Advantages of vermicompost include enriching soil, increasing harvest yields and suppressing plant disease. Vermicomposting enriching soil, increasing plant growth and yields and suppressing disease. Damping off, seedborne such as *Pythium*, *Phytophthora*, *Rhizoctonia* species successfully suppress these disease.

Key words: Vermicompost; Plant debris; Paper waste; Cattle dung; *Eisenia fetida*; *Eudrilus eugeniae* and *Perionyx excavates*

VERTICAL FARMING: FUTURE FARMING

POONAM SAINI* AND HEMANT SAINI

M.Sc student, Department of Horticulture, College of Agriculture, CCSHAU, Hisar- 125 004 (Haryana)

Traditional farming is taking a huge toll on the environmental problem that's set to worsen due to our ever-growing global population. Yet there are some high-tech solutions. Here's what you need to know about the burgeoning practice of controlled-environment agriculture and how it's set to change everything from the foods we eat to the communities we live in. As a solution, an increasing number of

horticulturalists and entrepreneurs are turning to controlled-environment agriculture (CEA), and the related practice of vertical farming. While not a total panacea, these high-tech farms are doing much to address many of the problems associated with conventional farming practices. Vertical farming is the practice of producing food and medicine in vertically stacked layers, vertically inclined surfaces and/or integrated in other structures (such as in a skyscraper, used warehouse, or shipping container). The modern ideas of vertical farming use indoor farming techniques and **controlled-environment agriculture** (CEA) technology, where all environmental factors can be controlled. These facilities utilize artificial control of light, environmental control (humidity, temperature, gases) and **fertiligation**. Some vertical farms use techniques similar to **greenhouses**, where natural **sunlight** can be augmented with artificial **lighting** and **metal reflectors**. Vertical farms can help meet our growing population's needs by offering an additional way to produce food that does not share the same volatility and risk as conventional agriculture. While vertical farms require less water and arable land than conventional farms, they are not carbon neutral. Their climate footprint depends heavily on the source from which they draw their electricity to power lighting and control the indoor environment. As renewable energy sources become adopted more widely, the carbon cost of vertical farming will continue decreasing. From a market perspective, it may not bring down prices, but on a societal level, the hope is that vertical farming can help address gaps in overall food demand where conventional agriculture fails.

Keywords: Vertical Farming, Conventional Farming, CEA (**controlled-environment agriculture**), Fertiligation

HYDROPONIC GREENHOUSE: INCREASING FARMER INCOME

POORNIMA DEVI¹ AND DR. J.P.SINGH¹

1. Department of Horticulture, C.S.A. U.A & T, Kanpur (U.P)

Hydroponics is a modern technology supporting the application of integrated crop management in greenhouse. It is a modern technology involving plant growth on inert media in place of the natural soil, in order to uncouple the performance of the crop from problems associated with the ground, such as soil-borne diseases, non-arable soil, poor physical properties, etc. In combination with greenhouses, hydroponics is becoming increasingly popular. It is high technology and capital intensive. It is highly productive, conservative of water and land and protective of the environment. A balanced distribution of small and larger pores is required in a substrate to ensure adequate availability of water to the plants without to affect the supply of oxygen to the roots. Various non-toxic porous materials are used as plant growth substrates, including rockwool, perlite, pumice, expanded clay, various volcanic materials, polyurethane foam, coir dust, etc. Hydroponics has no adverse effect on the quality of fruits, vegetables and flowers produced in such systems. For production of leafy vegetables and herbs, deep flow hydroponics is common. Organic fertilizers can also be used to supplement or entirely replace the inorganic compounds used in conventional hydroponic solutions. Computers today operate hundreds of devices within a greenhouse by utilizing dozens of input parameters to maintain the most desired growing environment. The technology of greenhouse food production is changing rapidly with systems today producing yields never before realized. The future development of hydroponic/soilless cultured systems appears more positive today than any time over the last 50 years.

Keywords: Hydroponics, soil, crop, greenhouse, environment.

IMPACT OF VARIABLE PRUNING INTENSITIES OF *DALBERGIA SISSOO* ON GROWTH AND YIELD ATTRIBUTES OF MUSTARD VARIETIES UNDER AGROFORESTRY SYSTEM IN CENTRAL INDIA

POORNIMA MALVIYA*, RAHUL DONGRE, S. D. UPADHYAYA AND B.D. GHODE

Department of Forestry, College of Agriculture, JNKVV, Jabalpur

The present investigation was taken up with 19 years old agrisilviculture system (*Dalbergia sissoo*+ mustard) during *rabi* season of 2017-18 under AICRP on Agroforestry, Department of Forestry, JNKVV, Jabalpur, M.P. The planting geometry of *Dalbergia sissoo* was 5 × 5 m. The treatment combinations involved four pruning treatments (viz., no pruning, 25% pruning, 50% pruning and 75% pruning) and one open (without tree) in main plot and three mustard varieties (viz., JM-3, Urvashi and NRCR-2) in sub plot. The experiment was laid out in strip plot design with four replications. The soil of the experimental area was medium black. Clay sandy loam with pH 6.0 (acidic), high in organic matter (0.81), medium in available nitrogen (288.1 kg ha⁻¹), high in available phosphorus (20.38 kg ha⁻¹) and low in available potash (170 kg ha⁻¹). In intercropping with *Dalbergia sissoo* three mustard varieties were sown in 45 cm row spacing. The result revealed that crop under open condition recorded significantly higher plant height (142.92 cm), number of branches/plant (6.68), number of siliqua/plant (133.64), length of siliqua (6.08 cm), number of seeds/siliqua (12.05) and 1000 grain weight (4.68 gm). Open condition (without tree) recorded significantly higher grain yield (670 kg ha⁻¹) which was significantly superior to other pruning treatments. Among different pruning treatments 75% pruning recorded significantly higher grain yield (461 kg ha⁻¹) at par with 50% and 25% pruning but significantly superior to no pruning which recorded the lowest grain yield (352 kg ha⁻¹). The percent reduction in grain yield under no pruning, 25%, 50% and 75% pruning as compared to open condition was 47.4%, 36.8%, 34.7% and 31.1%, respectively. Mustard variety i.e. urvashi recorded higher grain yield (509 kg ha⁻¹) at par with NRCR-2 variety (487 kg ha⁻¹) and superior to variety JM-3 which recorded significantly lowest grain yield of 410 kg ha⁻¹. The percent increase in yield under urvashi over NRCR-2 and JM-3

was 4.3 and 19.4 % respectively. Managed agroforestry system gave higher monetary return (Rs. 61628 ha⁻¹) as compared to unmanaged agroforestry system i.e. no pruning (Rs.66349 ha⁻¹). Under managed agroforestry system mustard+ *D.sissoo* in 25% pruning recorded higher monetary return (Rs.80225 ha⁻¹) as compared to crop alone (Rs.19793 ha⁻¹) and tree alone (Rs.48847 ha⁻¹).

Key Words: Agroforestry system, Mustard, *D. sissoo*, Monetary Return

ROLE OF PLANT GROWTH PROMOTING RHIZOBACTERIA IN AGRICULTURE

POPIN KUMAR¹, SACHIN KUMAR², KRISHNA KUMAR¹ AND AKSHAY KUMAR²

Department of Plant Pathology¹/ Department of Entomology², Narendra Deva University of Agriculture and Technology Narendra Nagar, Kumarganj, Faizabad, (U. P.) 224229, India

Plant growth promoting rhizobacteria (PGPR) shows an important role in the sustainable agriculture industry. The increasing demand for crop production with a significant reduction of synthetic chemical fertilizers and pesticides use is a big challenge nowadays. The use of PGPR has been proven to be an environmentally sound way of increasing crop yields by facilitating plant growth through either a direct or indirect mechanism. The mechanisms of PGPR include regulating hormonal and nutritional balance, inducing resistance against plant pathogens, and solubilizing nutrients for easy uptake by plants. In addition, PGPR show synergistic and antagonistic interactions with microorganisms within the rhizosphere and beyond in bulk soil, which indirectly boosts plant growth rate. Agriculture is one of the human activities that contribute most to the increasing amount of chemical pollutants via excessive use of synthetic chemical fertilizers and pesticides, which cause further environmental damage with potential risks to human health. Nitrous oxide (N₂O) is an example of chemical pollutant produced by excessive use of nitrogen fertilizer and is a major source of greenhouse gases causing global warming. PGPR plays an important role in enhancing plant growth through a wide variety of mechanisms. The mode of action of PGPR that promotes plant growth includes (i) abiotic stress tolerance in plants; (ii) nutrient fixation for easy uptake by plant; (iii) plant growth regulators; (iv) the production of siderophores; (v) the production of volatile organic compounds; and (vi) the production of protection enzyme such as chitinase and glucanase. Nitrogen fixation is one of the most beneficial processes performed by rhizobacteria. Nitrogen is a vital nutrient to plants and gaseous nitrogen (N₂) is not available to them due to the high energy required to break the triple bonds between the two atoms. Rhizobacteria, through nitrogen fixation, are able to convert gaseous nitrogen (N₂) to ammonia (NH₃) making it an available nutrient to the host plant which can support and enhance plant growth. The host plant provides the bacteria with amino acids so they do not need to assimilate ammonia. The amino acids are then shuttled back to the plant with newly fixed nitrogen. Nitrogenase is an enzyme involved in nitrogen fixation and requires anaerobic conditions. Membranes within root nodules are able to provide these conditions. The rhizobacteria require oxygen to metabolize, so oxygen is provided by a hemoglobin protein called leghemoglobin which is produced within the nodules. Legumes are well-known nitrogen-fixing crops and have been used for centuries in crop rotation to maintain the health of the soil. Rhizobacteria are also able to control plant diseases that are caused by other bacteria and fungi. Disease is suppressed through induced systematic resistance and through the production of antifungal metabolites. *Pseudomonas* bio control strains have been genetically modified to improve plant growth and improve the disease resistance of agricultural crops. In agriculture inoculants bacteria are often applied to the seed coat of seeds prior to being sown. Inoculated seeds are more likely to establish large enough rhizobacterial populations within the rhizosphere to produce notable beneficial effects on the crop.

STUDIES ON EFFICACY OF BIO-AGENT AND MANAGEMENT OF ALTERNARIA LEAF SPOT OF BROAD BEAN IS CAUSED BY *ALTERNARIA ALTERNATA* (FRIES).

POPIN KUMAR¹, KRISHNA KUMAR¹, AKSHAY KUMAR² AND MANJEET KUMAR³

Department of Plant Pathology¹/ Department of Entomology², Department of Vegetable Science, Narendra Deva University of Agriculture and Technology Narendra Nagar, Kumarganj, Faizabad, (U. P.) 224229, India

Faba bean (*Vicia faba* L.) is belonging to family Fabaceae, which is native to North and Southwest of Africa and popularly known as bakala in India, broad bean, field bean tick bean, hors bean, (small type) etc. It is one of the earliest domesticated food legumes in the world and provides protein requirement of human diet and also a chief source of calcium, iron and vitamins and ranks high among the vegetable. Sprouted seed is a rich source of vitamin A and C. Nutritive value of faba bean is high with about 30 % protein, carbohydrate 56%, fat 0.8 %, crude fiber 6.61-8.54%, ash 3.45% and lipid 1.63% (Crepon *et al.* 2010). Faba bean ranks fourth in the world as an important food legume after garden pea, chickpea and lentil (Torres *et al.* 2006). The leading faba bean producing countries are China, Ethiopia and Egypt (Tekalign, 2014; FAOSTAT, 2017). Faba bean plants infected with many fungal pathogens which caused a considerable yield losses (Mahmoud and Nagwa, 1996). Also it attacked by many foliar diseases such as; chocolate spot (*Botrytis fabae* and *B. cinerea*), Alternaria leaf spot (*Alternaria alternata*), rust (*Uromyces fabae*), downy mildew (*Peronospora viciae*). As well as, root-rots and viral diseases, which are responsible to cause considerable losses in the yield and its component. In general; chocolate spot disease was the major problem of faba bean plants. However, Alternaria leaf spot disease comes predominant on faba bean in many countries (Reis *et al.*, 2007 and Juroszek 2011). Leaf spot of *Vicia faba* (Faba bean) caused by *Alternaria alternata* (Fries) Keissler is one

of the most serious diseases in many areas of Bihar and Jharkhand. Under severe conditions of infection yield loss up to 40 per cent has been reported (Upadhyay and Kumar, 2005). **The evaluated the efficacy** five *Trichoderma harzianum* isolates (T_1 , T_2 , T_3 , T_4 , and T_5). In dual culture plate test revealed that the percentage growth inhibition of *A. alternata* by *T. harzianum* was in the range of 53.85 to 82.81 %. The evaluated nine fungicides against *A. alternata* under *in vitro* condition. Among the tested fungicides Prochloraz (95.3%) found most effective in inhibiting mycelial growth followed by Propineb (65.8%), Saaf (60.5%) and Mancozeb (57.8%). The evaluated the efficacy of different systemic and contact fungicides against early blight of tomato. Among systemic fungicides, Difenconazole inhibited maximum growth of *A. solani* and in contact fungicides, Mancozeb gave highest per cent inhibition.

COMPARATIVE FIELD EVALUATION OF PNEUMATIC PLANTERS FOR VEGETABLE CROPS

PRABHAKAR SHUKLA, MAHESH JADHAV AND ANURAG PATEL

ICAR-Central Institute of Agricultural Engineering, Bhopal

India is the second largest producer of vegetables in the world and accounted for about 15% of the world's production of vegetables with the production level of over 178 million tonnes (mt) from around 10 million hectares (mha) in 2016. The crops of *Brassicaceae* family viz. cauliflower, cabbage and knol-khol etc. were grown on 0.388 mha in 2016 over the country. The total production of the same was 0.88 mt with yield of 22.6 tonnes ha^{-1} in 2016. The conventional method of planting of vegetable crops is manual transplanting. Among different sowing methods, precision sowing is preferred method at present however lack of suitable machines limits the mechanical planting of vegetable crops. Pneumatic planter has the potential of metering irregular shaped seeds, which places the single seed in furrows as per the desired plant to plant spacing by using a rotating seed plate under vacuum pressure. Hence the objective of study was to test and evaluate the field performance of the tractor operated three-row pneumatic planters developed by Centre of Excellence for Farm Machinery (CoEFM), Ludhiana, Punjab and Agricola Italiana SNC (model: SN-1130) for cauliflower, cabbage and knol-khol crops. It was observed that testing field had sandy loam soil with 6.2 % (db) soil moisture content. Lower moisture content helped to avoid furrow opener blocking of pneumatic planter. The suction pressure of the pneumatic chamber was kept as 300, 400 and 500 mmH₂O for the cauliflower, cabbage and knol-khol crops in order. The planters were operated at an average speed of 2.8 km h^{-1} . The row to row distance was maintained as 42 and 44 cm in CoEFM make and Agricola Italiana SNC pneumatic planters with actual field capacities of 0.24 and 0.29 $ha\ h^{-1}$ respectively and their corresponding field efficiencies were 71.92 and 82.25 %.

Key words: field testing, pneumatic planter, cauliflower, cabbage, knol-khol.

"ADVANCES IN MUNG BEAN BY DEVELOPING GENOMIC RESOURCES & FUTURE BREEDING PROGRAMMES"

PRABHAT SINGH, HARSHIT TRIPATHI

Department of Genetics & Plant Breeding, C.S. Azad University of Agriculture & Technology, Kanpur

Mungbean [*Vigna radiata* (L.) Wilczek] is an important legume crop of Asian continent. It is known for easily digestible protein rich seed, sprouts and dal. It also provides a good source of Folate and Iron. Small genome size (579mb) short life cycle, self-pollination are the desirable features makes it model plant. In recent decades many efforts have been taken to develop molecular markers and mapping populations for QTL analysis of polygenic traits for betterment of yield & other attributes. The sequencing of its wild relative *Vigna radiata* var. *sublobata* has provided framework for genetic research in it. The genetic resources of mungbean are maintained at different centres at Global Level as Asian Vegetable Research & Development Centres, Taiwan; Research & Development Authority, Korea; Plant Genetic Resource Conservation Unit, University of Georgia. Earlier the markers used in mungbean before sequencing of genome was RFLP and RAPD but now a days transcriptome marker as well as sequence based genetic marker as Simple Sequence Repeat & Single Nucleotide Polymorphism are developed, These are codominant, single locus, diallelic markers and easily detectable also. Now the era is changed from traditional marker assisted breeding to next generation sequencing for mungbean and its relatives. The objective of regulatory mechanism manipulation is to develop crop that can withstand changing weather pattern, stress and environmental responses and its stability at multilocation.

USE OF MOLECULAR TECHNIQUES FOR IMPROVING GRAIN QUALITY IN RICE

PRACHI PANDEY AND P. K. SINGH

Department of Genetics and Plant Breeding, Institute of Agricultural Sciences, Banaras Hindu University

Rice which is the world's most important food crop, is a rich source of carbohydrate. It is a staple food and most economic crop of most part of the world. The increasing population of world demands high yielding and nutritional quality of grains. Quality expected in rice grains varies according to geographical region and on consumer demand. Molecular marker techniques are currently the most advanced method available for the transfer of desired gene in desired rice variety with required combination. The known genes or quantitative trait loci can successfully be applied in breeding programs for marker assisted selection (MAS) to improve the breeding and selection efficiencies. Many QTLs and genes have already been mapped or characterized, which help to understand the genetics of grain quality of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

rice. Different validated markers will facilitate marker assisted breeding for grain quality. Various genes can also be pyramided together using gene pyramiding method to obtain desired grain quality according to consumer preferences across the world. Therefore, modern breeding techniques MAS and QTL mapping play an important role in ensuring high yield with excellent quality traits in rice grains and their application is a novel prospect for enhancement of rice yields.

EFFECT OF IRON IN GROWTH, YIELD AND NODULATION OF GREEN GRAM (*VIGNA RADIATE L.*) PRADEEP KUMAR AND RABISH DATT SHUKLA

School of Agricultural Sciences and Engineering, IFTM University, Moradabad-244102

The present study entitled Impact of Effect of Iron in growth, yield and Nodulation of Green gram. these carried out at School of Agricultural Sciences and Engineering, IFTM University, Moradabad in 2017-2018. Iron (Fe) is one of the essential micronutrients for higher plant growth and reproduction. Iron plays an important role in nitrate and sulfate reduction and energy production within the plant. These treatments T₁ Control, T₂ RDF + 30kg P₂O₅ + Seed treatment (Fe⁺⁺), T₃ RDF + 30kg P₂O₅ + Seed treatment + One Spray (15 DAS), T₄ RDF + 30kg P₂O₅ + Seed treatment + Two Spray (15 & 30 DAS), T₅ RDF + 45kg P₂O₅ + Seed treatment, T₆ RDF + 45kg P₂O₅ + Seed treatment + One Spray (15 DAS), T₇ RDF + 45kg P₂O₅ + Seed treatment + Two Spray (15 & 30 DAS), T₈ RDF + 60kg P₂O₅ + Seed treatment, T₉ RDF + 60kg P₂O₅ + Seed + One Spray (15 DAS), T₁₀ RDF + 60kg P₂O₅ + Seed + Two Spray (15 & 30 DAS) and three replication.

EMPLOYMENT GENERATION WITH SUSTAINABLE DEVELOPMENT THROUGH SERICULTURE PRADEEP SINGH

Department of vegetable science, CCS Haryana Agricultural University, Hisar-125004

Sericulture, also known as silk farming is an eco-friendly agriculture based labour intensive cottage industries involving mulberry cultivation, silkworm rearing and egg production, reeling and weaving of the loom and other post cocoon processes like twisting, dyeing, painting, finishing etc. along with the utilization of by products, offering a most promising alternative agricultural activity. There are mainly five varieties of silk produced in India such as Mulberry, Tropical Tasar, Oak Tasar, Eri and Munga. Silk is known as the Queen of Textiles the world over. There was 30265 MT silk production in India in the year 2016-2017. Sericulture conserves the environment by non cutting and felling of trees. Sericulture industry provided employment to approximately 8.25 million persons in rural and semi-urban areas in India during 2015-2016. India traditional and culture bound domestic market and an amazing diversity of silk garments that reflect geographic specificity has helped the country to achieve leading position in silk industry.

Key words: Employment, sustainable, sericulture etc.

INTEGRATED RICE-FISH FARMING: A SUSTAINABLE AGRICULTURAL APPROACH PRADOSH KUMAR PARIDA¹, DEBASHIS NAYAK² AND BISWARANJAN SAMANTRAY³

1: M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 2: Dept. of Agronomy, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha, 3: Dept. of Fisheries, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

The integrated rice-fish system is an ancient practice employed by numerous farmers in Asia. China, in particular, has mastered this farming technique where rice and fish grow simultaneously in a symbiotic relationship. It involves a dynamic system of fish poly-culture (a systematic way of rearing fish), production of poultry, livestock and crops, and the "integrated" use of manure, grass and other crops as feeds and fertilizers. Integrated fish farming refers to the coordinated growing of crops as well as rearing of fish in the same plot. This could also involve the rearing of fish. Fish eat weeds and pests, promoting weed control and reducing insect damage. This improves the cultivation of rice, while also reducing fish feed requirements and the use of pesticides. Fish manure serves as fertilizer, and the movement of fish helps turn over and loosen the soil, promoting fertilizer decomposition and root development. With the increasing demand of Rice, both as a major cash and staple crop in India, there is indeed the need for an efficient way of Rice production in reasonably large quantities to meet up with increasing food demand. Fish on the other hand is very essential due to its high nutritional, medicinal and industrial value. This also calls for an improved way of growing fish to meet such high demand.

Keywords: Rice, Fish and integrated.

BIOTECHNOLOGICAL INTERVENTIONS FOR IMPROVEMENT OF FLORICULTURAL CROPS PRAGNYA PARAMITA MISHRA^{1*} AND DURGA PRASAD MOHARANA²

¹Department of Floriculture and Landscaping, O.U.A.T., Bhubaneswar-751 003, ²Department of Horticulture, I.A.G.Sc., Banaras Hindu University, Varanasi-221 005

Floriculture, undoubtedly, has revolutionized the horticultural industry. Floriculture industry requires new plant varieties with elite traits

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

such as improved anatomical attributes, wide range of flower colour, long postharvest life, biotic and abiotic stress resistance, floral architecture, fragrance, productivity, timing, synchronicity of flowering, and other desirable attributes. Apart from being a tool for beautification and style, flowers also give a sense of aesthetic gratification. Since the past century, different biotechnological techniques like tissue culture, micropropagation, specific-pathogen-free plantlet production, hybrid embryo rescue, haploidy/doubled haploids, somatic embryogenesis, transgenic, or GM (genetically modified) based technologies, etc. are contributing significantly to the floricultural sector. Biotechnology plays an important role in developing novel and interesting flowering plants with unique and desirable attributes.

Keywords: Floriculture, biotechnology, transgenic, aesthetic gratification

SURVEY AND CHEMICAL MANAGEMENT OF RICE FALSE SMUT DISEASE

PRAHLAD MASURKAR^{1*}, SUMIT KUMAR PANDEY¹, R K SINGH¹ AND SUMAN KUMAR¹

¹Department of Mycology and Plant Pathology, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi, India (221005)

Rice (*Oryza sativa*) is the most staple food crop in world. False smut of rice (*Ustilagoidea virens*) is one of the major emerging and destructive disease especially in high yielding rice varieties. Survey has been made for disease incidence of rice in infected rice varieties. The incidence of flowering of infected tillers was found ranging from 5 % to more than 50 % in different varieties like Sarjoo 52, NDR 359, HUR- 12. The experimental result revealed that the fungicides Amistar Top (azoxystrobin 18.2 % + difenoconazole 11.4 % w/w SC) Folicur was found most effective where percentage of infective spikelet's per m² reduced to 10.75%. In the term of percentage of infected spikelets/panicle, the treatment with Amistar Top (azoxystrobin 18.2 % + difenoconazole 11.4 % w/w SC) recorded the lowest percentage i.e. 6.35 % which was at par with the treatment Folicur (tebuconazole 250 EC). The grain yield obtained from each plot it was found that the treatment with Amistar Top (azoxystrobin 18.2 % + difenoconazole 11.4 % w/w SC) gave the highest grain yield/plot (49.64 q/ha) which was at par with the Folicur (tebuconazole 250 EC) i.e. 48.92 q/ha.

Key words: Survey, Incidence, Tillers, fungicides etc.

ESTIMATION OF HETEROSIS AND COMBINING ABILITY IN BREAD WHEAT (*TRITICUM AESTIVUM* L.)

PRAKRITI TOMAR*, SANJAY KUMAR SINGH, SOMVEER SINGH, LOKESH KUMAR GANGWAR AND ATAR SINGH

Department of Genetics and plant breeding, Chandra Shekhar Azad University of Agriculture & Technology, Kanpur-208002 India.,
Department of Genetics and plant breeding, Sardar Vallabhbhai University of Agriculture and Technology, Meerut-250110 India.

Heterosis and combining ability analysis were studied in a 6 × 6 diallel set of bread wheat during Rabi 2015-2016 at Crop Research Farm, Nawabganj of Chandra Shekhar Azad University of Agriculture & Technology, Kanpur, (Uttar Pradesh). Observations were recorded on 9 quantitative traits. Analysis of variance for general combining ability (gca) among the parents revealed that all the traits were found highly significant but specific combining ability (sca) for the crosses were observed highly significant for all the traits except number of productive tillers per plant, spike length and grain yield per plant. Combining ability analysis revealed the involvement of both additive and non-additive gene action in the inheritance of most of the traits. Among the parents, K9107, PBW343 and K1006 proved to be good general combiners based on their gca effects as well as per se performance for grain yield. In regards to sca effects, the F₁ hybrids K1006×K9107 and K9107×K607 were exhibited good specific combinations for grain yield. Heterosis at better parent reflected the idea of gene action i.e. dominance, over dominance or recessive. The positive and significant values always indicated over dominance effect of the parents. For grain yield per plant, three cross combinations K1006×K424, K9107×K424, and K607×K424 identified with positive significant over better parent heterosis.

Keywords: Wheat, diallel, GCA, SCA, heterosis.

STUDY ON EFFECT OF TECHNIQUES OF CROP ESTABLISHMENT AND NITROGEN LEVELS ON THE PERFORMANCE OF RICE (*ORYZA SATIVA* L.)

PRAMOD KUMAR*, YOGESH, PRASHANT DEO SINGH**, ANAND SINGH** AND ANKIT SINGH******

*Department of Agronomy, C.S.A.U.A & T, Kanpur; **Department of Agronomy, N.D.U.A & T, Faizabad, ***Department of Soil Science, S.V.B.P.U.A & T, Meerut, ****Department of Agronomy, Rama University

Present investigation entitled "Study on effect of methods of establishment and nitrogen levels on the performance of rice (*Oryza sativa* L.)" was conducted during Kharif 2016 at experimental site of (Agronomy Research Farm), Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.). The experiment was carried out in field with three methods of establishment (M₁- transplanting, M₂-SRI and M₃- direct seeding) were kept in main plots and five nitrogen levels (N₀- 0 kg N ha⁻¹, N₁- 40 kg N ha⁻¹, N₂- 80 kg N ha⁻¹, N₃-120 kg N ha⁻¹ and N₄- 160 kg N ha⁻¹) in sub plots. The experiment was laid out in split plot design with three replications on silt loam soils having low organic carbon (0.43 %) and nitrogen (160 kg ha⁻¹), medium in phosphorus (16.50 kg ha⁻¹) and potassium (260.0 kg

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

ha⁻¹). Results of the experiment revealed that growth contributing characters viz., plant height (cm), number of tillers m⁻², dry matter accumulation (g m⁻²), leaf area index, and yield attributes like number of panicles m⁻², length of panicle (cm), number of grains panicle⁻¹, test weight (g), grain and straw yield (q ha⁻¹) of rice were significantly higher under SRI method (M2) as compared to other methods of establishment. The growth characters like plant height (cm), number of tillers m⁻², dry matter accumulation (g), LAI and yield attributes like number of panicle m⁻², length of panicle, test weight (g), grain and straw yield (q ha⁻¹) of rice were significantly higher under 160 kg N ha⁻¹ being at par with 120 kg N ha⁻¹ and found to be significantly superior over other nitrogen levels. Test weight (1000- grain weight) was not influenced significantly due to methods of establishment and nitrogen levels.

Key words: SRI method, LAI,

EFFECT OF DIETARY SUPPLEMENTATION OF NEEM LEAF MEAL ON GROWTH PERFORMANCE OF VANARAJA CHICKS

PRAMOD KUMAR*, R.K.ASTHANA, PRAMOD PRABHAKAR, PARAMJEET PRABHAKAR*****

Dr. Rajendra Prasad Central Agricultural University, Pusa, Samastipur, Bihar - 848 125

Ten weeks feeding trial was conducted to evaluate the effect of neem (*Azadirachta indica*) dried leaf meal supplemented diet on growth performance of Vanaraja chicks. One hundred fifty growing chicks of Vanaraja birds were randomly divided into 15 separate floor pens each comprising of 10 chicks in three replication groups following completely randomised design. Five rations were formulated to contain dried neem leaf meal at 0, 1.25, 2.50, 5.00 and 10.00 percent of ration. Feed intake was measured daily and chicks were weighed weekly. Feed and water were given *ad-libitum*. Performance records and mortality percentage were measured. The significance differences in feed consumption and final body weight ($p < 0.05$) were observed among five treatment groups. There was no significant difference were in BW and FCR when chicks fed diet 0, 1.25 and 2.50 % of leaf meal. On 71st day two birds from each pen were slaughtered to analyse haematological profile (PCV, RBC, Hb, Serum and tissue cholesterol). Bird fed 5% neem leaf meal supplemented diet shows better haematological parameters in PCV, RBC and Hb. Also, supplementation of dried neem leaf meal at 5% and 10% of diet shows significant effect ($p < 0.05$) on decreasing mortality over control group. Serum and tissue cholesterol level significantly decreases ($p < 0.05$) with increasing level of neem leaf meal. The result of this investigation shows that supplementation of neem leaf meal up to 5% of dietary level can be used as growth promoter in Vanaraja chicks and could be sale early for meat purpose.

Key word: *Neem, Leaf meal, Haematological profile, Vanaraja Chicks*

CHANGES IN PHYSICAL PROPERTIES DURING NORMAL AND MODIFIED VERMICOMPOSTING OF DIFFERENT ORGANIC RESIDUES

PRANETI H. SONAWANE, SHAILESH V. AHIRE AND JAYESH P. PATIL

Department of Soil Science and Agricultural Chemistry, College of Agriculture, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani-431 402 (M. S.), India

The experiment was laid out in factorial randomized block design with Four treatments (sugarcane trash, soybean straw, vegetable market waste and sugarcane trash + soybean straw) and three replications for both of the method (Normal vermicomposting M₁ and Modified vermicomposting M₂). During vermicomposting period, the samples were collected at an interval of 15 days. i.e. 15th, 30th, 45th, and 60th day's interval. In normal vermicomposting black colour indicated in vegetable market waste, very dark brown in soybean straw, dark grey in sugarcane trash and very dark brown in sugarcane trash + soybean straw. While in case of the modified vermicomposting black colour of vermicompost indicated in vegetable market waste, very dark grey in soybean straw, very dark grey in sugarcane trash and very dark grey in sugarcane trash + soybean straw. The result indicated that the physical properties like temperature and porosity was recorded significantly higher in normal vermicomposting (M₁) than modified vermicomposting (M₂) at 15 to 60 days. In treatment the maximum reduction of temperature was recorded with vegetable market waste (T₃) 24.83°C over to soybean straw (T₂) 27.17°C, sugarcane trash + soybean straw (T₄) 27.67°C and sugarcane trash (T₁) 28.67°C at all days. The lower value of porosity was recorded 67.54 to 63.39 % with vegetable market waste (T₃) at 30 to 60 days of vermicomposting than the other treatments. The high value of bulk density (Mg m⁻³) was recorded in modified vermicomposting (M₂) over to normal vermicomposting (M₁) at 30 to 60 days. In vermicomposting with vegetable market waste (T₃) was highest bulk density recorded (0.97 Mg m⁻³) at 60 days.

ROOTSTOCK TRANSFORMATION: STRATEGY TO MITIGATE THE VARIOUS STRESSES IN FRUIT CROPS

PRASHANT KALAL¹, SAJANAS.¹, PARVATHI BENNURMATH²

¹*Division of Fruit Crops and* ²*Division of Floriculture and Medicinal Crops, ICAR-Indian Institute of Horticultural Research, Bengaluru-560089*

Fruits are the source of vitamins, micronutrients and play an important role in the nutritional security. The extending area under fruit

cultivation with an efficient utilization of degraded and affected land in order to enhance per capita availability of fruits. The several biotic and abiotic stresses such as salinity, drought, frost, insect-pest and diseases etc. hinders an establishment of a fruit orchard in the stress-prone area thereby greater reduction in the total fruit yield and productivity. The strategies of conventional rootstock breeding often more time consuming, labor intensive and expensive. Genetic engineering as an alternate approach to make breeding faster, more specific and economical. The development of resistant rootstocks through *Agrobacterium*-mediated and particle bombardment transformation with the intention of silencing stress causing genes. The non-transformed desirable fruit variety used as scion for grafting on genetically modified rootstock. There is no any modification in the genetic of scion after grafting on transformed rootstock. The normal transportation of water, sugar and other metabolites including small molecules of RNA except DNA from the GM-rootstock into the non-GM scion variety. Even though there is no alteration in the DNA of the scion by the transformed rootstock. Those transported molecules from the rootstock can influence the expression of specific genes in the scion which are responsible for stresses in a specific manner. The transformed rootstocks for grafting has been adopted in some regions of the world in some fruit crops like apple, peach, grape and walnut etc. The studies on the feasibility of rootstock transformation against specific stress in other commercial fruit crops are needed.

TRADITIONAL KNOWLEDGE AND ETHNOBIOLOGY

PRATISTHA PRADHAN AND GAVASKAR

Department of soil science and agricultural chemistry, Sam Higginbottom University of Agriculture, Technology and Sciences, Naini Agricultural Institute, Allahabad 211007

This paper involves the portrayal of how traditional knowledge is important in agriculture and how its adaptation with recent trends can prove beneficial in maintaining the social and economic sustainability of the environment. It asserts that an understanding of indigenous practices of cultivation along with the scientific study about the behaviour of the farmers can offer huge potential for revolutionizing the manner in which the agricultural sector in our country operates. Since the majority of Indian farmers are not very accepting of change to modern practices, the utility of Ethnobiology to overcome the barrier can be made. Ethnobiology is the study of biological knowledge of particular ethnic groups cultural knowledge about plants and animals and their interrelationships. Traditional knowledge is emerging as important, even necessary, for managing key resources and ecosystem. Most of the knowledge is learned long ago and passed on to generations but Ethnobiological knowledge is subject to change since our environment is dynamic. The combination of religious practices, myths and spiritual beliefs all render the traditional practices not as a science, yet, this aspect has significance which is why the topic is of utter interest among recent scholars. There is a desperate need to record knowledge that is being forgotten due to adoption of modern practices that are not completely beneficial to agriculture. Thus, Ethnobiology is a major part of the ongoing effort to save these natural and human worlds and reduce the dominance of technology.

Keywords :- Ethnobiology, sustainability, indigenous knowledge, environment.

GENETIC VARIABILITY STUDIES IN CLUSTER BEAN [*CYAMOPSIS TETRAGONOLOBA* (L.) TAUB]

PRAVEEN CHOYAL¹, RAHUL KUMAR BYADWAL² SANDEEP KUMAR³ AND KALYAN SINGH SEERV⁴

^{1,2}SKN College of Agriculture, Jobner, Jaipur, ³CH&F, Jhalawar, ⁴SHUATS, Allahabad (UP)

An present investigation was carried out at Horticulture Research Farm, Department of Horticulture, Naini Agricultural Institute, Sam Higginbottom University of Agriculture, Technology and Sciences Allahabad during during Kharif 2016-17. Fifteen genotypes of cluster bean [*Cyamopsis tetragonoloba* (L.) Taub] were evaluated to estimate variability, broad sense heritability and genetic advance over mean for vegetable pod yield and related attributes. Maximum range of variability was observed for plant height 90 days (cm), number of branches 90 days, fruit clusters per plant, pod/plant, pod yield per plant (g) and pod yield/ha (q). High heritability coupled with high genetic gain in percentage was observed for all studied traits excepted days to 1st flowering, days to 50% flowering, days to 1st pod picking, pod width, pods/cluster. Showed high genotypic coefficient of variation as well as high phenotypic coefficient of variation was recorded for number of branches/plant 45 days while recorded minimum for days to 1st pod picking. The results of present investigation suggested that selection based on plant height 90 days (cm), number of branches 90 days, fruit clusters per plant, pod/plant, pod yield per plant (g) and pod yield/ha (q) might bring simultaneous improvement in vegetable pod yield of cluster bean.

Keywords: Cluster bean, genotypic coefficient, phenotypic coefficient of variance, heritability and genetic advance

EFFECT OF LEVELS OF POTASSIUM AND IRRIGATION ON YIELD, TUBER QUALITY AND WATER USE EFFICIENCY

PREM CHAND KUMAR¹ AND MUKESH KUMAR²

¹Department of soil science & Agricultural chemistry, B.A.U. Sabour Bihar, ²Department of Soil Science, R.A.U. Pusa Bihar

Potato is grown usually on the moisture stored in soil during preceding rains and as such the crop suffers from frequent moisture stress

condition. Under such condition it becomes imperative to utilize water efficiently and to improve the water use efficiency of the crop with improved yields. Thus, optimum use of water and potassium is needed for improved yield and quality of potato. Experiments were conducted at water management field of Rajendra Prasad Central Agricultural University, Pusa (Samastipur), Bihar on calcareous sandy loam soil, alkaline in nature having pH 8.5, low nitrogen, phosphorus and potassium in split plot design, replicated thrice to evaluate the performance of potato on four levels of irrigation on the basis of IW/CPE ratio (I_1 , I_2 , I_3 and I_4 i.e., 0.6, 0.8, 1.0 and 1.2, respectively) in main plots and five levels of potassium (K_0 , K_1 , K_2 , K_3 and K_4 i.e., K_2O @ 0, 50, 100, 150 and 200 kg ha⁻¹) in sub plots. Yield, tuber quality and water use efficiency were studied. I_4 level of irrigation improved the potato tuber yield by 16.43 and 17.65 per cent over I_1 similarly K_3 level of potassium improved the tuber yield by 22.88 and 29.20 per cent over control (K_0) 1st year and 2nd year, respectively. I_4 level of irrigation was found the best for all quality parameters like reducing sugar, starch content, T.S.S., specific gravity and crude protein. For crude protein and reducing sugar K_3 level was found the best while K_4 level for starch, T.S.S. and specific gravity. The highest value of water use efficiency was recorded with I_2 level of irrigation. Increasing levels of potassium significantly improved the water use efficiency up to K_3 level of potash application during both years.

Key Words : Potassium , Irrigation, Tuber quality ,water use efficiency

EFFECT OF NPK ON PLANT YIELD AND QUALITY OF CAPSICUM (*CAPSICUM ANNUM* L.) C.V. YOLO WONDER UNDER SHADE NET CONDITION.

PREM KUMARIAHEER, A. RAJPUROHIT, KOMAL BHADALA, G. S. DEORA, A.K. PANDEY, DIVYARAJPUT*, ARCHI GUPTA*

*Bhagwant University Ajmer, *SVPUAT Meerut U.P.*

A field experiment was conducted to study of "Effect of NPK on Plant Growth, Yield and Quality of Capsicum (*Capsicum annum* L.) c.v. Yolo Wonder Under Shade Net Condition" during *Rabi* season (October to March) in the year 2017-18 of the Department of Horticulture, at Faculty of Agriculture, Bhagwant University Ajmer under semi arid eastern plains. The experiment consists of 9 treatment viz, There were 9 treatment viz T_1 , T_2 , T_3 , T_4 , T_5 , T_6 , T_7 , T_8 , T_9 laid out in Randomized Block Design with three replications. The treatment combination of N.P.K. T_7 (160:60:50 kg/ha) found superior overall other treatments in relation to growth parameters but low in production and quality, N.P.K. T_5 (160:70:50 Kg./ha) found superior in terms of yield and N.P.K. T_6 (150:60:50 kg/ha) was superior in relation to quality (fruit length, fruit diameter, shelf life, TSS) of capsicum. Maximum T_5 Number of Fruit/Plant, fruit yield per plant (kg), fruit yield (kg)/green house (8.70), (1.99kg), (321.84kg) and T_6 fruit length (9.61cm), fruit diameter (8.01cm), TSS (5.82°B), Shelf life (7.60 days) fruit weight (gm.) (230.99gm). T_5 was found to be most viable economically in terms of net returns, and Cost of benefit ratio (7069554Rs/ha & 1:3.18). Thus, application of optimum doses of NPK was found highly beneficial for plant growth, yield and quality of capsicum.

Keyword: Capsicum, NPK, Growth parameter, yield, TSS, Shelf Life.

EFFECT OF ORGANIC MANURE AND INORGANIC FERTILIZERS ON MAIZE PRODUCTION

PREM SINGH, U.P. SHAHI AND SANJAY KUMAR

Department Soil Science and Agril. Chemistry S.V.P.U.A. & T Meerut (U.P.) India

It is one of the most important cereal crop, that allow the food self-sufficiency program of the country, playing a key role in the human diet and animal feed, providing adequate amounts of energy and protein. Being the exhaustive crop, maize requires large amount of nutrients particularly N for producing more yield. Depletion of soil organic matter (SOM) and plant nutrients lead to reduction in soil fertility and productivity. This problematic situation is aggravated by continuous cultivation on crop with the mismanagement of nutrient sources, especially mineral fertilizers resulting in imbalanced soil nutrient status. The quality protein maize is low due to inherent low soil fertility and poor nutrient management practices like low use of inorganic fertilizers, no use of organic manures, poor recycling of crop residue and no use of secondary and micronutrient. In maize cultivation, the farmers are giving much attention only to N fertilization and very often P and K applications are carried out at minimal level, mostly missing K fertilization. The SSNM approaches not only aim to reduce or increase fertilizer use, it is also effective tools for supplying crop nutrients and to achieve higher yield, besides this it also aims to increase nutrient use efficiency, leading to more net returns per unit of fertilizer invested.

MECHATRONICS DRIVEN SEED METERING MECHANISM IN PRECISION PLANTING

PREM VEER GAUTAM^{1*}, HARILAL KUSHWAHA² AND PRABHAKAR SHUKLA³

^{1,3}ICAR-CIAE, Nabi Bagh, Bhopal-462038, ²Agricultural Engineering, IARI, New Delhi.

Mechatronics basically refers to mechanical electronic systems and normally described as a synergistic combination of mechanics, electrical, electronics, computer and control. When these are embedded makes possible the generation of simple and reliable systems

such as precision sowing technologies. Precision planting is a prerequisite for mechanized cultivation and its importance in efficient land use. Conventional planters have problems of ground wheel skidding and vibration in the mechanical transmission system which affect desired seed spacing. This opens new innovative ways of cultivating that allows farmers to quality of planting without losing seed, accuracy and time. The mechatronic driving system performed better than the mechanical driving system both on tilled and non-tilled fields. The control system could make the seed-metering device synchronized with the working speed of the planter so as to reduce seeding non-uniformity caused by ground wheel's slipping. It was observed that as the working speed increased, quality of feed index (QFI) of the seed-metering device dropped gradually with increased miss index (MI) and precision index (PI) as well as deviation from the average seeds spacing became greater. The studies were indicated that pneumatic planter equipped with mechatronics system observed good seeding uniformity among all seeding technologies. Thus, mechatronics metering mechanism may be one of the options to achieve accurate seed spacing with higher efficiency in order to reduce the effect of forward speed.

Keywords: Precision, Synergistic, Sensor, Mechatronics, mechanized.

EFFECT OF WEED MANAGEMENT ON SOIL MICRO FLORA IN SPRING SEASON SWEET CORN (*ZEA MAYS* L. SACCHARATA) IN TARAI REGION OF UTTARAKHAND

PRITHWIRAJ DEY*, TEJ PRATAP

Department of Agronomy, G.B. Pant University of Agriculture & Technology, Pantnagar

A field experiment was conducted in the spring season of 2017 in sweet corn crop to evaluate different weed control methods and to find out the best weed management practice with the lowest impact upon soil health. Effectiveness of weed control measures were evaluated on the basis of weed control efficiency on the basis of total accumulation of weed dry matter. The highest weed control efficiency was recorded in hand weeding twice at 20 and 40 DAS which was closely followed by pre-emergence application of atrazine 1000 g/ha followed by sequential application of tembotrione 120 g/ha. The lowest set of values of soil dehydrogenase activity was recorded from pre-emergence application of atrazine at 1000 g/ha alone and in combination with other weed control measures suggesting an overall negative impact of atrazine upon the soil microbial activity. Pre-emergence application of atrazine 1000 g/ha was found to have detrimental effects upon soil micro flora as indicated from the decline in soil dehydrogenase activity. However application of tembotrione alone as post emergence 120 g/ha was having very low impact upon soil micro flora on the basis of soil dehydrogenase activity with an appreciable weed control efficiency. The study also indicated about the time that a healthy soil needs to recover from the damage caused to the soil micro flora by application of different chemicals. Continuous use of atrazine 1000g/ha as soil application without proper allowance time for the soil micro flora to come back to its original state after the damage has been caused, should be strictly avoided from soil and environmental health point of view. Manual weeding and use of less toxic foliar applied herbicides like tembotrione 120 g/ha and halosulfuron-methyl 90g/ha as post emergence application may be used as options for effective weed control in spring sweet corn crop profitably without deteriorating soil biological health especially.

EFFECT OF CHEMICAL FERTILIZERS AND BIOFERTILIZERS ON NORMALIZED DIFFERENCE VEGETATION INDEX (NDVI) IN BARLEY CROP

PRITI MALIK, MEENASEWHAG AND KARMAL MALIK

Department of Agronomy, CCS Haryana Agricultural University, Hisar, Haryana, India-125004

Barley (*Hordeum vulgare*) is fourth most important cereal crop in the world after wheat, rice and maize having share of seven percent of the global cereals production. It can be successfully grown in adverse climatic conditions of drought, salinity and alkalinity. An experiment was conducted during *rabi* 2015-16 and 2016-17 at Agronomy Research Area of CCS Haryana Agricultural University, Hisar, Haryana (India) situated at 29°10' N latitude and 75° 46' E longitude at an elevation of 215.2 m above mean sea level to study the response of barley to fertilizer levels and different combinations of biofertilizers. The experiment was laid out in a split plot design with three fertilizer levels (50, 75 and 100 % RDF) in main plots and seven different combination of biofertilizers (Uninoculated, Seed inoculation with *Azotobacter*, Seed inoculation with *Azospirillum*, Seed inoculation with PSB, Seed inoculation with biomix, Seed inoculation with *Azotobacter*+PSB and Seed inoculation with *Azospirillum* +PSB) in sub plots replicated thrice. Based on the research investigation it was found that NDVI value of barley at all the stages of crop growth increased significantly with increase in fertilizer levels during both the years of experimentation. But, the NDVI value of barley with the application of 75% RDF was at par with application of 100% RDF at all the stages of crop growth. However, in the year 2016-17 the difference in NDVI value of barley at anthesis stage was significantly higher with the application of 100 % RDF as compared to 75 % RDF. Various combinations of biofertilizers inoculation failed to influence NDVI value of barley at all the stages of crop growth.

Keywords: biomix, NDVI, *Azospirillum*, *Azotobacter*, PSB

EFFECTIVE USE OF NITROGEN FIXING WATER FERN AZOLLA AND ANABENA IN RICE CROP**PRITISHREE BHOI¹ AND DEBASHIS NAYAK²***1: Gandhi Institute of Biological sciences, Berhampur University, Gunupur, Rayagada, Odisha, 2: Dept. of Agronomy, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha*

Agriculture is one of the most important factors contributing to the economic growth of India. Out of the 329 million hectares of India's geographical area, about 114 million hectares are under cultivation. In order to reap a better harvest, farmers inoculate the soil with fertilizers. Fertilizers come in two types they are either chemical or biofertilizers. Increasingly high inputs of chemical fertilizers during last 150 years have not only left soils degraded, polluted and less productive but have also posed severe health and environmental hazards. Organic farming methods (such as the use of biofertilizers) would solve these issues and make the ecosystem healthier. Ability of Azolla-Anabaena system to fix atmospheric nitrogen at faster rates makes it an outstanding agronomic choice for the cultivation of rice under tropical conditions. Nitrogen fixation potential of the Azolla-Anabaena system has been estimated to be 1.1 kg N ha⁻¹ day⁻¹ and one crop of Azolla provided 20-40 kg N ha⁻¹ to the rice crop in about 20-25 days. Azolla has been known to influence the dynamics of the total soil and microbial population of nitrogen fixing bacteria. The soil fertility index will improve due to the accumulation soil enzymes. Therefore we need to have efficient strains of Azolla to maintain the soil fertility.

Keywords: Azolla, Nitrogen fixing bacteria and soil fertility.

IMPORTANCE OF VALUE ADDITION IN HORTICULTURE CROPS**PRIYANEGI¹ AND RAJ BALACHOUDHARY²***Department of Horticulture, Sri Karan Narendra Agriculture University, Jobner, Jaipur (Raj.) 303329*

Fruits and vegetables are highly perishable but most important commodity for human diet due to their high nutritional value. Fruit and vegetable are available in surplus only in certain seasons and availability in different regions. In peak season due to improper handling practices, marketing, storage problems around 20-25% fruit and vegetable are spoilt in various stages. They are the cheapest and other source of protective food supplied in fresh or processed or preserved form throughout the year for human consumption. Hence, proper postharvest management handling and processing is required in horticulture crops. To make foods available throughout the year, humans have developed methods to prolong the storage life of products, that is, value addition by preserve them. The technology has become a necessity to improve the food safety and strengthen nation's food security. The technology helps to boost export of horticultural commodities in the form of preserved and value added products. Preservation helps the farmers to obtain a better return by checking wastage during a market glut. It keeps the products in proper condition, which is not possible under ordinary or cold storage conditions. hence, preservation is suitable substitute for storage. It allows fruits and vegetables to be available during off seasons and in locations where these are not grown. One of the main difficulties in the path of the growth of the fruit and vegetable industry has been the inadequacy of knowledge of the modern methods and techniques of preservation. So, to overcome these difficulties various aspect of the importance of various preservation methods and limitations to be considered during preservation of fruits and vegetables.

Keywords: value addition, preservation, post harvest, horticulture crops.

SECONDARY METABOLITES OF MICROBIALS AS POTENTIAL SOURCE OF AGROCHEMICALS**PRIYASINGH***Department of Plant Pathology, College of Agriculture, G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand*

Indiscriminate use of pesticides over last four to five decades have led to development of resistance in plants and accumulation of toxic residues in the environment, leading to serious health hazards. Use of microbial secondary metabolites is an alternative strategy for pest management. Microbial pesticides comprise of microorganisms such as fungi, bacteria, viruses and actinomycetes. They produce mixture of structurally related compounds called as secondary metabolites which have no role in their growth and development. The natural products of microbial origin are categorised as Bactericides, fungicides, insecticides, herbicides and nematocides. The major insecticide includes Spinosads from actinomycetes, Avermectins and milbemectins. *Bacillus thuringiensis* and *Photobacterium luminescence* are potential insecticides. The toxin produced by *Bacillus thuringiensis* is effective against wide range of insects including Lepidoptera, Diptera and Coleoptera. Bialaphos and Vulgamycin isolated from actinomycetes are major commercially available bioherbicide. They can effectively control both monocot and dicot weeds. Fungicides and bactericides of microbial origin comprise of Strobilurins, Blastocidin, Kasugamycin, Vallidamycin which are effective against *Venturia inaequalis*, *Cercospora arachidicola* and *Phytophthora infestans*. According to Business Communication Company (BCC) the total global market for microbes and microbial products was estimated at nearly \$143.5 billion in 2014 and is expected to reach nearly \$306 billion at a compound annual growth rate (CAGR) of approximately 14.6% over the period from 2015 to 2020 (Microbial products 2015). Pesticide based on micro-organisms are proven to be highly effective. Being ecofriendly, less hazardous to non target pest, these microbial pesticides emerges as potential option for pest management and there is ample scope for further development in agriculture.

INFLUENCE OF FOLIAR APPLICATION OF NUTRIENTS ON FLOWERING, FRUITING CHARACTERISTICS AND YIELD OF GUAVA (*PSIDIUM GUAJAVA*) CV. L-49**PRIYA YADAV, J.R. SHARMA, RUPAKSHI AND SATPAL BALODA***Department of Horticulture, CCS Haryana Agricultural University, Hisar*

In depth study focusing to ascertain the effect of foliar sprays of ZnSO₄ (0.50, 0.75 and 1.00%), FeSO₄ (0.2, 0.4 and 0.6%), K₂SO₄ (0.5, 1.0 and 1.5%) and Urea (1.0, 1.5 and 2.0%) along with control (water spray) before flowering and after fruit set, during rainy and winter seasons, in improving the flowering, fruiting characteristics and yield of guava (*Psidium guajava* L.) cv. L-49 was carried out in the Experimental Orchard of Department of Horticulture, CCS Haryana Agricultural University, Hisar during 2016-17. The findings of the experiment revealed that the foliar application of various nutrients significantly increased the flowering and fruiting characters of the plants over control. Maximum number of flowers per branch (19.66 and 14.74), fruit set (61.17 and 70.24%) and yield per plant (32.76 and 29.31 kg/tree) were recorded with minimum fruit drop (19.52 and 14.27%) under the treatment ZnSO₄ @1.00 per cent, during rainy and winter seasons, respectively. Application of ZnSO₄ @0.75 per cent was also found to be equally good, during both the seasons of investigation.

Key words: Nutrients, foliar spray, guava, growth, yield.

EFFECT OF BIOFERTILIZERS ON GROWTH AND YIELD OF OKRA (*ABELMOSCHUS ESCULENTUS* L.)**PRIYANKA GURJAR¹, R.S. GURJAR² AND J.S. GURJAR³***1. College of Agriculture, RVSKVV GWALIOR, 2. BRAUSS, Mhow, M.P., 3. M.G.C.G.V., Chitrakoot, Satna M.P.*

Okra (*Abelmoschus esculentus* L.) is one of the most important vegetable crops belongs to malvaceae family being grown all over the country. Okra is an economically important vegetable crop grown in tropical and subtropical parts of the world. Okra is a multipurpose crop due to its various uses of the fresh leaves, buds, flower, pods, stems and seeds. Okra immature fruits which are consumed as vegetables, can be used in salads, soups and stews, fresh or dried, fried or boiled. Raw okra is 90% water, 2% protein, 7% carbohydrates and negligible in fat. In India okra is grown in 501.02 lakh hectare areas and its production is 5972.23 MT (2017-2018). This experiment was conducted college of Agriculture gwalior during the rabi season of 2017 - 2018 to study the "Effect of Biofertilizers on growth and yield of okra c.v Pusa Sawani. The experiment comprised of biofertilizer viz. Azospirillum and AMF with 4 levels of recommended dose of fertilizer 25, 50, 75, 100% were tested in comparison with control (no fertilizer and chemical fertilizer). The experiment was laid out in RBD (Randomized block design) with 9 treatments replicated thrice. Based on the results, it could be concluded that the application of biofertilizers Azospirillum + AMF + 75% RDF could increase the growth, yield and yield components of okra.

FOOD PROCESSING AND VALUE ADDITION IN HORTICULTURAL CROPS**PRIYANSHU SINGH, PH.D. RESEARCH SCHOLAR (DEPT. OF HORTICULTURE)***Institute of Agricultural Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh- 221005*

The purpose of traditional food processing is preservation to maintain a supply of wholesome, nutritious food during the year and preservation for the time of scarcity. While food processing still has the main objective of providing a safe nutritious diet in order to maintain health, other aspects, particularly the generation of wealth for the producer and seller, have become increasingly important. The increasing number of women who now work away from home adds additional pressure for such changes. Even people with a heavily traditional diet are demanding external products either as occasional treats such as gassy drinks, or basic commodities such as white sugar and flour. One of the major problems in horticultural sector is value addition of raw products by processing as horticultural crops are perishables. On average less than one percent of vegetables produced are processed as most of the processing takes place by the traditional method and for the traditional use as results vegetables are processed at the very small scale. The goal of the project is to improve livelihood opportunities through vegetable processing. The objectives of the project was value addition in fresh leafy vegetables by processing through solar drying method; upgrade the technical knowledge and skills of improved vegetables processing techniques, and increasing food security in the community. The findings include the fact that leafy vegetables losses is very high as majority of community members lack knowledge and technical skills in food processing, lack of market for processed vegetables and inadequate capital for investment. However, the income generating activity identified to improve livelihoods was leafy vegetables processing by solar dryer method. Vegetable processors group implemented the project which was designed based on the specified objectives. Participatory monitoring and evaluation realized project output at 86.4% for the enhancing knowledge of vegetables processing techniques.

Keywords: solar dryer method, food processing, participatory monitoring and evaluation

THEME: ENVIRONMENTAL AND LIVELIHOOD SECURITY FOR SUSTAINABLE DEVELOPMENT

STUDY OF DISSIPATION BEHAVIOR OF MALATHION IN CABBAGE

Purti, R. S. Jaglan and Krishna Rolania, Department of Entomology, CCS Haryana Agricultural University, Hisar, Haryana-125004, INDIA

A field experiment was conducted at research farm of Department of Entomology, CCS HAU, Hisar during the 'rabi' season of 2017-2018 to study the dissipation behavior of malathion 50 EC @ 1L/ha in cabbage samples. Malathion was applied as foliar spray at the recommended dose @ 1L/ha and double of the recommended dose @ 2L/ha at the head formation stage to control the different insect-pests of cabbage. For the analysis of residues of malathion in cabbage the samples were picked at 0 (1hr), 3, 5, 7, 10 and 15 days of application of insecticide. Samples were carried out in residue analysis laboratory, Department of Entomology, CCS HAU, Hisar. Samples were **extracted and cleaned up by using liquid-liquid partitioning method**. Residues of malathion in cabbage was analyzed by using the Gas Chromatography System. Half life period of malathion was 1.18 days at the recommended dose and 1.0 day at double of the recommended dose in cabbage. Residues of malathion was dissipated up to 86.76% on 7th day after spray and reached below detectable limit (BDL) of 0.05 mg kg⁻¹ on 10th day at the recommended dose @ 1L/ha. Furthermore, at the double of recommended dose of @ 2L/ha residues of malathion was dissipated up to 93.38% on 7th day and 96.61% on 10th days after spray.

Keywords: Dissipation, Malathion, Cabbage, GC, Half-life

SOIL AMENDMENTS FOR IMPROVING CROP YIELD IN SALT AFFECTED SOILS

*PUSHPALATHA, M., SUNIL, B. H. AND PARAMESHWARAREDDY, R.

* Department of Soil Science and Agricultural Chemistry, UAS Dharwad, Division of Soil Science and Agricultural Chemistry, ICAR-Indian Agricultural Research Institute, New Delhi, Department of Agronomy, UAS Dharwad

Soil amendment are improving the crop yield in salt affected soils. Sodic and alkali soils are characterized by the occurrence of excess sodium (Na⁺) and salts of sulphate, chlorides, carbonates and bicarbonates etc., are adversely affect soil structure and disturb the availability of nutrients for plant growth. Increasing the productivity of water and making safe use of poor quality waters in agriculture will play a vital role in easing competition for scarce water resources, prevention of environmental degradation and provision of food security. Driven by the pressure to produce more, even the saline and alkali waters are being increasingly diverted to irrigated agriculture. Development of salinity, sodicity and toxicity problems in soils not only reduces crop productivity and quality but also limit the choice of crops. Major production constraints of Saline soils exit in arid and semi-arid region, such soils are poor physical properties- high ESP, dispersion of fine clay- (high Na), low permeability impeded aeration, soil water movement, poor aggregate stability, low organic matter content, reduced availability of N, K, Zn, Fe etc. this is cause reduction in crop yield mainly due high concentration of soluble salts in soil, salt toxicity, and their management strategies include leaching and drainage methods. Such a way sodic soil are contributing the same problems in crop production like hard pan formation and reduces the infiltration capacity, hydraulic conductivity etc., Management strategies of alkali/sodic soil include leaching, crop establishment, crop choice, organic and inorganic amendment. Application of gypsum based on the gypsum requirements (GR) varied from 8.5 to 15.5 t ha⁻¹ is considered as one of the most useful strategies to reclaim alkali/sodic soils. Cultivation of salt tolerant crops (barley, sugarbeet, cotton), grasses (karnal grass, para grass, bermuda grass) and tress (date palm, eucalyptus, acacia) increase the productivity but also improve the soil physico-chemical properties. These approaches help for enhancing the crop yield.

EVALUATION OF DIFFERENT GENOTYPES OF CROSSANDRA (CROSSANDRA SPP.) IN RESPECT OF GROWTH AND FLOWERING ATTRIBUTES

PUSHPANJALI BHOSALE¹, M. B. KADAM², VAIBHAV WADEKAR³ AND NAGESH GAWADE⁴

¹ & ³ College of Agriculture, Pune-05, MPKV, Rahuri, ² Assistant Professor of Horticulture, NARP, Ganeshkhind, Pune-7, ⁴ Junagadh Agricultural University, Junagadh-362001

The present investigation was conducted at AICRP on Floriculture, National Agricultural Research Project Ganeshkhind, Pune7, MPKV; Rahuri, during 2015-2016. The experiment was laid out in randomized block design with three replications and seven genotypes. At 60 days after planting, the genotype Arka Ambara recorded significantly maximum plant height. At 120 and 180 days after planting, the genotype Local-2 recorded significantly maximum plant height. The number of branches at 180 days after planting, the genotype Local-1 recorded significantly maximum number of branches (32.15) which was at par with Local-2 (28.60) and Arka Kanaka (26.01). The spread of plant (N-S) at 60, 120 and 180 days after planting was significantly maximum Local -1. The plant spread (E-W) direction at 60, 120 and 180 DAP was significantly maximum in genotype Local-1 (44.76 cm) which was at par with Arka Shrvya. Arka Shrvya was significantly superior over all genotypes, which recorded least days for flower initiation, rachis length and spike length which was at par with Arka Kanaka. Variety Arka Ambara was significantly superior over all genotypes, which was significantly superior over all genotypes, which recorded floret length and width which was at par with Arka Kanaka.

Key words: Crossandra genotypes, growth and flowering attributes.

CHITOSAN COATING AFFECT THE SHELF LIFE AND QUALITY OF PLUMS DURING LOW TEMPERATURE STORAGE

PUSHPENDRAKUMAR*, SHRUTISETHI AND R.R. SHARMA

Division of Food Science and Postharvest Technology, ICAR-Indian Agricultural Research Institute, New Delhi, India

Plums are one of the important temperate fruit crops in India but the fruits are highly perishable and have a very short shelf life. The combined effects of chitosan and low temperature storage on the shelf life and quality maintenance of fresh plums (*Prunus salicina* Lindley, cv. 'Santa Rosa') were investigated. The plum fruits were coated with 2.0 % chitosan coating and then stored at 1 ± 1 °C and 90/95 % Relative Humidity. The chitosan coating significantly reduced the fruit firmness and weight loss, delayed changes in pectin methylesterase activity and malondialdehyde contents and inhibited the loss of soluble solids content, titratable acidity, ascorbic acid, total phenol and antioxidant activity during 35 d of storage. The coating was also shown to be very effective in inhibiting the ethylene evaluation, respiration rate compared to the control samples at 1 ± 1 °C. In addition, the 2.0 % chitosan coated plum was firmer and showed less peel colour change than the uncoated samples at the end of storage. During storage, anthocyanin synthesis was significantly inhibited with the combination of chitosan and low temperature. The results of our study revealed that the 2.0 % chitosan coating showed good potential to enhance the storage life of plums during cold storage.

PHENOLOGICAL AND MORPHOLOGICAL BEHAVIOUR OF PARENTS AND IT'S HYBRID SEEDLINGS IN PEACH [*PRUNUS PERSICA* (L.) BATSCH]

PUSHPENDRA RAJPUT¹, ANIRUDH THAKUR², JAGVEER SINGH³, KULDEEP PANDEY⁴ AND RAJAT SHARMA⁵

^{1,5}Department of Horticulture, Collage of Agriculture, G. B. Pant University of Agricultural and Technology, Pantnagar, Uttarakhand 263145, ^{2,3}Department of Fruit Science, Punjab Agricultural University, Ludhiana 141004, ⁴Department of Fruit Science, Indian Agricultural Research Institute, New Delhi 110012

The F1 hybrid seedlings developed from different cross combination of two peach 'Sharbati' and 'Flordaguard' and one plum 'Kala Amritsari' during 2017 and 2018. The earliest flowering was noted in Sharbati then Flordaguard and Kala Amritsari. Flowering of Sharbati and Flordaguard coincide very well for hybridization. In control pollination highest fruit set percent was recorded in Sharbati × Flordaguard (36.40%) and minimum in Kala Amritsari × Flordaguard (17.28%). Highest fruit retention was recorded in Flordaguard × Sharbati (40.38%) and minimum in Sharbati × Kala Amritsari (4.58%). The maximum days from full bloom to maturity were taken in Flordaguard × Sharbati (128 Days) and minimum in Kala Amritsari × Flordaguard (111 Days). Fruits of Kala Amritsari × Flordaguard were mature earliest (8th-12th May) and latest in Flordaguard × Sharbati (20th-28th June). The highest pollen viability in case of stored as well as fresh pollen respectively, was recorded in Flordaguard (96.26 and 97.58%) while, minimum in Sharbati (90.89% and 96.60%). Seedlings of Sharbati, Sharbati × Flordaguard and Flordaguard × Sharbati showed better growth performance on Flordaguard seedlings. The colour of newly developed leaves of Sharbati and Kala Amritsari were dark green on the upper surface and light green in lower surface. The leaves of Flordaguard and both the hybrids (Sharbati × Flordaguard and Flordaguard × Sharbati) showed dark reddish to purplish green colour on upper surface and light reddish green in lower surface of leaves. The hybrid seedlings from both the crosses showed the dominant red leaf colour of Flordaguard.

SUSTAINABLE HORTICULTURE PRODUCTION

PUSHPENDRA SINGH¹, ABHITEJ SINGH SHEKHAWAT², HITESH AGARWAL¹ AND RAMESH CHAND CHOUDHARY¹

¹Department of Horticulture, Rajasthan College of Agriculture, MPUA&T, Udaipur, India, ²Department of Soil Science & Ag. Chemistry, Rajasthan College of Agriculture, MPUA&T, Udaipur, India

The stage is set for rapid expansion of vegetable production in India, which is currently insufficient to meet per capita requirements. Increased income, population growth, and fast urbanization have created additional demand for vegetables. There is need to diversify production, and forces are reinforced by consumer demand for a diversified diet. Both production- and trade-oriented strategies should be used to overcome shortage and seasonality in vegetable supplies. Production-oriented strategies should focus on developing high yielding and stress tolerant varieties and management technologies, so that more farmers can produce more vegetables at lower per-unit cost while vegetables, taking advantage of higher production and lower costs in favorable growing areas. Successful production of sufficient, good quality vegetables leads to good health, more jobs, diversified and higher incomes for producers, and long-term sustainability of the agricultural resource base. To achieve all these, however, some minimum level of farmers' education, field-market linking infrastructure, and favorable government policies to encourage and stabilize vegetable production are required. Under this scenario, technological innovation can act as a catalyst to expand vegetable production. The enhanced management capability of

vegetable-growing farmers would then enable them to actively participate in the economic development process of the whole economy.

GOOD AGRICULTURAL PRACTICES (GAP) IN PROTECTED CULTIVATION

PUSHPENDRASINGH¹, PRATISHTHA DIWAKER¹, ABHITEJ SINGH SHEKHAWAT² AND AKANSHADEORA³

¹Department of Horticulture, Rajasthan College of Agriculture, MPUA&T, Udaipur, ²Department of Soil Science & Ag. Chemistry, Rajasthan College of Agriculture, MPUA&T, Udaipur, ³Department of Plant Pathology, Rajasthan College of Agriculture, MPUA&T, Udaipur

Good Agricultural Practices (GAP) are “practices that address environmental, economic and social sustainability for on-farm processes, and result in safe and quality food and non-food agricultural products”. During 1997, to set standards for the certification of agricultural products around the globe, Euro-Retailer Produce Working Group (EUREPGAP) were initiated, which later evolved into GLOBALGAP. The four pillars of GAP are economic viability, environmental sustainability, social acceptability and food quality and safety. Greenhouse production systems require adherence to GAP protocols because exhaustive cultivation in greenhouses often involves excessive use of chemicals since the stakes are high due to intensive inputs and high expectations on quality front. Major principles of good agriculture practices that should be followed in protected cultivation include Traceability, record keeping and self-inspection, varieties and root stocks, site history and site management, Soil and substrate management, fertigation, crop protection, harvesting, produce handling, waste and pollution management, recycling and re-use, workers health, safety and welfare, environment Issues, complaint form, practicing timely operations, trenching around polyhouse, Maintaining uniform bed height, Changing of cladding material, use of pathogen, weed free manures like well decomposed farmyard manure or goat / sheep dung, planting early or lately according to market study, selection of proper varieties, avoid overaged & underaged seedlings, regular monitoring, timely fertigation, Provision of double gate on opposite sites, fan at entrance, restriction of movement of workers and visitors will help in prevention of carrying pathogens, Sanitary practices like restriction of smoking, eating in polyhouse, should be practiced and Practicing JPM is a systematic approach to manage pests which combines a variety of strategies to either reduce pest population or reduce their economic impact while keeping in view the international consumption and commercial standards.

ENHANCING THE YIELD AND YIELD ATTRIBUTES OF CHICKPEA BY USING NITROGENOUS FERTILIZER AND RHIZOBIUM CULTURE

PUYAMBINITADEVI^{*} AJEET PRAKASH, DIPTANU BANIK, AND MAYUR DARVHANKAR

School of Agriculture, Lovely Professional University, Phagwara, Punjab - 144411

A field experiment was conducted on chickpea to study the effect of seed treatment with rhizobium and the different level of nitrogenous doses 25%, 50%, 75% and 100% of Recommended Dose of Fertilizer (RBD) for estimating the yield and the yield attributes. The experiment was laid out in Randomized Block Design (RBD) with three replications during *Rabi* season of 2017-2018 in the experimental field of Lovely Professional University, Phagwara, Punjab, India. The aim of experiment was to focus on the variations in yield due to rhizobium treatment and different level of nitrogenous doses. The collaboration of rhizobium culture showed variations in different treatments of chickpea. The best treatment was T₅: 100% RDF in chickpea brought out fundamentally a proper growth, development and yield of the crop during this experiment.

Key words: Crop, Inorganic fertilizer, Rhizobium

HETEROSIS STUDIES IN OKRA (*ABELMOSCHUS ESCULENTS* (L.) MOENCH) FOR YIELD AND YIELD CONTRIBUTING TRAITS

QUADRI S.A., L.N. JAWALE, SYEDA J.* AND D.B. DEOSARKAR

Department of Agricultural Botany, College of Agriculture, Vasantrao Naik Marathwada Krishi Vidyapeeth, Parbhani 431 402, Maharashtra.

Analysis of variance revealed highly significant differences among genotype and parent and hybrids for all the characters studied indicating substantial amount of genetic variability present in the material. The magnitude of heterosis varied from cross to cross for all characters. Mean squares due to parents vs hybrids were significant for all the traits except fruit breadth and number of fruit/plant indicating that considerable heterosis for those characters. The highest significant Mid Parent heterosis was observed yield/plant Arka anamika × BO-13 (40.44%). The other characters showed considerable amount heterosis were number of fruit/plant for the cross Hissar Naveen × SB-8 (80.77%). The cross Parbhani kranti × BO-2 showed highest heterosis 101.88 and 16.02 for the trait yield q/ha and 1000 seed weight, respectively. The character no. of seed/fruit showed highest heterosis for the cross parbhani kranti × 136 thin (36.41) and length of fruit parbhani kranti × kashi pragati (18.27). The significant mid parent heterosis was observed for internodes (-49.60%) for the cross Hissar Naveen × Kashi pragati. The present investigation revealed that Arka anamika × BO-13, Hissar Naveen × Kashi pragati, Hissar Naveen × SB-8, Parbhani kranti × BO-2, Parbhani kranti × 136 thin and Parbhani kranti × Kashi pragati were found to be the best

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

cross combination for fruit yield and yield contributing traits which could be further exploited in future breeding programme.

Key words: Heterosis, Heterobeltiosis, Line x Tester and Okra.

EFFECT OF DIFFERENT GROWTH CONTROLLING STRATEGIES ON TREE GROWTH AND FLOWERING IN CHINESE SAND PEAR

R H S RAJA, M S WANI, Z ABHAT, A R MALIK, RAFIYAZARGAR, KOUSARJAVAI AND H UREHMAN

Division of Fruit Science, FOH, SKUAST-Kashmit, Shalimar Campus, Srinagar (J & K)

Pear is one of the most important temperate fruits next only in importance after apple. In the state of J & K, both types of pear viz., *Pyrus communis* and *Pyrus pyrifolia* exist. Nakh Kashmiri is the most important cultivar of *Pyrus pyrifolia* group considering its yield potential as well as its consumer acceptability. But due to excessive vigour there is problem of reduced flower bud development, light penetration and increased incidence of insect pests and diseases. In order to stimulate flower bud formation in pear, it is imperative to control vigour of plants. Root pruning, trunk incision and pruning are considered the major growth controlling strategies which were tested in the present study. In addition, application of growth regulators (paclobutrazol and ethephon) were tested for their efficiency in controlling tree vigour and flower induction. The study was conducted on twenty-year-old Chinese Sandy pear trees in experimental orchard/ laboratory of Division of Fruit Science, Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar, Srinagar (J&K) during the year 2011 and 2012. Trees of similar vigour and size were selected, marked and maintained under uniform cultural operations. The experimented trees were treated with root pruning (during dormancy upto 35 cm depth and 30 cm away from trunk), trunk incision (during dormancy upto 20% of trunk diameter on both sides at 30 cm distance), summer pruning (mid June- thinning out of most of the extension shoots from middle of canopy and 50% from upper and lower canopy), application of paclobutrazol (at full bloom-800 ppm and 15 days after full bloom-500ppm) and Ethephon (at full bloom-200 ppm and 15 days after full bloom-100 ppm). Plants treated with root pruning + paclobutrazol showed better results with minimum trunk growth, TCSA, internodal length maximum chlorophyll content, carbohydrate and C: N ratio (shoots and leaves), flower intensity, per cent bloom. The overall results showed that root pruning + paclobutrazol can be considered as best strategy for optimizing tree growth and flowering in pear orchard.

INTERCROPPING OF SESAME (SESAMUM INDICUM L.) WITH MUNGBEAN [VIGNA RADIATA (L.) WILCZEK] UNDER DIFFERENT LEVELS OF SULPHUR

R.K. DOUTANIYA¹, DR. Y.K. GHILOTIA², C. K. DOTANIYA³, SANDEEP MOHBE⁴

¹Department of Agronomy, O.P.J.S. University Churu Rajasthan, ² Department of Agronomy, O.P.J.S. University Churu Rajasthan,

³Division of Soil Chemistry and Fertility, ICAR-Indian Institute of Soil Science Bhopal, ⁴Division of E.S.S., ICAR-Indian Institute of Soil Science Bhopal M.P. 4620380

The field experiment comprising twenty treatment combinations replicated three times, was conducted in Randomized Block Design (RBD) with five levels of intercropping systems [sole mungbean, sole sesame, mungbean + sesame (2:1), mungbean + sesame (3:1) and mungbean + sesame (4:1)] and four levels of sulphur (0, 15, 30 and 45 kg S/ha) during kharif season, 2017 at Agronomy farm school of Agriculture, O.P.J.S. University Churu, (Rajasthan). Result showed that significantly maximum plant height of mungbean was recorded in mungbean + sesame (2:1) intercropping system, whereas sole mungbean recorded significantly more dry matter accumulation of mungbean at 40 DAS and at harvest. Mungbean + sesame (2:1) recorded significantly higher dry matter accumulation of sesame at 60 DAS and at harvest. Further, results indicated that sole mungbean, remaining at par with 4:1 and 3:1 row ratios, recorded significantly higher number of pods per plant and number of seeds per pod. Whereas sesame grown in 2:1, being at par with 3:1 and 4:1 row ratios, recorded significantly higher values of yield attributes viz., number of capsules per plant and number of seeds per capsule as compared to sole sesame. Both the sole crops (mungbean and sesame) gave significantly higher seed yield (1207 and 724 kg/ha, respectively) as compared to all other intercropping systems. The sole mungbean, being at par to 4:1 row ratio, recorded significantly higher MEY (1207 kg/ha), while mungbean + sesame (4:1) gave significantly highest LER (1.07) as compared to all other intercropping systems.

Keywords Sulphur, Intercropping, Sesame-Mungbean

EFFECT OF POTASSIUM FIXATION WITH CHLORIDE AND SULPHATE ANIONS IN SOIL ON WETTING AND DRYING CONDITIONS IN HARYANA

R.S. KALIRAMANA, B.S. PANNU AND SANTHOSH MANCHALA

Department of Soil Science, CCS, Haryana Agricultural University, Hisar-125004, Haryana. (India)

To study the effect of Potassium fixation with Chloride and Sulphate anions were wetting and drying cycles in soils of Haryana. Twelve soils were selected from different part of the Haryana for the investigation, soil samples derived from different parent material differing in their physico-chemical properties and collected at a fix depth of 0-25, 26-50, 51-75, 76-100 cms from all the soil samples. Results revealed that the most of the soils were light in texture and alkaline in reaction. The amount of Potassium fixed increased with the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

increasing days of wetting and drying cycles at different levels of Potassium from 20 to 1000 µg/ml in soil up to a depth of 25 cm. The highest amount of fixed Potassium was observed after 7 days then followed by 14 days and 28 days of drying cycles as compared to the wetting conditions. Its indicated that a period of 7 to 28 days of wetting and drying cycles sufficient for transfer of Potassium ions from the non-exchangeable Potassium pool to the available Potassium pool. Among all locations the maximum amount of Potassium fixed was observed in the Palwal soils and minimum in Chautala soils with different levels of Potassium.

Key words: Potassium fixation, wetting and drying cycles, chloride, sulphate, anions.

OPTIMIZATION OF *IN-PLANTA* METHOD OF GENETIC TRANSFORMATION IN PIGEON PEA (*CAJANUS CAJAN* L. MILLSP.)

R. A PARRAY, R. L CHAVAN*

Vilasrao Deshmukh College of Agricultural Biotechnology, Vasantrao Naik Marathwada Krish Vidyapeeth, Parbhani, Maharashtra

Pigeon pea (*Cajanus cajan* L. Millsp.) is one of the major grain legume crops of the tropics and subtropics grown in about 50 countries of Asia, Eastern and Southern Africa and the Caribbean for various uses such as food, fodder & firewood. Present study was conducted to develop and optimize tissue culture independent in planta transformation system in pigeonpea. This system can help in widening genetic base as well as solutions over various biotic and abiotic factors through engineering novel genes across the species. The various transformation parameters viz., Optical density of Agrobacterium suspension, virulence inducer and infection time were optimized through 18 different treatment combinations. The plumular and intercotyledonary meristem axes of 2-3 days old seedlings of pigeon pea cv. BSMR 853 was exploited for Agroinfection by sewing needles. Out of 270 inoculated seedlings 11.34 mean number of plantlets were recovered. The putative transformants were confirmed by GUS histochemical and PCR assay. Transformation efficiency was calculated on mean number of recovered plantlets and mean number of transformed plantlets. Among 18 different treatment combinations, the treatment pertaining Agrobacterium suspension of O.D 1.0, virulence inducer (acetosyringone) at 250 µM/ml and infection time of 1.0 min was found optimum. Among all transformation parameters, bacterial growth of O.D. 1.0 and acetosyringone concentration, 250 µM/ml has shown significant impact on transformation efficiency. The treatment comprising bacterial O.D. 1.0 with 250 µM/ml acetosyringone and 1.0 infection time 1.0 min revealed 90.02% transformation efficiency. However, lowest transformation frequency i.e. 68.76% was reported in treatment of bacterial O.D. 1.5 with 150 µM/ml acetosyringone and 0.5 min. infection time. Our investigation revealed the optimization of *in planta* transformation parameters in pigeon pea and suitability of genotype BSMR853 for genetic transformation and further genetic improvement.

Keywords - Agrobacterium, GUS gene, in planta, Pigeon pea

EFFECT OF FEEDING CROP RESIDUES BASED COMPLETE FEED RATION ON NUTRIENT UTILIZATION AND GROWTH PERFORMANCE OF KONKAN KANYAL GOATS

R. D. DAFALAPURE, N. N. PRASADE*, SHALU KUMAR, B. G. DESAI, A. J. MAYEKAR AND P. M. BOTAL

Department of Animal Husbandry and Dairy Science, Dr. B. S. Konkan Krishi Vidyapeeth (Agricultural University) Dapoli 415712, Dist. Ratnagiri, Maharashtra, India

An experiment was conducted at Dr. B. S. Konkan Krishi Vidyapeeth Dapoli, Maharashtra to assess the effect of feeding crop residue based complete ration on nutrient utilization and growth performance of Konkan Kanyal goats. In this experiment sixteen healthy Konkan Kanyal bucks of same age and average body weight were selected randomly divided into four *iso-nitrogenous* complete rations viz., T₀ (conventional feed + concentrate mixture), T₁ (60% Maize stover + 40% conc. Mix), T₂ (60% Nagali straw + 40% conc. mix.) and T₃ (60% Proso-millet straw + 40% conc. Mix) with randomized block design in each treatment there were four goats. The chemical analysis of experimental feeds T₀, T₁, T₂ and T₃ revealed that, it contains DM- 49.25, 88.63, 87.17 and 87.40, CP-13.32, 13.72, 13.61 and 13.67, EE- 3.34, 3.24, 3.49 and 3.55, Ash-11.61, 7.32, 9.70 and 12.46, NFE- 50.47, 47.71, 48.48 and 45.30, NDF- 50.31, 57.99, 45.64 and 48.22, ADF- 28.95, 37.22, 35.29 and 29.53, Ca - 1.28, 1.84, 1.42 and 1.30 and P-0.70, 0.84, 0.58 and 0.45 per cent, respectively on DM basis. The average body weight gain significantly higher in T₁ (62.5 g/day) than T₃ (55.36 g/day), T₂ (53.57 g/day) and T₀ (50 g/day). From the results of the present investigation it may be concluded that the T₁ group (60% Maize stover + 40% conc. Mix) complete feed based on maize stover crop residue found suitable for feeding and body weight gain than other crop residues for goats.

Keywords: Body weight gain, complete ration, goats and on nutrient utilization.

SUITABILITY OF *ALOE BARBADENSIS* GENOTYPES FOR SOUTH EAST REGION OF RAJASTHAN

R. K. NAGAR¹, S. B. S. PANDEY², R. R. MEENA³ AND M. SINGH

¹KVK, Kota, ²CH&F, Jhalrapatan, ³KVK, Kota, and ⁴KVK, Kota

A field experiment was conducted during kharif season of 2016-2017 on the suitability of *Aloe barbadensis* Genotypes for South East Region of Rajasthan. The experiment was conducted at the Herbal garden, Department of Forest Products and Utilization, College of

Horticulture and Forestry, Jhalrapatan city, Jhalawar. The sobriquet of *Aloe* is "Gwarpatta". The *Aloe* name is derived from the Arabic word *Aloe* mean "shining bitter substances". *Aloe* is a stem less, perennial, drought resisting, succulent plant, bearing rosettes of leaves at the end of juicy green branches and has reportedly been used since ancient times for medicinal purposes. (Rathod *et al.*, 2014). The experiment consisted of 15 genotypes, the laid out in randomized block design. The analysis variance showed highly significant variations among the genotypes for all the traits under study, which revealed the existence of good deal of variability in the germplasm the maximum plant height was recorded in [T₈, IC-112533 (57.71 cm)] and while significantly maximum number of Leaves per plant was recorded in [T₁, IC-111267 (13.44)]. Significantly maximum leaf length was recorded in [T₈, IC-112533 (54.55 cm)]. and maximum leaf width was recorded in [T₈, IC-112533 (8.14cm)]. The maximum leaf Thickness recorded was in [T₉, IC-112534 (12.74 mm)] and maximum leaf yield (Fresh) per hectare was recorded in the genotypes [T₉, IC-112534 (48.85 t.)]

Key words: - *Aloe barbadensis*, genotypes, experiment, growth, yield, quality

EFFECT OF PRE HARVEST APPLICATION OF BIOFORMULATIONS ON LATENT INFECTION OF MANGO ANTHRACNOSE

R. UDHAYAKUMAR

Department of Plant Pathology, Faculty of Agriculture, Annamalai University, Annamalai Nagar 608002 (T.N), India.

The Effect of pre harvest application of bioformulations individual and combination spray on latent infection of mango anthracnose was studied. Both individual and combination application of bioformulations (*P. fluorescens* (BIB₂) + *B. subtilis* (BIL₈) + chitin) significantly reduced the disease incidence when compared to control. Pre harvest application of *P. fluorescens* (BIB₂) + *B. subtilis* (BIL₈) + chitin on 20 days before flowering, flowering stage, 20 and 60 days after flowering plus Carbendazim (0.1%) at 40 days after flowering recorded the minimum disease incidence (8.33 per cent) at 14 days after storage and was on par with T₈ - Carbendazim (0.1%) on 20 days before flowering, flowering stage, 20, 40 and 60 days after flowering recorded 7.67 per cent at 14 days after storage. It was followed by application of *P. fluorescens* (BIB₂) + *B. subtilis* (BIL₈) + chitin @ 5g/litre of water on 20 days before flowering, flowering stage, 20, 40 and 60 days after flowering.

EXPLOITATION OF ESSENTIAL OILS AS AN ALTERNATIVE STRATEGY TO CONTROL STEM END ROT DISEASE OF MANGO

R. LOGESHWARI* AND DR. R. UDHAYAKUMAR

**Department of Plant Pathology, Faculty of Agriculture, Annamalai University, Chidambaram, Tamil Nadu- 608 002*

Mango, being a perishable fruit, is subjected to various post-harvest diseases caused by different pathogens. Among post-harvest diseases of mango fruit, Stem end rot disease caused by *Lasiodiplodia theobromae* is the major issue. The aim of the present study was to investigate the efficacy of five essential oils extracted from lemon grass, citronella, citriodora, geranium and turmeric leaf oil on the mycelial growth of *L. theobromae* under *in vitro* condition. The *in vitro* antifungal activity was tested by the poisoned food technique. The results showed that citriodora oil showed 100 per cent mycelial inhibition of *L. theobromae* over control @ 0.02%. This was followed by citronella oil 41.94, 58.61 and 100 per cent inhibition over control at 0.02, 0.04 and 0.06% conc. respectively. Similarly lemon grass oil and geranium oil showed 100 per cent mycelial inhibition at 0.10 and 0.12% conc. Respectively.

PRECISION AGRICULTURE, SOIL AND WATER CONSERVATION FOR SUSTAINABLE RADHAKISHAN YADAV AND GAVASKAR

Department of Soil Science and Agri. Chem., Naini Agricultural Institute, Sam Higginbottom University of Agriculture, Technology and Sciences, Allahabad, 211007 U.P., India.

The concept of precision agriculture (PA) and sustainability are inextricably linked. From the first time a global positioning system was used on agricultural equipment the potential for environment benefits has been discussed. Intuitively, applying fertilizers and pesticides only where and when they are needed, should reduce environment loading. Precision agriculture is one of many modern farming practices that make production more efficient. With precision agriculture, farmers and soils work better, not harder. Conservation of soil and water resources is important for sustainability of agriculture and environment. Soil and water resources are under immense pressure due to ever increasing population thereby ensuing growing demand for food, fiber and shelter. Soil and water resources are being deteriorated due to different anthropogenic and natural factors. Soil erosion is one of the several major deteriorative processes which results in deterioration of the soil. Soil erosion is removal of soil due to movement of water and/or air. Soil erosion may lead to the significant loss of soil productivity and thus may lead to the desertification under severe conditions. Water and wind are the major agencies which are responsible of soil erosion. Deforestation, over-grazing, mismanagement of cultivated soils, intensive cultivation and intensive urbanization are major factors triggering the soil erosion. For sustainable agriculture and environment, it is pertinent for

the protection of soil resources against erosion. Different control measures should be adopted to protect the soil resources against erosion. The concept of soil conservation cannot be materialized without conserving and efficient use of water resources. It is therefore pre-requisite that soil conservation practices should be adopted. Soil conservation practice include soil management, crop management, engineering, range management and operation.

Keywords: Soil, Water, Erosion, Conservation, Sustainable etc.

VARIATION IN PHYSICAL AND PHYSICO-CHEMICAL PROPERTIES OF DIFFERENT CULTIVARS OF JACKFRUIT SEEDS HARVESTED FROM NORTHERN REGION OF INDIA

RADHA KUSHWAHA AND DEVINDER KAUR

Centre of Food Technology, University of Allahabad, 211002

The jackfruit is the largest tree-borne fruit belongs to family *Moraceae*, composed of pulp, seed and rind. Seed contains 10 to 20% weight of the total fruit. In the present study the physical and nutritional properties of jackfruit seeds were analyzed. Five different cultivars were used in study viz. Hadiyava, Bhadaiyan, Khaja, Safeda, and Katahri. The average moisture content of seeds was 48.62 to 67.84% (wet basis). The average for the three characteristic dimensions, length, width and thickness was 2.30 to 2.77 cm, 1.45 to 1.93 cm and 1.22 to 1.64 cm among the seeds from different cultivars, respectively. The geometric mean diameter was 1.72 to 2.04 cm for all the cultivars. The bulk density of seeds ranges from 0.44 to 0.53 g cm⁻³. Jackfruit seed contains 13.30 to 16.60% of protein content. Safeda cultivar has the highest protein content (16.60%) than other cultivars. The seeds have a sufficient amount of carbohydrates. Seeds of jackfruit can be used as the production of flour and starch.

Keywords: Jackfruit, dimensions, geometric mean, Bulk density, Seed.

STUDIES ON EXOTIC APPLE VARIETIES UNDER HIGH DENSITY ORCHARDING IN NORTH HIMALAYAN REGION OF INDIA

RAFIYA MUSHTAQ, ASHAQPANDIT, AMIT KUMAR, M K SHARMA, R H S RAJA AND J PRATHORE

Division of Fruit Science, FOH, SKUAST-Kashmit, Shalimar Campus, Srinagar (J & K)

The present study entitled studies on Exotic Apple Varieties under High Density Orchardling in North Himalayan region of India was undertaken at experimental fields of Division of Fruit Science, SKUAST-Kashmir, during the year 2014. In order to solve the problems of low productivity, poor quality, less color and irregular bearing habits in current apple plantations in India, and compete with the productivity of advanced countries, four apple varieties namely Super Chief Sandidge, Gala Red Lum, Fuji Zhen Aztec and Golden Clone B were imported from Italy on M9T337 rootstock and planted at a distance of 1.5 × 3m on four wire trellis system (2222 trees/ha). Tree morphology, growth characteristics, phenological stages, flowering behavior, floral/fruit characteristics, physical, chemical and organoleptic measurements were performed on all the four varieties. The variety Super Chief Sandidge performed best in terms of quality parameters, variety Golden Clone B recorded highest yield (10 Mt/ha) and yield efficiency. The overall results indicate that the introduced apple varieties are characterized with different biological and quality polymorphism. All of the studied varieties show positive characteristics and can be recommended for further evaluation in Kashmir valley.

CONSERVATION TILLAGE FOR SUSTAINABLE AGRICULTURE PRODUCTION AND ECO-SAFETY

RAGHAVENDRA NAGAR*

Department of Agronomy, College of Agriculture, Junagadh Agricultural University, Junagadh, Gujarat

Traditional agriculture, based on tillage and being highly mechanized, has been accused of being responsible for soil erosion problems, surface and underground water pollution, and more water consumption, while conservation agriculture is a management system that maintains a soil cover through surface retention of crop residues with no till/zero and reduced tillage. CA is described by FAO as a concept for resource saving agricultural crop production which is based on enhancing the natural and biological processes above and below the ground. The main components of conservation tillage are zero tillage, minimum or reduced tillage, strip tillage, no-tillage, raised bed system, crop diversification and crop residue managements. The main advantage of CT are the reduced erosion and increase organic matter and ultimately increase the yield and maintain soil health. Till planting is the method of zero tillage. Crop residue can be used as mulch to cover the soil to reduce erosion, maintain soil moisture, improve soil tilth and quality, reduce nutrient runoff, and provide wildlife cover instead of burning them on field. Laser land leveling and directed seeding of rice are the resources conserving techniques.

Key word: Traditional agriculture, water pollution, crop diversification, wildlife, Laser land leveling.

A POSITIVE APPROACH TO HELP AGRICULTURAL SYSTEM THROUGH SUSTAINABLE INTENSIFICATION AND CLIMATE-SMART AGRICULTURE**RAGINI KUMARI AND SUNIL KUMAR***Asstt. Professor-cum-Jr.Scientist, Department of Soil Science & Agricultural Chemistry, Bihar Agricultural University, Sabour (Bhagalpur)-813210*

Climate is the primary important factor for agricultural production. Concerning the potential effects of climatic change on agriculture has motivated important change of research during the last decade. Agriculture is a foundation of the climate change equation. While it is seriously affected by global warming, agriculture is also a major source of greenhouse gases which contribute to the problem in the first place. However ending hunger, food insecurity and malnutrition for all will require continued and focused efforts to increase capacity for agricultural productivity. Climate-smart agriculture (CSA) and sustainable intensification (SI) are a positive approach to help agricultural systems worldwide, concurrently addressing three challenge areas: increased adaptation to climate change, mitigation of climate change, and ensuring global food security-through innovative policies, practices, and financing. The 'sustainable intensification' (SI) approach and 'climate-smart agriculture' (CSA) are highly complementary. SI is an essential means of adapting to climate change, also resulting in lower emissions per unit of output. With its emphasis on improving risk management, information flows and local institutions to support adaptive capacity, CSA provides the foundations for incentivizing and enabling intensification. SI and CSA are crucial for global food and nutritional security, they are only part of a multi-pronged approach that includes reducing consumption and waste, building social safety nets, facilitating trade, and enhancing diets.

CHARACTERIZATION OF UPLAND AHU RICE ACCESSIONS USING SSR MARKERS ASSOCIATED WITH DROUGHT TOLERANCE**RAHUL C KALDATE¹, MAYURI D MAHALLE¹, RAHUL K VERMA¹, SANJAY K CHETIA², PRADIP C DEY², A. ROY³, MAHENDRA K MODI¹***¹Department of agricultural biotechnology, AAU, Jorhat-785013, ²Reginal Rice Research Institute, AAU, Titabar-785632, ³Regional Agricultural Research Station, AAU, Diphu-782462*

We have studied 5 rice accessions using 24 drought linked SSR markers to identify drought responsive QTLs along with a respective resistant check. The screening result obtained for *qDTY1.1*, *qDTY2.3*, *qDTY3.1*, *qDTY4.1*, *qDTY6.2*, *qDTY10.1*, *qDTY12.1* from their related markers shows promising result for the accessions under study. Genetic diversity analysis was carried out using 21 polymorphic markers. The number of alleles per locus ranged from 2 to 5 with an average of 2.95. The polymorphic SSRs revealed high diversity measures such as mean values of expected heterozygosity (H_e ; 0.61), observed heterozygosity (H_o ; 0.20), the polymorphic information content value (0.91) was obtained for RM12091 and RM12141 followed by RM13600 (0.75) with an average of 0.54. The PIC values revealed that RM12091 and RM12141 were considered as the best markers for the identification of rice genotypes under study. Cluster analysis based on 21 simple sequence repeat markers revealed 3 branches and indicated the presence of variability within the selected rice germplasm. The screening of drought related QTLs along with genetic diversity estimates can be important for devising future breeding programmes in rice.

Key words: Upland rice accessions; genetic diversity; drought tolerant QTLs; simple sequence repeat marker, principal component analysis.

EFFECT OF DIFFERENT PRUNING INTENSITIES IN *DALBERGIA SISSOO* ON GROWTH AND YIELD OF PADDY AND MUSTARD+ GRAM+ WHEAT VARIETIES UNDER AGRISILVICULTURE SYSTEM.**RAHUL DONGRE, M. L. SAHU, POORNIMA MALVIYA, B. D. GHODE AND S. D. UPADHYAYA***Department of Forestry, College of Agriculture, JNKVV, Jabalpur, MP, India*

Experiment was conducted during 2016 to evaluate the "Effect of different pruning intensities in *Dalbergia sissoo* (5x5m) on growth and yield of Paddy and Mustard+ Gram+ Wheat varieties under Agrisilviculture system." at JNKVV, Jabalpur, M.P, India Under 18 years old agrisilviculture system (D.sissoo + Paddy-Mustard/Gram/Wheat rotation) where 4 pruning treatments (viz; no pruning, 25%, 50% and 75% pruning) and one open were carried out in main plot and three crop rotation i.e. [T1- Early paddy (Danteshwari) + Mustard], [T2- Medium paddy (MTU-1010) + Gram], [T3- Late paddy (Kranti) + Wheat] in sub plot; replicated five times. Different pruning treatments showed significant influence on grain yield of paddy varieties. Significant maximum grain yield of paddy was recorded under open condition (1600 kg ha⁻¹) at par with 75 % pruning (1464 kg ha⁻¹) and 50 % pruning (1333 kg ha⁻¹). No pruning recorded significantly lowest grain yield (862 kg ha⁻¹) at par with 25 % pruning (875 kg ha⁻¹). The percent reduction in grain yield under no pruning, 25%, 50% and 75% pruning as compared to open condition was 46%, 45%, 16.7% and 8.5%, respectively. During Rabi season crops viz., mustard, gram and wheat were sown after paddy. Significantly higher wheat equivalent yield (8832 kg ha⁻¹) was recorded under open condition and was significantly superior to all the pruning treatments. No pruning recorded significantly lowest yield (5063 kg ha⁻¹). Significantly

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

higher wheat equivalent yield (15766 kg ha^{-1}) was recorded under late paddy + wheat followed by early paddy + mustard (2787 kg ha^{-1}) and medium paddy + Gram (1176 kg ha^{-1}) which were at par. Significantly maximum net monetary return was recorded under *D. sissoo* + medium paddy (MTU-1010) + Gram (Rs. 63688 ha^{-1}) crop rotation closely followed by *D. sissoo* + early paddy (Danteshwari) + Mustard (Rs. 63138 ha^{-1}).

Keyword- Pruning, D.Sissoo, economic return, Agrisiviculture system.

EFFECT OF ORGANIC AND INORGANIC SOURCES OF NUTRIENTS ON YIELD, QUALITY AND NUTRIENT UPTAKE BY MUSTARD (*BRASSICA JUNCIEA* L.)

RAHUL KUMAR AND SHIPRAYADAV

Department of Agronomy, SVP University of Agriculture & Technology, Meerut (UP) India-250110

In India, it is the third most important edible oilseed crop after soybean and groundnut sharing 27.8% in the India's oilseed economy. The global production of mustard and its oil is around 38-42 mt & 12-14 mt respectively. India contributes 28.3% and 19.8% in world acreage and production. India produces around 6.9 mt of rapeseed-mustard next to China (11-12 mt) and EU (10-13 mt) with significant contribution in the world mustard industry. Plant height Total Dry matter accumulation, leaf area index and seed and stover significantly higher when RDF 120:17.6:16.6:40 N:P:K:S kg/ha was applied along with FYM 10 t/ha. Higher values of growth parameter viz. number of branches, plant height, yield attributes, seed and stover yields were recorded in plots receiving 75% RDF + 5 t/ha FYM + Zn 10 kg/ha + S 25 kg/ha respectively. Plant height, dry matter accumulation, primary and secondary branches per plant, chlorophyll content in fresh leaves, seed/siliqua, 1000-seed weight and seed and stover yields were significantly higher under incorporation of FYM 20 t/ha over 10 t/ha. It is revealed that use of organic and inorganic sources of nutrients out beneficial all ways besides improving the growth, yield and quality of mustard.

Keyword: Mustard, Organic, inorganic sources.

INTEGRATED PEST MANAGEMENT IN RICE THROW BOTANICALS

RAHUL KUMAR, VINOD KUMAR, MAHENDRA PRATAP GAUTAM

Department of Agronomy, SVP UA & T, Meerut, UP, India.¹, Department of Entomology, SVP UA & T, Meerut, UP, India.

Rice is one of the oldest domesticated crops and due to its importance as a food crop humans took it with them when settling in new areas further removed from flooded river plains extending to the uplands. For thousands of years, rice, with the exception of some dryland systems, was grown in monoculture. The greater incidence of insect pest leads to greater chemical application resulting in higher input cost and agro- ecological imbalance. It is an established fact that SRI has low insect pest and disease incidence resulting in low or nil chemical pesticide application. The farmers are advised to practice the non-chemical managements unless and until the damage does not crossed the threshold limit. Apart from the pest wise management options, few ITKs that have been proved beneficial against certain insect pests. Different control and management practices are utilised in IPM with the objective of achieving long term results - Such as (i) Identification of threshold pest level at which action needs to be taken (ii) Monitoring and identification of pests (iii) Prevention the use of management practices to reduce the likelihood of pests (iv) Control once the pest has been correctly identified, monitoring has shown it has reached a threshold level, and preventative measures are no longer appropriate, control measures will be used.

Keywords: Integrated pest management, Rice

EVALUATION OF DIFFERENT GENOTYPES OF GAILLARDIA (*GAILLARDIA PULCHELLA* FOUG.) UNDER JHALAWAR CONDITION

RAHUL KUMAR BYADWAL¹, PARVEEN CHOYAL², APOORVA PALLED³ AND MANISH KUMAR MEENA⁴

^{1,2} Ph.D Scholar, SKN College of Agriculture, Jobner, Jaipur, ^{3,4} College of Horticulture & Forestry, Jhalawar (AU, Kota) Rajasthan

An experiment was carried out at the Instructional Farm, Department of Floriculture and Landscaping, College of Horticulture & Forestry, Jhalrapatan, Jhalawar, (Agriculture University, Kota) during the period from March, 2017 to September, 2017 to study the performance of the twelve genotypes of gaillardia. The maximum plant height (81.03 cm) and leaf width (4.38 cm) were recorded in the genotype 'Genotype-3'. The genotype 'Genotype-2' produced the maximum number of primary branches per plant (18.87) fresh weight (1626.93 g) and dry weight (321.46 g) of plant was recorded in 'Genotype-2' respectively. The highest plant spread (73.70 cm) was recorded in the genotype 'Genotype-6'. The maximum leaf length (11.67 cm) was recorded in 'Genotype-7'. The maximum flower diameter (6.29 cm), days taken to first flower opening (42.60 days), days taken to 50 per cent flowering (64.93 days), number of flowers per plant (131.35), weight of flowers per plant (578.72 g), weight of flower per plot (45.89 kg), the highest flower yield per hectare (395.26 q/ha) were recorded in 'Genotype-11'.

Keywords: Gaillardia, Genotype, Dry weight, Spread and Pluckings

TITLE :SOIL HEALTH, NUTRIENT RECOVERY AND PERFORMANCE OF TRANSPLANTED RICE AS INFLUENCED BY EFFICIENT NITROGEN MANAGEMENT**RAHUL KUMAR VERMA (MSc. SOIL SCIENCE)***Department of Soil Science and agricultural chemistry, Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut (U.P) 250110*

Rice (*Oryza sativa* L.) is one of the most important cereal crop of the India, grown in wide range of climatic zones, to nourish the mankind, but maximizing the yields requires the input of supplemental nutrients and better soil health. The soil health refers to self-regulation, stability, resilience, and lack of stress symptoms in a soil as an ecosystem. Soil health describes the biological integrity of the soil community the balance among organisms within a soil and between soil organisms and their environment, (Acharaya *et al.*, 2008). Soil quality is a term that more often is used to describe physical, chemical and biological attributes of a soil. Efficiency of fertilizer nitrogen is quite low, especially in the tropical regions, where rice is the principal crop (Prasad, 2013). Nitrogen use efficiency can be improved by checking the path ways of losses from soil-plant system, making integrated system of nutrients from all possible sources, optimal allocation of nutrients to crops and maximizing the utilization of applied and native nutrients by the crops (Duttarajan *et al.*, 2014). Rice production and nitrogen recovery is enhanced through soil health management can be achieved by adopting integrated nutrient management, site specific nutrient management, slow-release nitrogenous fertilizers (SRNF) and also conservation agriculture practices. Research reports of long term studies reveal that organic manures in addition to fertilizers sustain high crop yields over long periods compared to application of only fertilizers. (Barik *et al.* 2006). It is concluded that rice production through soil health management in India can be achieved through a proper understanding of the nutrients needs and meeting them through LCC, SPAD and SSNM and use of conservation agriculture technologies. It also enhance fertilizer use efficiency as well as lower the losses of nutrient particularly nitrogen in rice crop.

ECO-FRIENDLY MANAGEMENT OF SHOOT AND FRUIT BORER (*LEUCINODES ORBONALIS* GUENEE) OF EGG PLANT BY THE APPLICATION OF ORGANIC MANURES AND BIO-PESTICIDES***RAHUL KUMAR AND FAZAL AHMAD***Department of Entomology, Chandra Shekhar Azad University Of Agriculture And Technology Kanpur 208002, Uttar Pradesh, India*

Aubergine is an important dietary vegetable grown all over the country. The crop is subjected to high degree of instability in production, mainly on account of losses caused by different insect pests at different stages of the crop. The mean data of 2007 and 2008 showed that the minimum shoot borer infestation 21.4 % was recorded in the treatment NSKE 5%. The fruit borer infestation showed the minimum borer infestation of 18.9 % in the treatment NSKE 5%. Nearly 25.82 to 92.50% damage is attributed due to shoot and fruit borer. Among the treatments Chlorpyrifos 20 EC found superior over all the treatments followed by Chlorpyrifos + Neem oil and Chlorpyrifos + NSKE after first, second and third sprays respectively. eco-friendly management of brinjal shoot and fruit borer, *L. orbonalis* through organic manures revealed that maximum (75%) requirement of the nitrogen by the crop provided through the neem cake combined with the inorganic fertilizers. While, FYM recorded the maximum population of natural enemies. Also, maximum yield of healthy brinjal fruits was recorded in the treatment where 75 per cent of the recommended dose of nitrogen was provided through neem cake. More studies on bio-efficacy of bio-pesticides against brinjal shoot and fruit borer, *L. orbonalis* revealed that profenophos (40%) + cypermethrin (4%) 0.04 per cent, NSKE 5 per cent and neemazal 0.005 per cent were found most effective against the pest with minimum shoot and fruit infestation.

PROTECTED CULTIVATION: IMPORTANT STRATEGIES IN HI-TECH HORTICULTURE**RAJ BALA CHOUDHARY¹ AND PRIYA NEGI²***Department of Horticulture, Sri Karan Narendra Agriculture University, Jobner, Jaipur (Raj.) 303329*

Hi-tech horticulture is technology intensive production system. It is time and space dimensions compatible system of production in which inputs and resources are combined judiciously so as to maximize return many times more than the conventional system. Actually, constrained by rhythmic change in climate to grow the crop whenever needed. In protected cultivation, attempt is made to avert incompatibility of climate using artificial means and its benefits is harnessed in terms of harvesting produce out of their normal growing season. Demand of a particular produce all over the year round has provided due back up to the protected cultivation. With boom in retail sector, protected cultivation is catching fast momentum in India. High value, low volume crops are preferential for green house cultivation. A variety of crops like strawberry, capsicum, tomato, cucumber, rose, gerbera, chrysanthemum, cactus, anthurium, orchids etc. are under cultivation in green house. Green house, low tunnels, plastic tunnels, lath house, cold frame, shade net house etc. are the some growing structure and it enables crops could be grown under inclement climatic conditions, efficient utilization of precious inputs like water and nutrients, early nursery and early cropping, superior quality of the produce, effective control against pests-diseases,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

reduced expenditure on weed control and protection against heavy rains, hails, birds etc. Hence, the productivity and quality enhancement of any produce largely depends on level of protection and congenial conditions available to plants. However, the technology being worth increasing yield by as high as 300 per cent, it needs due adoption.

Keywords: Climate, Crops, Growing Structure, Hi-Tech Horticulture.

IMPROVE PRODUCTIVITY USING HIGH DENSITY PLANTING IN FRUIT CROPS

RAJ KIRAN

Msc. Ag. (Horticulture), GBPUAT, Pantnagar

India is the largest producer of fruits in the world. Now-a-days population of India is continuously increases so require more production per capita. Fruits are rich source of minerals and vitamins. Which is necessary to develop a healthy and good nation but the average productivity of fruits in India is low as compared to many developed countries. The main reasons for the low productivity are old and senile orchards, low yielding varieties, poor orchard management and inadequate technological up-gradation and adoption by the growers. Presently, the continuously decline in the availability of cultivable land, rising energy and land costs together with the mounting demand of horticultural produce, have given thrust to the concept of high density planting (HDP) of horticultural crop. High Density Planting (HDP) is a very intensive form of fruit production which has high relevance to the food and nutritional security of our ever increasing population. Some factors are affecting HDP such as:

1. Methods of HDP., 2. Use genetically dwarf scion cultivars and rootstock, 3. Training and pruning, 4. Use of growth regulators, 5. Use of growth retardant.

KEYWORD: Horticulture orchard management, production, senile orchard, HDP, genetically dwarf scion and rootstock cultivar and PGR.

CROPIMPROVEMENT BY CONVENTIONAL BREEDING OR GENETIC ENGINEERING

RAJ SINGH CHOUDHARY^{1*}, OM PRAKASH YADAV¹, NARESH KUMAR YADAV¹

1 Division of Soil Science and Agriculture Chemistry, Sher-e-Kashmir University of Agricultural Science and Technology, Chatha, Jammu-180009 (J&K) India

Genetic Engineering has offered tremendous scope and potential to conventional Breeding methods of crop Improvement, crop protection, crop quality management and other horticultural traits. Genetic Engineering extends tremendous opportunities in fruit production by providing new genotypes for breeding purpose, supply of healthy and disease free planting material, improvement in fruit quality, enhancing shelf-life, availability of bio-pesticides, bio-fertilizers, etc. Genetic engineering consists of isolation of a gene of interest, ligating that gene with a desirable vector to form the recombinant-DNA molecule and then transferring that gene into the plant genome to create a new function. Horticultural biotechnology has been a leading example in the following mentioned areas for more than two decades, right from the commercialization of the first ever transgenic crop in the form of Flavr-Savr transgenic tomato with enhanced shelf life trait. Currently transgenic maize, soybean, cotton, and other crops, with genetically modified pest resistance, herbicide resistance, and quality-improved crops, have been developed and grown worldwide. The RNAi technology has found its most powerful expression in plant biology these days. The applications of this technology cover a wide range from producing insect, viral and disease resistant plants to developing designer flower colors by knocking down the expression of certain endogenous genes. Biotechnological interventions that could increase the efficiency of horticultural crop improvement are essential to generate plants with several desirable traits.

Key words: Genetic engineering, Horticultural crops, Insect resistance, RNAi.

EFFECT OF NITROGEN, PHOSPHORUS AND BIO-FERTILIZERS ON GROWTH AND YIELD ATTRIBUTES OF GARDEN PEA (*PISUM SATIVUM* L.)

RAJARAM BUNKER¹, DR.R.K.NAROLIA², OMPRAKASH¹, SUNIL KUMAR YADAV¹, SURESH KUMAR MEENA¹

**M.Sc Scholar¹, Assistant professor², Department of Horticulture, College of Agriculture, S.K.R.A.U. Bikaner-334006 (Rajasthan), India*

The field experiment was conducted at Instructional Farm, College of Agriculture, Swami Keshwanand Rajasthan Agricultural University, Bikaner during *rabi* season year 2017-18. To study the Effect of Nitrogen, Phosphorus and Bio-fertilizers on Growth and Yield Attributes of Garden Pea (*Pisum sativum* L.) cv. Arkel. The experiment was laid out in RBD with 11 treatments in 3 replication on different nitrogen and phosphorus levels and in combination with bio-fertilizers compared to control. The treatment 20 Kg ha⁻¹ N + 40 kg ha⁻¹ P + *Rhizobium* + PSB (T₃) showed significant increase in the growth and yield attributes as compared to control but statistically at par with 20 Kg ha⁻¹ N + 40 kg ha⁻¹ P + *Rhizobium* (T₃) and 20 Kg ha⁻¹ N + 40 kg ha⁻¹ P + PSB (T₄) where as green pod yield (kg/plot and q/ha)

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

was found maximum at T₅ being statistically at par with T₃ and T₄.

Keyword- Nitrogen, Phosphorus, *Rhizobium*, PSB, Pea, Growth, Yield, etc.

SCENARIO OF ROOT KNOT NEMATODES AND THEIR MANAGEMENT

RAJAN KAMBOJ¹, NAVEEN RAO AND RAKESH KUMAR

Department of Entomology, CCS Haryana Agricultural University, Hisar

Root knot nematodes (*Meloidogyne* Goeldi) are sedentary endoparasites of diverse group of crops and are one of the most important polyphagous crop pests. Root knot nematodes are the members of phylum Nematoda, class Secernentea, order Tylenchida and family Heteroderidae. They are adapted to feed on large number of plants and over 3000 wild and cultivated plant species are reported to be affected. Their infestation on plant roots induce typical symptoms, popularly known as 'root knot' or 'root gall', so named as 'root knot nematodes'. Root knot nematodes are distributed worldwide from tropical to temperate regions. Over 106 species of root knot nematodes have been recognized from different parts of the world. In India, fourteen species are recorded from different regions whereas in H.P. four species namely, *Meloidogyne incognita* (Kofoed & White) Chitwood, *M. javanica* (Treub) Chitwood, *M. graminicola* Golden & Birchfield and *M. hapla* Chitwood occur. Root knot nematodes have very wide host range and are important pest in different crops such as cereal crops (rice), pulses (blackgram, cowpea, pigeonpea), oilseeds (castor, groundnut, sesamum, sunflower), vegetables (brinjal, carrot, cucurbits, okra, tomato), fruits (citrus, pomegranate, banana, apple, peach, plum), spices (black pepper, cardamom, ginger, turmeric), fiber crops (cotton, jute), plantation crops (tea), ornamental crops (carnation). It has been recorded as a menace for global production and estimated crop losses due to major plant parasitic nematodes in world is over \$157 billion. Losses in India are to the tune of Rupees 21 billion. Root knot nematode cause distinct swelling (gall) by which water and nutrient uptake capacity of the plants reduces. It also allows entries of other pathogens such as fungi and bacteria resulting in secondary disease situation. Sandy loam soil with 24-30°C temperature and optimum moisture favour the multiplication of root knot nematodes. For the management of *Meloidogyne* spp. both preventive and curative measures are practiced. Preventive measures are the cultured methods (fallowing, deep ploughing, crop rotation, soil solarization, steaming, organic amendments, growing antagonistic crops etc.), use of nematode free planting material, sanitation (removal of infested plants along with roots, weeding), host plant resistance (resistant varieties, identification and cloning of R-gene, producing transgenic plants with R-gene, transgenic proteinase inhibitor type resistance, expressing gene producing toxic substance to nematodes) and biological control (*Trichoderma* spp., *Paecilomyces lilacinus*, *Pseudomonas fluorescens*) whereas curative approaches relies on the use of safe, judicious and recommended chemical nematicide namely, Carbofuron 3G, Carbosulfon 25DS, Dazomet.

BEEKEEPING IN INDIA

RAJAT DESHWAL¹, VISVASH VAIBHAV², NITIN KUMAR³, RAHUL SINGH⁵ AND ANKIT KUMAR⁵

^{1,2,3,4}Department of Entomology & ⁵Pathology Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut 250110 U.P. India

Beekeeping plays an important role in the sustainable agriculture as it contributes significantly for diversification of agriculture. Beekeeping is an interesting hobby, an ideal agro-based subsidiary enterprise, providing supplementary and sometimes major source of income to the farmers, especially to the small farmers. It is an ideal, eco-friendly and non-land based rural enterprise, which does not tax the farm resources and provide sustainable livelihood to the rural people, including landless and women. Beekeeping production is affected by indiscriminate use of pesticides, bee diseases and enemies, adverse effects of weather, low price of products, etc. The susceptibility of honey bees to different diseases, pesticide hazards and marketing of bee products were found to be major limiting factors in the prospects of beekeeping. Majority of the beekeepers wanted to increase their level of business. Therefore, the specialized training courses should be organized to overcome these problems and promote their business. The problem of bee diseases and natural enemies is a major constraint in beekeeping industry. Sometimes, the diseases remain undetected for long and when they appear, cause catastrophic destruction. Treatment of bees for disease is a challenge even to the pathologist. The spread, intensity and control of disease are affected by climatic factors, forage availability and quality. India, one of the largest honey producer and exporter in the world, plays an important role in world honey production and trade. In India beekeeping has been mainly forest based. Bee hives neither demand additional land space nor do they compete with agriculture or animal husbandry for any input. The beekeeper needs only to spare a few hours in a week to look after his bee colonies. Beekeeping is therefore ideally suited as a part-time occupation. Beekeeping constitutes a resource of sustainable income generation to the rural and tribal farmers. It provides them valuable nutrition in the form of honey, protein rich pollen and brood. Bee products also constitute important ingredients of folk and traditional medicine. A small quantity has been used in kitchen as an ingredient of pickles, jams and preserves. Forest honey is used in pharmaceutical, food, confectionery, bakery and cosmetic industries. Royal jelly, Bee wax, Bee venom, Propolis, etc. However, there are many constraints which affect the promotion of beekeeping in India

SCREENING OF PEACH CV. SHAN-E-PUNJAB AGAINST VARIOUS PROPAGATION TECHNIQUES RAJAT SHARMA, D.C. DIMRI, ANKIT DONGARIYAL, SHWETA UNIYAL AND PUSHPENDRA RAJPUT

Department of horticulture, GBPUA&T, Pantnagar Uttarakhand

Peach is one of the most delicious temperate fruit crop of India occupying prime position in its importance. Its propagation study on different rootstocks was carried out at G.B.P.U.A&T, Pantnagar. The scion of Shan-e-Punjab variety were grafted on Peach seedling with different methods i.e., tongue grafting, chip budding and tongue grafting and time of grafting i.e., January to August under different growing conditions with Factorial Randomized Complete Block Design and three replications. These plants were budded/grafted between January to August, 2017. The results of the study showed that tongue grafting in January was found to be superior compared to all other method and timings. However, results from T-budding show lower values for days taken for 50% sprouting, success percentage, root growth parameter etc. Chip budded plants showed higher cost benefit ratio followed by tongue grafting and T-budding. Sprouting percentage, number of leaves, plant height and number of saleable plants were found to be highest in tongue grafted plants compared to the other propagation techniques. From the study, it was concluded that the peach cv. Shan-e-Punjab responded well to tongue grafting and chip budding than T-budding. Since, all the growth parameter were maximum in case of tongue grafting. Hence, tongue grafting was recommended for the commercial method of propagation for peach cv. Shan-e-Punjab.

COMBINE EFFECT OF CONTAINERS AND GENOTYPES ON UN-GERMINATED SEEDS IN STORAGE IN RICE ¹RAJBIR SINGH AND ²KARUNA VISHUNAVAT

¹Depeartment of Plant Pathology, Gochar Mahavidyalaya, Rampur Maniharan, Saharanpur-247451 (UP), India, ²Depeartment of Plant Pathology, G.B. Pant University of Agriculture and Technology, Pantnagar-263145 (Uttarakhand), India

The present study was undertaken to know the combined effect of different containers (poly bags and cotton bags) and genotypes (CMS 58025 A, CMS 58025 B, IR-66, KMR-3 and Pant Dhan 11) on per cent un-germinated seeds in rice at different storage period (January to May). It has been reported that in irrespective of both the containers, the minimum percentage of un-germinated seeds was in genotype KMR-3, while the maximum percentage of un-germinated seeds has been recorded in CMS 58025 A and CMS 58025 B at all the storage period.

EFFECT OF LENTIL VARIETIES UNDER VARIOUS METHODS OF ESTABLISHMENT IN RAINFED DROUGHT-PRONE CONDITION OF BIHAR.

RAJEEV SINGH¹, NITYANAND¹, A.K. SINGH², R. K. SOHANE³, R. N. SINGH⁴, ANJANI KUMAR SINGH⁵, SANGITA MEHTA¹, RAVIRANJAN KUMAR¹, PRAVEEN KUMAR¹ AND SUNITA KUMARI¹

¹Krishi Vigyan Kendra, Aurangabad, ²V.C., BAU, Sabor, Bhagalpur; ³DEE, BAU, Sabour; ⁴ADEE, BAU, Sabor; ⁵Director ATARI, Patna Bihar Agricultural University, Sabour, Bhagalpur

Lentil is the most important pulse crop in India that holds key to nutritional security. In Aurangabad district Lentil is a dominating pulse under rice based agricultural system. There is high potential to increase productivity of lentil by selecting suitable variety and better crop raising techniques. Lentil has higher area under paira cropping. Hence probable suitable varieties are being tested in Aurangabad area. The thrust is to have enough pulse production for ever growing need of population. These varieties would be raised following best management practices. The field experiments were carried out at the KVK, Aurangabad and farmers' field (Latitude: 24.50° N, Longitude: 84.70° E, Mean sea level height: 332ft) during rabi season 2013-14 in rainfed lowland having clay loam soil type. Performance of three varieties; HUI-57, PL-06 and PL-08 were evaluated under different method of establishment viz; line sowing with seed drill and sowing with Zero tillage with BMP cultivation practices. The experiment was laid out in a split plot design (SPD) with five replications at KVK and five at farmers' field.

Plant population/m² (65.03) was also recorded maximum in Zero till drill sown which was significantly higher than line sown seed drill method (62.90). Number of branch/plant (13.40) was recorded maximum in ZTD sown method, which was significantly higher over line sown with seed drill method (12.13). Number of pods/plant (61.13) was recorded maximum in Zero till drill sown method which was significantly higher over line sown with seed drill method (58.67). However, plant height was recorded maximum in seed drill sown method (45.31cm) which was no significant deference between ZTD sown method (45.12cm). No of grain/pod (1.64) and test weight (25.22 g) were recorded maximum with ZTD sown method but there is no significant deference with seed drill sown method in both characters. Days taken to maturity (122.93) were recorded maximum in Seed drill sown method and significantly higher over ZTD sown method (119.40). Biological yield in ZTD (3016.23kg/ha) was 3.95% higher than seed drill sown methods. Similarly, the grain yield (1576.67 kg/ha) in ZTD was 3.99 % higher compared to line sowing with seed drill. Straw yield (1439.57 kg/ha) in ZTD was 3.98% more over seed drill sown method. However, harvest index not significantly influenced by ZTD and seed drill sown method. Gross return, net

return and benefit-cost ratio recorded maximum with ZTD sown method. Maximum gross return was recorded with ZTD sown method (Rs. 65842.93/ha) was significantly more over seed drill sown method (Rs.62821.07/ha). Similarly, net return was also recorded significantly higher with (Rs.49789.60/ha) over seed drill sown method (Rs.44267.73/ha). B:C ratio recorded maximum with ZTD sown method (4.13) which was significantly higher over seed drill sown method (3.40). Plant height of PL-08 (48.28cm) was significantly higher over HUL-57 (44.26cm) and PL-06 (43.12cm). Plant population at harvest stage was recorded higher with PL-08 (70.60) was significantly higher over HUL-57 (66.65) and PL-06 (54.65). Number of branch/plant recorded maximum in PL-08 (14.75) which was significantly higher over HUL-57 (13.30) and PL-06 (10.25). Number of pods/plant (66.40) in PL-08 was significantly higher over HUL-57 (62.90) and PL-06 (50.40). Number of grain/pod was also recorded maximum with HUL-57 (1.7) being at par with PL-08 (1.69) and both were significantly more over PL-06 (1.51). However, test weight was recorded maximum in PL-06 (32.17g) was significantly higher over HUL-57 (22.71g) and PL-08 (17.86). Days taken to maturity (128.60) were significantly more in PL-08 being at par with HUL-57 (127.40) both were significantly higher over PL-06 (107.50) at maturity. Biological yield (3262.50 kg/ha), grain yield (1701.00 kg/ha) and straw yield (1561.50 kg/ha) recorded higher with PL-08 being at par with HUL-57 biological yield (3168.15 kg/ha), grain yield (1662.75 kg/ha) and straw yield (1503.90 kg/ha), which were significantly more over PL-06 biological yield (2446.05 kg/ha), grain yield (1275.45 kg/ha) and straw yield (1170.60 kg/ha). Biological, grain and straw yields were 33.37, 33.39 and 33.39%, more in PL-08 and 29.52, 30.36 and 28.47% in HUL-57 than PL-06, respectively. However, HI in three varieties was statistically similar. Maximum gross return (Rs 78246.00/ha), net return (Rs 61176.00/ha) and benefit cost ratio (4.61) recorded with PL-08 being at par with HUL-57 gross return (Rs 76486.50/ha), net return (Rs 59416.50/ha) and benefit cost ratio (4.52) both were significantly more over PL-06 gross return (Rs 38263.50/ha), net return (Rs 20493.50/ha) and benefit cost ratio (2.16).

Key words: Lentil, Variety, Method of establishment

ADSORPTION AND DESORPTION OF ZINC IN SOIL AND ITS IMPLICATION IN PLANT NUTRIENT

RAJENDRA BAIRWA, MAMTA, AKANKSHA, RAMCHANDRA KUMAR, SNEHA,

Dipti Kumari, Nisha Kumari, Pallavi Bharti, Department of Soil Science and Agricultural Chemistry, BIHAR AGRICULTURAL UNIVERSITY, SABOUR, BHAGALPUR- 813210

Zinc is an essential element (or nutrient) for plant as well as animal, that is mostly required micro plant nutrient out of total. Zn act as a catalyzing, and necessary for triptophane, a precursor amino acid of indol-3-acetic acid (IAA), a growth promoting plant hormone (Mengel and Kirkby, 2001). Zn consist in soil as available form only near about 0.1 to 0.6 ppm but in earth crust consist near about 71 ppm. Zn availability mostly depended on pH, texture of soil, O.M., Fe and Al (hydr) oxides, submergence of soil, etc. Zn availability mostly regulated through adsorption-desorption on soil (or adsorbent). P can reduces the Zn availability to plant by making a complex i.e. ZnHPO_4 together. Soil encase higher amount of CaCO_3 , high pH, addition of phosphatic fertilizers to soil, etc. These are favorable parameters for adsorption of Zn to soil. Adsorbed Zn can extracted by 0.005 M DTPA, 0.1 HCl, 0.5 M CaCl_2 and 1 M MgCl_2 extractants. The desorption of Zn from the adsorbed soil Zn through these extractants and having different power to desorbed Zn as $0.5 \text{ M CaCl}_2 > 1 \text{ M MgCl}_2 > 0.005 \text{ M DTPA} > 0.1 \text{ HCl}$ (Das and Das, 2015). Acidic soils mostly having Fe and Al (hydr) oxides and are responsible for adsorption of Zn. A little sorption occurring pH value under 6.0 but virtually 100 % sorption occurring over a narrow pH range of 6.0 to 8.0 (Gou W *et al.* 2018). Another fact is increase adsorption of Zn with clay content.

Key Words: Adsorption, Desorption, Zn-PO_4^- -complex etc.

EFFECT OF PUSA HYDROGEL ON PHENOLOGY OF RICE (*ORYZA SATIVA* L.) AT VARIOUS GROWTH STAGES IN SANDY LOAM SOILS OF WESTERN UTTAR PRADESH

RAJENDRA KUMAR, ADESH SINGH AND R.K. NARESH

Rajendra Kumar Department of Agronomy, College of Agriculture SVPUA&T, Modipuram, Meerut, Uttar Pradesh, India. Adesh Singh Department of Agronomy, College of Agriculture SVPUA&T, Modipuram, Meerut, Uttar Pradesh, India. R.K. Naresh Department of Agronomy, College of Agriculture SVPUA&T, Modipuram, Meerut, Uttar Pradesh, India.

A field experiment was conducted during *kharif* season of 2016 at Crop Research Centre (Chirori) of **Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P.) India**. The soil of the experimental field was well drained, sandy loam in texture and slightly alkaline in nature. It was low in organic carbon and available nitrogen but medium in available phosphorus and potassium. Rice (*Oryza sativa* L.) belongs to the genus *Oryza* and family Gramineae (Poaceae). The genus *Oryza* is distributed throughout the tropics and subtropics of the world. Rice is the second most widely consumed cereal in the world next to wheat. It is the staple food for two third of the world population. Over two billion people in Asia alone derived 80% carbohydrate, 7-8% protein, 3% fat and 3% fiber. It is occupying 163.20 million hectare of area, producing about 719.73 mt of rough rice with an average productivity of 4.41 t/ha (Anonymous, 2015). **In India, rice occupies an area of 43.95 mha with production and productivity of 106.65 mt and 2.4 t/ha, respectively.** In view of Agriculture specific requirements, scientist at Indian Agriculture Research Institute (IARI), New Delhi,

developed a granular product called Pusa Hydrogel (Synthetic polymer), which is able to absorb and hold 80-180 times of its volume of water for a long time. This technology is suited for farmers growing crops under rainfed and limited water availability areas. Pusa hydrogel (1.5 kg/acre) was applied in rice as fine granules, mixed with soil (1:10 w/w) or mixed with recommended dose of basal fertilizer application and it incorporating into the soil. The moisture conservation practice was recorded significant difference in plant height, dry matter accumulation, relative water content and chlorophyll content at all the stages of crop growth. The application of pusa hydrogel @ 1.5 kg/acre was recorded 3.67%, 1.64% and 4.35% respectively, more plant height (cm) and increased in dry matter production (g/m^2) was 1.8, 43.6 and 57.7 respectively, it was also recorded slightly increased in relative water content (%) and chlorophyll content (SPAD value) at all the stages of crop growth over no application. Application of pusa hydrogel @ 1.5 kg/acre in rice increased the growth at all the stages of crop growth over no application because it is a good synthetic polymer, which was used to conserve the 80 to 180 times more moisture and it helps into the regulating the metabolic activity of the plant under the moisture stress conditions as under treated plots over the control. .

AGRONOMIC TECHNIQUES IN NATURAL FARMING

RAJENDRA KUMAR, R.K. NARESH AND MOHAN LAL

Rajendra Kumar Department of Agronomy, College of Agriculture SVPUA&T, Modipuram. Meerut, Uttar Pradesh, India., R.K. Naresh Department of Agronomy, College of Agriculture SVPUA&T, Modipuram. Meerut, Uttar Pradesh, India., Mohan Lal Department of Agronomy, College of Agriculture SVPUA&T, Modipuram. Meerut, Uttar Pradesh, India.

Natural farming is an ecological farming approach established by **Masanobu Fukuoka (1913)**, a Japanese farmer and philosopher, introduced in his book *the "One-Straw Revolution"* (1975). Fukuoka described his way of farming as *shizen noho* in Japanese. It is also referred to as **"the Fukuoka Method"**, **"the natural way of farming"** or **"do-nothing farming"**. Natural farming emphasises on efficient use of on-farm biological resources and enrichment of soil with the use of Jeevamrutha to ensure high soil biological activity. Natural farming eliminates chemical fertilizers and pesticides and would help to reduce ocean acidification and marine pollution from land-based activities (Tripathi *et al.*, 2018). In India, Subhash Palekar reported four aspects that are related to ZBNF viz., *beejamrutham*, or microbial coating of seeds using cow dung and urine based formulations, *jeevamrutham*, or the application of a concoction made with cow dung, cow urine, jaggery, pulse flour, water and soil to multiply soil microbes, mulching or applying a layer of organic material to the soil surface in order to prevent water evaporation and to contribute to soil humus formation and *waaphasa* or soil aeration through a favorable microclimate in the soil. Use of Bijamrutha for seed/planting material treatment and Jeevamrutham for soil treatment and foliar spray are important components. Jeevamrutham has been found to be rich in various beneficial micro-organisms. Application of jeevamrutham @ 500 l ha⁻¹ is sufficient for one application, it is applied three times at one month interval during the crop season. It can be applied through irrigation water by flow, by drip and sprinkler or even by drenching of mulches spread over the field or under the tree basin (Naresh *et al.*, 2018). The natural farming now a day is more beneficial as compared to modern Agriculture because of the unjudicious use of chemical fertilizers and pesticides. The population of beneficial microbes is decreasing day by day. The natural farming might also increase the organic matter level into the soil because of efficient utilization of crop residue left on the surface of soil. The naturally grown products are more qualitative and fetch more price than the conventionally grown product.

PHYSIOLOGICAL VARIATIONS IN *DRECHSLERA SETARIAE* CAUSING LEAF SPOT DISEASE OF PEARL MILLET

RAJENDRA NASWA¹, S.L. GODARA² AND MANJEET SINGH³

¹Department of Plant Pathology, COA Bikaner, ²Professor and head, Department of Plant Pathology, COA Bikaner, ³Department of Plant Pathology, CCS Haryana Agricultural University, Hisar

Pearl millet is fourth most important cereal after crops like rice, wheat and sorghum and locally known as *bajra*, *sajja*, *bhari*, *combo*, *ganti* or *kambam*, is an allogamous crop having protogynous nature. It belongs to the family in Poaceae. India is the largest producer of pearl millet, Rajasthan occupies first position in area and production in India. The pearl millet grains are very nutritious and staple diet of approximately 10 per cent of the population in India. Among the various diseases of pearl millet, leaf spot caused by the fungus *Drechslera setariae* has attained the status of the economically important disease. Maximum mycelial growth of *Drechslera setariae* was reported on sucrose as compared to glucose, fructose and maltose. The pathogen *Drechslera setariae* having significantly better growth on three nitrogen sources viz., ammonium chloride, L-arginine and L-alanine, compared to glutamic acid. Among the tested nitrogen sources glutamic acid was found at least supportive to the mycelial growth of the pathogen. The maximum mycelial growth of pathogen was observed at 25 °C and minimum mycelial growth was recorded at 35 °C temperature. Similarly optimum mycelial growth of pathogen was found at pH 6.5. These findings showed good growth of pathogen over a range of pH 6.0 to 8.0. These findings will be helpful in understanding the epidemiology of the pathogen and further developing strategies for the control of leaf spot of Pearl millet.

PERFORMANCE OF CERTAIN NOVEL INSECTICIDES AND BIO PESTICIDES AGAINST STEM BORER SCIRPOPHAGAINCERTULUAS (WALKER) IN RICE**RAJENDRASINGH¹, D. K. SHRIVASTAVA², DEEPAK KUMAR¹***1. Department of Entomology, Sardar Vallabhbhai Patel University of Agri. & Tech., Meerut- 250 110, 2. Council of Science and Technology, Lucknow-226018 (U.P.)*

All the treatments were recorded significantly higher yield than untreated control (31.75 q/ha). The results of paddy yield depicted in table 3, showed that the plots treated with fipronil 0.3 GR @ 25 kg/ha gave the highest yield (45.56 q/ha), followed by cartap hydrochloride 50 SP @ 1kg/ha (43.01 q/ha), and imidacloprid 17.8 SL @ 200 ml/ha (42.35). In terms of economics the higher net return was obtained with the treatment of fipronil 0.3 GR @ 25 kg/ha (7.3) followed by cartap hydrochloride 50 SP (6.03) and imidacloprid 17.8 SL @ 250 ml/ha (5.48). The average increase in paddy yield over the control ranged from 5.01 to 11.26 q/ha under different treatments. The results revealed that the plots treated with fipronil 0.3 GR @ 25 kg/ha 5SC had the lowest dead hearts / white ears damage maximum paddy yield, and also gave maximum net return. Hence, the farmer of this zone could apply fipronil 0.3 GR @ 25 kg/ha along with alternate of cartap hydrochloride 50 SP @ 1kg/ha (45.56 q/ha), chlorpyrifos 20 EC and egg parasitids *Trichogramma japonicum* 1.0 lakh/ha for the effective management of YSB in rice crop.

SEASONAL INCIDENCE OF SCIRPOPHAGAINCERTULAS (WALKER) ON PADDY.**RAJENDRASINGH¹, D. K. SHRIVASTAVA², DEEPAK KUMAR¹***1. Department of Entomology, Sardar Vallabhbhai Patel University of Agri. & Tech., Meerut- 250 110, 2. Council of Science and Technology, Lucknow-226018 (U.P.)*

The incidence of yellow stem borer, *Scirpophaga incertulas* (Walker) showed that it was recorded on 31st standard week for the first time and continued till Third week of September i.e. 38th standard week. The infestation of stem borer recorded as dead heart ear heads ranged from 4.85 to 10.55 per cent and white ear head showed that it was recorded on 38th standard week for the first time and continued till second week of October i.e. 42th standard week ranged from 6.59 to 9.48 per cent during the crop season i.e. Kharif 2015-16. The incidence was lowest during the month of July which varied between 4.8 to 9.65 per cent. During the standard week in month of 38 September to October temperature range was 29.47 to 26.47°C, and the relative humidity was 64.89 (Evening) to 94.40 (Morning) and rainfall was 3.84 mm. During this period the weather parameters i.e. temperature, relative humidity and rainfall ranged 29.47 to 26.47°C, 73.53 to 79.64 per cent and 0.0-3.84 mm, respectively. The activity of stem borer suddenly decreased in the last week of October.

GENETIC PARAMETERS OF GRAIN YIELD AND IRON (FE) AND ZINC CONTENT IN PEARL MILLET [Pennisetum glaucum (L.) R. BR.] UNDER VARYING ENVIRONMENTAL CONDITIONS**RAJESH C. JEETERWAL¹, L.D. SHARMA² AND ANJU NEHRA³***^{1&2}Division of Plant Breeding and Genetics, Rajasthan Agricultural Research Institute (SKN Agriculture University), Jaipur (Rajasthan) India, ³Department of Plant Breeding and Genetics, College of Agriculture (RVSKVV, Gwalior), Indore*

Genetic analysis was studied in diallel fashion excluding reciprocals for grain yield and iron and zinc using ten diverse inbreds in pearl millet. Genetic components analysis revealed that additive-dominance model fitted for all the characters in all the environments, both additive (D) and dominance (H_1 and H_2) components were significant for both the characters with seed yield. However, relative magnitude of dominance component (H_1 and H_2) was higher than additive component for all the characters indicated preponderance of dominant gene action. The ratio of mean degree of dominance as measured by $(H_1/D)^{1/2}$ was more than unity in all the environments indicating over dominance. The value of $(H_2/4H_1)$ was less than 0.25 indicating asymmetric distribution of positive and negative alleles. The ratio of dominant to recessive alleles was more than unity in all the environments indicating accumulating of dominant genes. Narrow sense heritability estimates were of low to high magnitude for different traits. Heritability estimates (ns) were high 0.303 in E_2 and 0.528 in E_3 for Fe content and 0.116 in E_1 and 0.117 in E_3 for grain yield per plant. This is suggesting that selection for these traits would lead to rapid genetic improvement. The preponderance of non-additive gene effects of grain yield and its component traits in parents indicated that, heterosis breeding would be practically feasible in pearl millet crop.

Key words: Pearl millet, gene action, Additive, Non-additive variance, heritability, *Pennisetum glaucum***ADVANCE TECHNIQUES FOR IDENTIFICATION OF SEED BORNE DISEASES*****RAJESH SAINI, VIVEK AND VIKAS****Department of Plant Pathology Chaudhary Charan Singh Haryana Agricultural University*

Seed borne disease refers to the particular plant diseases that are transmitted by seed. In some cases the transmission on seed is

insignificant compared to the population of disease organisms that exist in soil or on weed species. In other cases, the transmission on seed is the primary means by which a disease spreads. While we are cautious about any type of disease on seed, it is this latter set of diseases that we must be most vigilant in controlling. Planting infected seed may result in a widespread distribution of disease within the crop, and an increased number of initial infection sites from which the disease can spread. As an example, consider the development of ascochyta blight in a chickpea crop. Since there is a high rate of seed-to-seedling transmission of this disease, even a small percentage of infected seed can result in significant seedling infection in the field. For a seed lot with 0.1 per cent ascochyta infection (one infected seed in 1,000 seeds) and a planting density of three to four plants/ft.², 175 infected seedlings per acre could potentially result. This is a substantial amount of early infection for such an aggressive disease. The diseases that are caused by fungal pathogens which persist (survive) in the soil matrix and in residues on the soil surface are defined as soil borne diseases. Thus the soil is a reservoir of inoculums of these pathogens, the majority of which are widely distributed in agricultural soils. Diseases of plants are caused primarily by three types of pathogens: bacteria, fungi, and viruses. Despite that fungi comprise the largest group of pathogens, the bulk of seed-specific diseases are caused by bacteria or viruses. This is due to the fact that bacteria and viruses are more adept at entering and then traveling through the veins of the plant, a phenomenon known as 'systemic infection,' and from the vascular system may make their way into the developing embryos of seeds. It is recommended to have seed tested at an accredited laboratory to assess the levels of seed-borne diseases. Commercial laboratories can test pulse seed to determine the level of seed-borne fungi that cause ascochyta blight, anthracnose, botrytis seedling blight and grey mould, and Sclerotinia. A parallel test for germination will indicate whether seed quality has been affected by such factors as immaturity, disease, mechanical injury and chemical damage. Testing for vigour may also be beneficial, as it serves as an indication of how seed will respond in less than ideal growing conditions. The best way to ensure success of a disease-management program is to adapt it to the diseases expected and to use integrated disease-control measures. Among these measures are resistant or tolerant varieties, crop rotations, fungicides, nematicides, and suggested agronomic practices. The success of any one or all of these measures may depend on how carefully you scout your crops. Because periodic scouting increases the likelihood that disease controls will be applied properly, it can help prevent loss through disease and unnecessary use of pesticides.

INTEGRATED NUTRIENT MANAGEMENT (INM): NEED OF THE PRESENT AGRICULTURAL ERA.

RAJNISH YADAV¹, RAJBEER SINGH², SIRAZUDDIN³, HUJJAT UL BALIGAH¹

¹Division of Soil Science and Agricultural chemistry, SKUAST-Kashmir, ²Division of Agronomy, SKUAST-Kashmir, ³Division of Agronomy, GBPUA&T, Pantnagar

The notion of sustainability as an ambition has become extensively accepted but the prevailing agricultural paradigm still believes high yield and reduced environmental impact being in clash with one another. During the past decades, the 3.4-fold increase in agricultural food production can be partly attributed to a 37-fold increase in N fertilization and a 91-fold increase in P fertilization, but the environment costs have been very high. New advances for sustainability of agriculture and ecosystem services will be needed during the upcoming years to improve nutrient use efficiency (NUE) while increasing crop productivity and reducing environmental risk. Integrated nutrient management (INM) based on numerous research studies has been advocated to farmers because the need for continued increase in agriculture production and productivity requires growing application of nutrients and the present level of fertilizer production in India is not enough to meet the entire plant nutrient requirement and moreover, neither the fertilizers nor the organic sources in isolation can achieve sustained production under intensive cropping. In INM approach, the key components comprise (1) optimizing nutrient inputs by taking all possible nutrient sources into consideration, (2) matching nutrient supply in root zone with crop requirements spatially and temporally, (3) reducing N losses in intensively managed cropping systems, and (4) taking all possible yield-increasing measures into consideration. Recent large-scale application of INM for cereal, vegetable, and fruit cropping systems has shed light on how INM can lead to significantly improved NUE, while increasing crop yields and reducing environmental risk. The INM has already influenced global agricultural policy and international actions, and resulted in increasing food production with decreased climb of chemical fertilizer consumption at a national scale over recent years. The interactive advantage of combining organic and inorganic sources of nutrients in INM have proved superior to the sole use of these sources. The INM can thus be considered an effective agricultural model to ensure food security and improve environmental quality worldwide, especially in countries with rapidly developing economies.

POTENTIAL UTILITY OF MICRO-ORGANISM IN PEST MANAGEMENT

RAJPAL YADAV¹, TARAYADAV², AND ABHISHEK YADAV³

¹Dept. of Plant Pathology¹ and Entomology², Rajasthan Agricultural Research Institute, Durgapura, S.K.N. Agriculture University, Jobner; ³Dept. of Entomology, S.V.P.U.A. & T., Meerut

Microbial pathogen consists of disease causing organism. Microorganisms or their bioactive agents can be used as active substances and

therefore are referred as Microbial Pest Control Agents (MPCA). Microbial pathogens of insects are intensively investigated to develop environmental friendly pest management strategies in agriculture. In the present day plant protection scenario, development of resistance to chemicals and residue in higher trophic level are major hurdle in insect pest management. In the recent years biopesticides are replacing the chemicals pesticides to overcome the harmful effect of the chemicals on non-target organism. These natural entomopathogenic agents, which have specific modes of action, are generally considered safer as compared to conventional chemical insecticides. Baculoviruses are the only viruses being used as the safest biological control agents. They infect insects and have narrow host ranges. *Bacillus thuringiensis* is the most widely and successfully used bio-insecticide in the integrated pest management programs. Bt mainly produces crystal delta-endotoxin and secreted toxins. However, the Bt toxins are not stable for a very long time and are highly sensitive to solar UV. So genetically modified plants that express toxins have been developed and represent a large part of the phytosanitary biological products. Entomopathogenic fungi and particularly, *Beauveria bassiana* and *Metarhizium anisopliae* are also used for their insecticidal properties.

Key Word: - Entomopathogenic agents, modes of action, NPV.

ATTRACTION OF DIFFERENT COLORED STICKY TRAPS FOR MANGO HOPPERS

RAKESH KUMAR, KIRAN NEGI AND POONAM SRIVASTAVA

Department of Entomology, College of Agriculture, G.B.P.U.A&T, Pantnagar - 263145 (Uttarakhand)

Mango (*Mangifera indica* Linn.) is known as a very important and popular fruit in the world, due to its colour, delicious taste aroma and high nutritive value, is known as king of all fruits. This important fruit crop production is enormously handicapped by the ravages of insect pests from seedling to their maturity. Among the mango pests, mango hoppers *Idioscopus clypealis* (Lethierry), *Idioscopus nitidulus* (Walker) and *Amritodus atkinsoni* (Lethierry) (Hemiptera: Cicadellidae) are the most serious and widespread pests throughout the country. The present investigation was carried out at Horticulture Research Centre, Department of Entomology, G.B. Pant University of Agriculture and Technology, (Uttarakhand). For this experiment seven different colored sticky traps (*viz.*, yellow, light yellow, blue, green, white, brown and pink) were prepared by using tough construction colored paper size of 30x 21 cm². Then, a thin layer of polybutene insect gum was coated on the both sides of the paper. The sticky traps were hung vertically with the help of bamboo and rope under the canopy of mango tree at the height of 2 meters. Total number of colored traps was twenty one; seven colored sticky trap were replicated thrice (7x3=21). Data were recorded on 1, 3, 5, 7, 10 and 15 days after traps hanging. During this investigation period mean number of hopper trapped on sticky traps were recorded 1- 6.83. The result reveals that highest mean numbers of hopper were recorded in the yellow sticky trap followed by blue and white 6.83, 5.16 and 3.33 respectively. In case of brown and light yellow colored traps mean numbers of hoppers were recorded 2.33. While, the lowest mean number of hoppers was recorded 1.00 in pink and green colored traps. It could be concluded that yellow and blue colored sticky trap were found more attractive than pink and green colored traps. While, attraction to other colored traps were less significant. Yellow and blue colored sticky trap can be used for monitoring mango hopper in the mango orchard.

Key words: Mango hoppers, sticky traps, polyisobutene and monitoring

SOIL AND WATER CONSERVATION FOR SUSTAINABLE AGRICULTURE

RAKESH KUMAR*, P.S. SANGWAN AND R.S. MALIK

Department of Soil Science, CCS Haryana Agricultural University, Hisar-125 004

Conservation of soil and water resources is important for sustainability of agriculture. Soil and water conservation are those activities which maintain or enhance the productive capacity of the land. Soil and water resources are under immense pressure due to ever increasing population and consequently these resources are being deteriorated. Soil erosion is one of the several major deteriorative processes which results in deterioration of the soil. Soil erosion leads to the significant loss of soil productivity and thus may results into desertification under sever conditions. Water and wind are the major agencies which are responsible of soil erosion. Deforestation, over-grazing, intensive cultivation, mismanagement of cultivated soils and intensive urbanization are major factors enhancing the soil erosion. For sustainable agriculture and environment, it is must to protect the soil resources against erosion. Different control measures should be adopted to protect the soil resources against erosion. The concept of soil conservation cannot be materialized without conserving and efficient use of water resources. It is therefore pre-requisite that soil conservation practices should be adopted. Soil conservation practice include soil management, crop management, engineering, range management and forestry operation. A variety of soil and water conservation measures are well known which ensure agriculture sustainability after these being implemented properly. Physical measures are structures built for soil and water conservation. Biological measures for soil and water conservation work by their protective impact on the vegetation cover. These measures slow soil erosion rate compared with an uncovered soil which shows in general a high soil erosion rate. Some possible agronomic measures are strip cropping, mix cropping, inter cropping, mulching, agro-forestry, contour ploughing etc.

Keywords: Soil erosion; Deforestation; Urbanization; Cropping.

HIGH DENSITY ORCHARDING IN CITRUS FRUITS

RAKESH KUMAR PANDEY^{1*}, ANKIT KUMAR PANDEY², K. KARUNA³, VED PRAKASH⁴ KULDEEP PANDEY⁵

^{1, 2, 3}Department of Horticulture (Fruit & Fruit Technology), Bihar Agricultural University, Sabour-813210, Bhagalpur, Bihar (India),

⁴Department of Agronomy, Bihar Agricultural University, Sabour-813210, Bhagalpur, Bihar (India) ⁵Division of Fruit and Horticulture Technology, Indian Agricultural Research Institute, Pusa, -110012, New Delhi

High density planting (HDP) technique is a modern method of fruit cultivation involving planting of fruit trees densely, allowing small or dwarf trees with modified canopy for better light interception and distribution and ease mechanized of field operation. HDP and meadow orcharding gives higher yield and returns per unit area because of increasing the no. of trees per unit area. It is possible by regular pruning and use of plant growth regulators to maintain the size and shape of the tree. HDP is one of the novel methods to achieve high productivity per unit area in citrus crops. High yield and high fruit quality in citrus can be achieved with a high-density orchard. Planting density is one of the most important factors in citrus which determine the yield of an orchard. The main motto of HDP is to get the trees into early bearing as soon as possible from a limited space. This is best accomplished by following proper training and pruning regime combined with a precocious rootstock for obtaining significant production. The important dwarfing rootstocks which are commercially used in citrus high density planting are flying dragon, troyer citrange and trifoliate orange. Kinnow can be grown in high density planting by using troyer citranges as a rootstock by spacing the plants at 1.8 x 1.8 m (3000 plants ha⁻¹). Through high density planting system in citrus one can obtain maximum and quality yield per unit area and also reduce the gestation period and increasing the productivity of the orchards. The selection of the system of planting in the orchard depends on topography, crop, variety, plant density and production technology to be followed.

Key words: Citrus, Dwarf, Orchard, Rootstock, Technology

CONSERVATION AGRICULTURE FOR IMPROVING WATER PRODUCTIVITY IN SEMI ARID REGION

RAKESH KUMAR^{*}, JOGINDER KUMAR², ARVIND KUMAR³, ANUPAMA RAWAT⁴ AND SOMA DEVI⁵

^{1,3,4}Ph.D. Research Scholar, Department of Agronomy, G.B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand-263145, ²Department of Soil Science and Agricultural Chemistry, ⁵Department of Agronomy, SKRAU, Bikaner, Rajasthan

Increasing human population and uncertainty, large variability in rainfall and long dry spell during the crop growing period are the major limiting factors for crop growth and improving water productivity in semi arid region. Agriculture water management interventions are considered the conservation agriculture (CA) is suitable practice to enhance crop yield, productivity and income in semi arid region. Conservation agriculture is considered an important in situ intervention strategy for improving crop and water productivity in climate smart agriculture. The three basic components of CA are: (A) zero or minimum tillage, (B) incorporation of crop residues on the soil surface and (c) diversification of crop. Minimum tillage reduces volume and velocity of surface runoff, leading to reduction in soil erosion and nutrient loss; incorporation of crop residues enhances soil water availability, reduces evaporation loss, improves infiltration by restricting surface runoff and reduces surface sealing from raindrop impact. Crop diversification reduces the risk of crop failure and is recognized as a cost-effective solution to build resilience into agricultural production system. Diversification also brings stability in soil fertility through cultivating legumes with cereals in rotation or intercropping system. Recent studies have reported that CA improved crop productivity by 20-120% and water productivity by 10-40%. On farm trials showed that the CA not only improved the crop yield, but also generated higher gross returns compared to farmers' practice. However, other studies reported no improvement or at some cases negative effects on crop yield by adopting such techniques.

COMBINING ABILITY ANALYSIS IN PUMPKIN (*CUCURBITA MOSCHATA* DUCH. EX POIR.) FOR SMALL SIZE, THICK FLESH, HIGH YIELD AND BETA CAROTENE CONTENT

R. KUMAR^{*}, V. RAJASREE¹, S. PRANEETHA¹, S. RAJESWARI² N. SAVITHIRI¹ AND K. JAYALAKSHMI¹

¹Department of Vegetable Crops, Horticulture College and Research Institute, TNAU, Coimbatore-641003, India, ²Centre for Plant Breeding and Genetics, Agriculture College and Research Institute, TNAU, Coimbatore-641003, India

Combining ability studies are more reliable as they provide useful information for the selection of parents in terms of performance of the hybrids and elucidate the nature and magnitude of various types of gene actions involved in the expression of quantitative traits. A line x tester mating design was used to study the combining ability for developing small size, thick flesh, high yield and beta carotene content varieties and hybrids in pumpkin according to consumer preferences. In India consumers prefer dark yellow color, round shaped fruit with thick and deep yellow internal flesh color which have high beta carotene and ascorbic acid content to alleviate the vitamin A deficiency problem. A study was undertaken using nine parents which include 6 lines and 3 testers during 2016-17 at Department of vegetable crops, Horticultural College & Research Institute, Tamil Nadu Agriculture University, Coimbatore to study the heterosis and

combining ability for yield and its contributing characters. Evaluation of parents based on per se and general combining ability (*gca*) effects revealed that the parents CO2, Rajasthan Local and Odisha Local excelled for small size, thick flesh with high yield and beta carotene content respectively. The hybrids viz., Rajasthan Local and Pusa Viswas had registered favourable values of mean and significant *sca* for yield and other important characters. Further these top performing F₁ hybrid can be tested in different seasons over different locations for assessing their stability for high yield and other important characters.

GREEN TECHNOLOGIES FOR THE EXTRACTION OF BIOACTIVE COMPOUNDS IN FRUITS AND VEGETABLES

RAKESH¹, NARENDRA SINGH²

¹*Division of agricultural chemicals, ICAR-IARI, New Delhi, India*, ²*Division of Fruits and Horticultural Technology, ICAR- IARI, New Delhi, India*

Bioactive compounds are extracted from natural sources and they have beneficial effects on human health. Fruits and vegetables are rich in bioactive compounds like carotenoids, phenolic compounds, Vitamin C, among others. Conventional extraction techniques generally require large amounts of organic solvents, high energy expenditure, and are time consuming, which has generated interest in new technologies that are referred to as clean or green technologies. Green extraction processes is to achieve a faster extraction rate, more effective energy use, increased mass and heat transfer, reduced equipment size, and a reduction in the number of processing steps. The following modern green extraction techniques-supercritical fluid extraction (SFE), pressurized liquid extraction (PLE), microwave assisted extraction (MAE), ultrasound-assisted Extraction (UAE), pulse electric field assisted extraction (PEF), high hydrostatic pressure (HHP), natural deep eutectic solvents (NADES), enzyme assisted extraction (EAE) are efficient and environment friendly compared to conventional extraction methods like decoction, maceration, soxhlet extraction, hydrodistillation for bioactive compound extraction. Cyclodextrins (CDs) are known molecular encapsulators and the use of CDs enhanced the extraction of pomegranate polyphenols by 20%. Efficient extraction of antioxidant compounds from blackberry (*Rubus* sp.) bagasse using supercritical CO₂ assisted by ultrasound is also reported. Extraction of juice and polyphenols from citrus fruits has been improved by Pulsed electric field treatment. So the green extraction technologies can be considered as a new concept to meet the challenges of the twenty-first century, to protect both the environment and consumers, and in the meantime to enhance competition of industries to be more ecological, economical, and innovative.

Key words- Antioxidant, bioactive compounds, extraction, techniques.

RESPONSE OF DRIP IRRIGATION METHOD OF GROWTH AND YIELD ON CHILLI CROP CHILLI (*CAPSICUM ANNUUM*)

***RAM KUMAR, GURCHARAN SINGH AND CHANDRABHAN**

Assistant Professor and Students, School of Agricultural Sciences and Engineering, IFTM University, Moradabad-244102

Drip irrigation is an irrigation method that saves water and fertilizer by allowing water to drip slowly to the roots of plants, either onto the soil surface or directly onto the root zone, through a network of valves, pipes, tubing, and emitters. It is done through narrow tubes that deliver water directly to the base of the plant. The study was conducted in the research farm in the field located at **IFTM University Moradabad**, during the period of 2015 to 2016 Rabi season. The study area of 0.006 between Field 280 50' 33.826" N latitude, 780 46' 48.535" E longitude studies was conducted during the Rabi season of 2015 to 2016. E. The results shown the drip irrigation system of fruit characteristics recorded after every picking and the average values are expressed under various treatments of fruit yield and quality. At harvesting time, samples of green pepper fruits were randomly harvested from each plot to measure fruit length and fruit diameter. In addition, total weight of fruits in each treatment were recorded by harvesting pepper fruits twice weekly and then the total yield as Kg/fed., was calculated. The maximum yield of crop 900 gm/plant and minimum of yield 600 gm/plant and total yield 52270 gm (52.270 kg). The water use efficiency of the crops has to be increased in order to reduce the water loss from the field and drip irrigation system is considered as the most effective micro irrigation method, as water is applied directly into soil at the crop root zone.

OFF-SEASON CULTIVATION OF VEGETABLE CROPS

RAM LAKHAN MEENA*, M.L. MEENA**

Department of Horticulture, Babasaheb Bhimrao Ambedkar University, Lucknow

Protected cultivation of vegetables offers distinct advantages of quality, productivity and favourable market price to the growers. Vegetable growers can substantially increase their income by protected cultivation of vegetables in off-season as the vegetables produced during their normal season generally do not fetch good returns due to large availability of these vegetable in the markets. Off-season cultivation of cucurbits under low plastic tunnels is one of the most profitable technologies under northern plains of India. Walk-in tunnels are also suitable and effective to raise off-season nursery and off-season vegetable cultivation due to their low initial cost. Insect proof net houses can be used for virus-free cultivation of tomato, chilli, sweet pepper and other vegetables mainly during the rainy

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

season. These low cost structures are also suitable for growing pesticide-free green vegetables. Low cost greenhouses can be used for high quality vegetable cultivation for long duration (6-10 months) mainly in peri-urban areas of the country to fetch commensurate price of produces. Poly-trenches have proved extremely useful for growing vegetables under cold desert conditions in upper region of Himalayas in the country.

IMPACT OF RICE HUSK BIOCHAR ON WHEAT GROWTH PARAMETER

REMA BARMAN*, GEETA KANDPALI

**Department of Agronomy, School of Agriculture, Lovely Professional University, Phagwara, 144411, Punjab, India, 1Assistant Professor, Department of Agronomy, Lovely Professional University, Phagwara, 144411, Punjab, India*

Wheat (*Triticum aestivum*) is one of the most important cereal crop whole over the world which is used as a staple food. The biochar is made by biomass via pyrolysis under thermal decomposition. It is charcoal which is used as reclamation of soil's physical condition. Apart from this, biochar can also enhance soil fecundity under low pH condition and also expand the agricultural production and provide protection against some foliar and soil-borne diseases. Due to the presence of more C: N ratio, rice husk not easily degradable to the soil. Biochar application is one of the best solutions for improvement of wheat production. This is the only one alternative source of applying essential nutrients to the plant. It is applied to soil in the form of biochar. The experiment was carried out in Lovely Professional University, Phagwara at experimental field to check out the growth and development of wheat in biochar applied soil. On the basis of field trial, biochar may significantly improve the different morphological parameters like plant height, no. of panicle & panicle length were measured at 45 DAS, 60 DAS, 75 DAS, & 90 DAS. For Further research needs to consecutively understand about the biochar interaction with soil.

KEY POINTS: Biochar, crop, charcoal, nutrient, soil, wheat.

EFFECT OF SOIL MICROBES ON IMPROVING PHYSICAL PROPERTY OF SOIL.

RAMJEET YADAV*, SHRIMAN KUMAR PATEL, AVINASH SARIN SAXENA AND AJEET KUMAR

Department of Soil Science & Agricultural Chemistry, Bihar Agricultural University, Sabour, Bhagalpur, Bihar, India - 813210

Soil physical conditions play an important role in retention of water and nutrients in the soil and eventual availability to plants. Soil micro-organisms like bacteria, fungi and mycorrhiza play an important role in improving soil structure by promoting the formation of soil aggregates and pores within. Not only are the soil physical conditions influenced by soil microorganisms, but the demography of soil microorganisms is also influenced by soil physical conditions. Soil aggregate stability is a multifaceted process and is an indicator of many aspects of soil structure including soil water regimes and nutrient availability. The stability of aggregates is controlled by soil physical and microbial community properties and plant roots. Fungal cells release mucilaginous exudates which are mainly composed of extracellular surface polysaccharides; cell wall polysaccharides and somatic or intracellular polysaccharides located inside the cytoplasmic membrane. Extracellular polysaccharides are mainly responsible for the formation of aggregates, which are beneficial for improving porosity and aeration in soil. Bacteria release exo-polysaccharides that form organo-mineral complexes which help in binding soil particles into aggregates. During bacterial growth, extracellular polymeric substances are produced in the form of peripheral slime polymers into the soil solution. These are negatively charged polysaccharides, polyuronic and amino acids with adhesive properties capable of making bond between clay particles in order to form aggregates. These aggregates adhere together to form macro aggregates and thus increase inter-particle cohesion. Additionally, AM Fungi can also alter soil microbes in its surrounding environment as well as the rhizosphere of host plant which are probably involved in soil aggregation. These contributions of AM fungi are often entangled together developed a model for soil aggregation where their simulated results indicate that AM fungi, organic matter and plant roots are key contributors to aggregate formation in soil. They also observed that this group of fungi plays an important role in stabilization of soil aggregates. Thus the soil microbes do improve the physical properties of soils as well as the fact that soil physical conditions influence the soil microbial population in native ecosystems.

EFFECT OF CROP RESIDUE AND NUTRIENT MANAGEMENT ON SOIL PHYSICAL PRODUCTIVITY UNDER RICE-WHEAT CROPPING SYSTEM

RAMTEKE PR^{1*}, PATLE PN²

^{1*}Punjab Agriculture University, Ludhiana (Punjab) 141004, ²Panjabrao Deshmukh Krishi Vidyapeeth, Akola (MH) 444104

Ricewheat is a major cropping system in north-west India because of the availability of high-yielding rice and wheat varieties and favourable climate conditions. Continuous cropping of ricewheat with increase in rate of fertilizer use & due to alternate tillage practices in this system, the problem of poor aeration and compaction have started emerging which may led to loss of soil productivity and reduction of soil water holding capacity & soil structural stability. Despite of high fertilizer use present productivity potential of

ricewheat cropping system in this region is under threat because of deteriorated physical and hydraulic properties and low organic carbon content of the soil. Soil physical productivity i.e. soil physical properties in relation to crop yields is significantly affected by nutrient and organic residue management. Crop residues are important natural resources, and recycling of these residues improves the soil physical condition of soil. Crop residues are generally regarded as a waste but when utilize properly, they improve the soil condition. There are several management options available, like burning, removal, incorporation, surface retention & mulching. Among these, most of the farmers resort to burning of residue to avoid interference with machinery while planting of next crop, but this result in deterioration of soil hydraulic properties as well as identified as a major health hazard. Effects of incorporation, surface retention and mulching have been widely documented by researchers and found to be effective in improving physical properties of soil in long run due to the presence of carbon pool. However, effect of residue incorporation on soil physical properties is mainly depend on soil texture. Mulching improves the soil physical properties up to certain amount beyond which the increments are considerably small. Soil and location base residue management option will help in conservation of soil, water and agricultural resources to achieve economic, ecological and socially sustainable agricultural production. Crop residues have tremendous potential to improve soil physical condition by improving organic carbon, biotic activity, aggregation status, soil bulk density, total porosity, hydraulic properties, prevents surface sealing and crusting, allows more water to infiltrate by cutting down the runoff and soil loss.

Keywords- Crop residue, management options, soil physical properties

IMPACT OF BORON AND ZINC METALOSATE FOLIAR SPRAY ON POMEGRANATE FRUIT NUTRIENTS AND QUALITY

RAMYA, S.H., AND SUBBARAYAPPA, C.T

Department of Soil Science and Agricultural Chemistry, University of Agricultural Sciences, GKVK, Bengaluru-65

Boron and zinc metalosate are the amino acid based liquid boron and zinc fertilizers and hundred percent soluble in water. Inoder to study the influence of boron and zinc metalosate foliar spray on major (N, P and K), secondary (Ca, Mg and S), micronutrients (Zn, Cu, Fe, Mn and B) and quality parameters (TSS, total sugars and titratable acidity) of pomegranate fruit present work was carried out in four year old pomegranate plant (cv. Bhagwa) with seventeen treatments and three replications under randomised block design. Significant increase in the major nutrient like nitrogen, phosphorus and potassium content in the pomegranate fruit was recorded and it was varied from 1.51 to 2.40, 0.13 to 0.64 and 0.95 to 1.64 %, respectively. Among different treatments significantly higher NPK (2.40, 0.64 and 1.64 %) content in the pomegranate fruit was recorded at treatment T₁₅ (NPK+ 0.017% B through boron metalosate+ 0.050 %Zn through zinc metalosate). However, the treatments did not have significant effect on calcium and magnesium content of the fruit expect sulphur content. Non significant difference was observed among the treatments with respect to zinc, iron, copper and manganese content and it was ranged from 24.87 to 26.73, 57.49 to 61.22, 5.74 to 6.44 and 25.25 to 27.62 mg/kg, respectively. However, the boron content in the pomegranate fruit was enhanced significantly and it was recorded between 29.21 to 42.66 mg/kg. Among treatments, treatment T₁₃ which consists of foliar application of boron @ 0.051 % through boron metalosate recorded highest boron content of 42.66 mg/kg compared to rest of the treatments.

Keywords: Boron metalosate, Zinc metalosate, Pomegranate, Major, Secondary, Micronutrients content in fruit and Quality parameters

DOUBLING OF FARMERS INCOME THROUGH NANO-ZEOLITE BASED TECHNOLOGY

¹RANJEET SINGH BOCHALYA, ¹LALICHETTI SAGAR, ¹KAPILASHIV BAZGALIA, ²KAMAL KANT,

¹Division of Agronomy, Sher-e Kashmir University of Agricultural Scirences and technology, Jammu, ²School of Natural Resource Management, CPGS (CAU), Umiam, Meghalaya

Nitrogen is the “kingpin” of nutrient kingdom and its management is a critical issue across the globe. The atmosphere carries about 78% N₂ which is hardly possible for plants use. The biological N fixers facilitate N cycling in agro-ecosystems. In mineral soil, organic matter possesses 98% N and more than 90% of the arable soils are found deficient in available N. Since major portion of added N got lost through leaching, volatilization and denitrification. The N use efficiency of crops hardly exceeds 30-35%. The applied N through fertilizers undergoes transformation processes. These transformation processes make N management very complex and quite difficult to improve the N use efficiency. Inorder to improve NUE several methods are in practice such as use of slow release nitrogenous fertilizers but the NUE enhance due to these fertilizer technologies are limited. To resolve this situation Nano-technology appears to be a light of hope. Nanotechnology deals with manipulation of materials at atom level, molecular and macromolecular scales which operates at 100 nm. It increases surface area to volume ratio altering mechanical, thermal and catalytic properties of fertilizer materials. The nano particle which is highly compatible to load with presently available synthetic fertilizer and showed positive results on growth and yield of several crops Nano-zeolite. These particles easily carries the fertilizer that is fabricated into the plant system improving its NUE to its maximum thereby reducing excess use of chemical fertilizers. This technology seems to be a lime light for golden era wherein farmers income gets doubled.

INCREASING CHICKPEA QUALITY AND VIGOUR POTENTIAL SUSTAINABILITY USING ORGANIC AND NATURAL RESOURCES**RANVIR***Department of Agronomy, Navsari Agricultural University, (Navsari) Gujrat-396450, India.*

The chickpea (*Cicer arietinum* L.) as a healthy vegetarian food has an important role in human food. It is a cheap source of high quality protein in the diets of millions of people in developing countries. In addition to proteins, it is a good source of carbohydrates, minerals and trace elements [19]. Also chickpea play a key role in organic cropping systems. In such agro ecosystem with limited availability of nitrogen. The growing chickpea in crop rotation increases crop sustainability for the semi-arid region. Organic farming needs to be self-sufficient in nitrogen through the fixation of atmospheric di-nitrogen (N₂) by legumes crops. Green manures application to the soil is considered a good management practice in all agricultural production system because of increasing cropping system via sustainability by reducing soil erosion, improving soil physical properties. A major benefit of green manure and organic fertilizer is the increase organic matter of the soil. They help to recycle other nutrients on the farm. Phosphorous, potassium, calcium, magnesium, sulfur, and other nutrients are accumulated by green manures. During decomposition of organic matter, carbonic and other organic acids are formed as a by product of microbial activities. Organic acids react with insoluble mineral rocks and phosphate precipitates, releasing phosphates. Phosphorus is present as mineral deposits, which are a nonrenewable natural resource. Phosphate solubilizing bacteria are also known to increase phosphorus uptake resulting in better growth and higher yield of crop plants. both *Rhizobium* and phosphate solubilizing bacteria has increase number and size of nodulation, growth and yield in chickpea.

DETERMINATION OF ADOPTER CATEGORIES ON ADOPTION OF HYBRID RICE IN JAMMU DISTRICT**RASHIKA MAHAJAN, Y.S. BAGAL, L.K. SHARMA AND TARIQ IQBAL***Division of Agricultural Extension Education, SKUAST- Jammu, J&K, India*

All potential adopters of a new product do not adopt the innovation at the same time rather they adopt it over a period of time (Rogers, 2003) and on this basis, the degree to which an individual is relatively earlier in adopting the innovation, adopters can be classified into different categories. Development of adopter categories requires determination of the number of adopter categories, the percentage of adopters to include in each category, and a method to define categories. To find out the adopter categories of hybrid rice, a study was conducted in one randomly selected block of Jammu district. A total random sample of 70 respondents was interviewed using a semi-structured interview schedule. Majority of the farmers were of middle age (44-63 years) and studied upto matriculation. The average land holding of farmers was 1.92±2.61 ha. In the study area, adoption of hybrid rice was started in 2005 and maximum adoption was in 2012. Hybrid-6444 was the first hybrid variety adopted by 80% of the adopters irrespective of their year of adoption having an average yield of in their first year, with an average yield of 61.37 q/ha. There are many comparative benefits of hybrid rice reported by the farmers viz; more production, no lodging, early maturity and less water requirement but along with it many constraints were also perceived by the farmers in its cultivation such as more disease and insect pest attack and difficulty in harvesting and threshing, etc. The time variable allows us to classify the respondents into different adopter categories. In the study area, the adopters were plotted on the basis of innovativeness and on cumulative basis and they almost follows the normal curve and s- shaped curve. The percentages of adopter category found in the study area were approximately similar to that of Rogers in adopter categories, i.e., 2.86 percent innovators, 17.14% early adopters, 25.71% early majority, 37.14% late majority and 17.14% laggards. It is suggested that extension agencies have to provide information and remain in contact with farmers for early adoption of innovations.

Keywords: Adoption; hybrid rice; innovativeness; constraints; adopter categories**INFLUENCE OF CMS CYTOPLASM ON HETEROSIS IN HIGH YIELDING VARIETAL CROSSES IN *BRASSICA JUNCEAL*.****RASHMI¹, NEHA DAHIYA¹, DARSHANABISHT², RAM BHAJAN¹ AND USHA PANT¹**

¹Department of Genetics and Plant Breeding, College of Agriculture, G. B. Pant University of Agriculture & Technology, Pantnagar, Uttarakhand-263145, ²Department of Molecular Biology & Genetic Engineering, G. B. Pant University of Agriculture & Technology, Pantnagar, Uttarakhand-263145

The basic material required for development of hybrids is production of large number and perfected experimental hybrids to be evaluated in multi-location trials but since, Indian mustard (*Brassica juncea* L.) is self-fertilized crop, there is economical constraint in the form of hand emasculation and pollination. CMS based hybrids can be used to overcome this barrier and hence, therefore, number of CMS systems have been developed for exploitation of heterosis out of *ogu*, *mori* and 126-1 has been utilized to developed hybrids in India so far. The grey area or gap in study was found regarding the effect of CMS cytoplasm on heterosis achieved in CMS based hybrids compared to normal hybrids with only few studies reported so far. Therefore, in the present study *ogu* CMS based hybrids were compared

with normal hybrids made with similar high yielding varieties used as lines and testers for mid parent and better parent heterosis. A cursory view of estimated heterosis over mid-parent as well as over better parent showed a shift in direction of significant heterosis in the two sets of crosses, which varied with cross as well as with character. Such a change in mid-parent heterosis in either direction was observed for 16 crosses for number of primary branches; 11 for silique length; 10 for number of secondary branches; 9 for silique on main raceme while for rest of the characters 5 or less number of crosses were exhibited a such a shift. Similarly, better parent heterosis was also affected in same way in number of crosses for the characters under study. One cross *i.e.* Maya × PR-2006-14 did not show any directional change in both the types of heterosis. Results indicated that heterosis of parental lines with native cytoplasm may or may not remain intact after their conversion into CMS background. Thus, it can be inferred that heterosis of lines converted into CMS background will have to be re-examined for identification of potential crosses for commercialisation of CMS based hybrids. There also exists possibility of finding crosses with negligible or no effect of cyto-nuclear interactions due to reestablishment of harmonious interaction.

EFFECT OF NUTRIENTS, PLANT EXTRACTS AND FUNGICIDES ON ALTERNARIA BLIGHT OF TOMATO CAUSED BY *ALTERNARIA ALTERNATA*

RATAN LAL SHARMA¹, POOJA NAIN² AND YOGITA NAIN³

¹Department of plant pathology, SKNAU, Jobner (Jaipur), ²Department of soil science and agriculture chemistry, SKNAU, Jobner (Jaipur), ³Department of Plant Pathology, JNKVV, Jabalpur (MP)

Alternaria blight of tomato caused by *Alternaria alternata* is one of the major disease causing considerable yield loss. Hence, the present investigations was carried out in the laboratory as well as in the field during *zaid* 2017 and 2018, both at the Horticulture Farm, S.K.N. College of Agriculture, Jobner and Department of Plant Pathology, Sri Karan Narendra Agriculture University, Jobner, Rajasthan. Tomato (*Solanum lycopersicum* L.) ranks first among processing crops. Tomato is the world's second most consumed vegetable after potato. Alternaria blight of tomato caused by *Alternaria alternata* is one of the most important fungal diseases prevalent in tomato growing areas of India particularly in Rajasthan State and is considered as one of the limiting biotic factor for successful cultivation of tomato. Among seven nutrients tested, Copper sulphate gave maximum inhibition of mycelial growth (52.22 %) at all concentrations. In field experiment, two sprays of Copper sulphate (0.5 %) was found most promising in reducing the disease intensity (46.94 %) & increasing yield (45.52 %). Among seven plant extracts tested, *Allium sativum* clove extract gave maximum inhibition of mycelial growth (96.70 %) at all concentrations. In field experiment, two sprays of *Allium sativum* clove extract (10 %) at 15 days interval from disease initiation, was found most promising in reducing the disease intensity (58.16 %) & increasing yield (55.35 %). Among seven fungicides tested, Hexaconazole gave maximum inhibition of mycelial growth (98.81 %) at all concentrations. In field experiment, two sprays of Hexaconazole (0.2 %) at 15 days interval from disease initiation, was found most promising in reducing the disease intensity (79.74 %) & increasing yield (88.51 %).

PACKAGING TECHNOLOGY OF HORTICULTURAL CROPS

RAVI PRATAP SINGH AND ABHINAV KUMAR

Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad

The increasing demand for fresh and quality packaged food, consumer convenience and manufacturers concern for longer shelf life of the food products is driving the market for Global active and smart packaging technology for food Markets. Being perishable, fruits and vegetables require to be preserved until they are sold and used by consumers. This offers challenges in food preservation. The package must not only act as an inert barrier to the external environment but also resist respiration issues. Demands on package performance continue to increase as a result of market and social changes. Active packaging reduces the need for additional preservatives in perishable food stuffs. Thus the shelf-life is extended and the food stuffs maintain freshness longer and are mildly preserved. Packaging technologies with an aim to scavenge or absorb ethylene from the surrounding environment of packaged produce have also been developed. . Oxygen scavengers can be incorporated in the packaging system itself rather than being added as sachets or labels as seen above. The oxygen scavenger can be incorporated into crowns, cans and a variety of metal and plastic closures.

Keywords fresh and quality packaged, perishable food stuffs, shelf-life is extended etc.

EFFECT OF NUTRIENT MANAGEMENT ON GROWTH, YIELD AND ECONOMICS OF RICE (*ORIZASATAVAL*.)

RAVINDRA KUMAR AND VIRENDRA SINGH

School of Agricultural Sciences and Engineering, IFTM University, Moradabad-244102

The present investigation entitled “Effect of Nutrient Management on Growth, Yield and Economics of Rice (*Oriza satava L.*)” was conducted at Research Farm, School of Agricultural Sciences and Engineering, IFTM University, Moradabad in 2018 during Kharif season to evaluate the impact of continuous use of inorganic fertilizers on productivity, economics and soil fertility status. Growth parameter such as plant height, fresh weight and dry weight, no. of tiller per plant, leaf area, panicle length, no grains per panicle, weight of grains per panicle, test weight, sterility percentage, total yield and economics parameter. The differences in growth attributes were statistically alike between 100 % RDF with (T7). Sustainability of any system requires optimal utilization of resources such as water, fertilizer and soil. Apart from the economic considerations, the adverse effect of injudicious use of water and fertilizers on the environment can have far reached implications. There is a need to develop agro technologies, which will help in sustaining the precious resources and maximize the crop production, without any detrimental impact on the environment.

SCREENING OF GERMPLASM AND EVALUATION OF NEWER INSECTICIDES AGAINST WHITE FLY (*BEMISIA TABACI*) IN MUNGBEAN (*VIGNARADIATAL*.)

RAVINDRA NATH NIASHAD, R. B. SINGH VIJAY KUMAR, SURYA PRATAP SINGH AND GURDEEP SINGH

Department of Entomology, NDU&T, Kumarganj, Faizabad 224229

Mungbean is the third most important pulse crop of India after chickpea and pigeonpea. The nutritive value of mungbean is high and easily digestible protein with approximately 25-28% protein, 1.0-1.5% oil, 3.5-4.5% fibre, 4.5-5.5% ash, 62-65% carbohydrate, 9.1% water and vitamins on dry weight basis. Mungbean crop is raised in three seasons viz., *Kharif*, *Rabi* and *Zaid* which cultivated in about 2.71 million hectares with production of 1.19 million tonnes. In Uttar Pradesh, green gram is being cultivated on 0.078 million hectares that produce 0.051 million tonnes with an average productivity of 658 kg/ha. Among major problem known to limit the production of mungbean, incidence of insect-pests is one of the major constraints. Among these whitefly (*Bemisia tabaci*) is one of the most serious pest. The yield loss of mungbean due to whitefly reported as 30-70% in normal weather condition. None germplasm were free from whitefly, both at 50% flowering and 50% pod maturity stage. Lowest 0.90 per plant whitefly population was observed in PUSA 0672 at 50% flowering stage and 0.95 per plant whitefly population were observed in KM13-47, PUSA0672, PUSA0871, PUSA1331, PUSA1332, PUSA1441 and PUSA9531 at 50% pod maturity stage showed resistance (< 1 whitefly per plant) against whitefly. Studied on the field evaluation of newer insecticides against *B. tabaci* on mungbean carried out by using 6 insecticides, in which most effective treatment was Emamectin benzoate 5 SG @ 10 g a.i./ha followed by indoxacarb 14.5 SC @ 60 g a.i./ha, Profenophos 50 EC @ 500 g a.i./ha, Spinosad 45 SC @ 73 g a.i./ha and Novaluron 10 EC @ 30 g a.i./ha. Imidacloprid 17.8 SL @ 210 g a.i./ha.

BIO EFFICACY OF BOTANICALS AGAINST PULSE BEETLE (*CALLOSOBRUCHUS CHINENSIS* LINN.) IN STORED CHICKPEA UNDER AMBIENT CONDITION

RAVINDRA NATH NISHAD, RADHA BINOD SINGH AND RAVI SHANKER

Department of Entomology, NDU&T, Kumarganj, Faizabad (U.P.) 224229

The seed quality of chickpea is deteriorated by infestation of bruchid during storage, which is managed by using botanicals and insecticides as seed protectants. Bio-efficacy viz.; infestation, weight loss, seed moisture content, germination, vigour and insect mortality were effected at different level seed storage. Studies on “Bio efficacy of botanicals against pulse beetle (*Callosobruchus chinensis* Linn.) in stored chickpea under ambient condition” was carried out in the Department of Entomology, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad during 2016-17. Eight seed protectants viz., Neem leaf powder @ (5g kg⁻¹), Nimbecidine @ (5 ml kg⁻¹), Karanj oil @ (5 ml kg⁻¹), Custard apple leaf powder @ (5g kg⁻¹), Castor oil @ (5ml kg⁻¹), Eucalyptus oil @ (5ml kg⁻¹), Gorakhmundi @ (5g kg⁻¹) and Deltamethrin 2.8 EC @ (0.04 ml kg⁻¹) seed were assessed for their effectiveness. Minimum per cent damage and weight loss were observed when the seed treated with Deltamethrin 2.8 EC @ 0.04 ml kg⁻¹ seed followed by Nimbecidine @ 5 ml kg⁻¹ and up to 6 months of storage under ambient condition. Germination percent was found significantly above the IMSCS level up to 6 months of storage when seed was treated with Deltamethrin 2.8 EC @ 0.04 ml kg⁻¹ seed

followed by Nimbecidine @ 5 ml kg⁻¹ seed. Percent seed moisture was depends on nature of seed protectants and storage environment. Seed vigour index was found significantly higher up to 6 months of storage when seed was treated with Deltamethrin 2.8 EC @ 0.04 ml kg⁻¹ followed by Nimbecidine @ 5 ml kg⁻¹. The residual effect Deltamethrin 2.8 EC @ 0.04 ml kg⁻¹ was found up to 6 month of storage. The present investigation advocated that seed protectants viz., Deltamethrin 2.8 EC @ 0.04 ml kg⁻¹, Nimbecidine @ 5 ml kg⁻¹ and Karanj oil @ 5 ml kg⁻¹ may be utilized as suitable seed protectants to maintain the seed quality above IMSCS level, for a long period of 6 months.

ORGANIC MATTER AS A CRITICAL COMPONENT IN SOIL HEALTH MANAGEMENT

RAZIA REHMAN¹, INAYAT MUSTAFA KHAN¹, ZAHOO RAHMAD BABA²

¹Division of Soil Science and Agricultural chemistry, ²Biofertiliser Research Laboratory, Faculty of Agriculture Wadura campus, Sopore, Sher-e-Kashmir University of Agricultural Science and Technology of Kashmir.

A healthy soil health is referred as the one that has the capacity to support the productivity of plants and animals, maintains air and water quality and health of all other living organisms it is harbouring. Soil organic matter though forming only 2-10 % of soil volume is beyond doubt very significant for maintenance of soil health in terms influencing its physical, chemical and biological properties. In coarse textured sandy soils, organic matter largely determines cation exchange capacity and can influence water holding capacity to a greater extent. In finer textured clay soils, soil organic matter is critical in maintaining soil structure and stability. Soils with optimum levels of organic carbon possess the capacity to resist the changes in pH due to the improved buffering capacity as a result of presence of hydroxyl groups on humic substances. Overall, adequate amounts of soil organic matter maintain soil quality, preserve sustainability of cropping systems and help to decrease environmental pollution by decreasing the toxicity of heavy metals to plants through absorption and also reducing the contamination of water ways and ground water by pesticides through adsorption. Formulating the fertilizer management strategies for the crops, the proper information about the organic matter levels in different soils is of paramount significance. A diverse types of biological processes mediated by microbes is essentially influenced by the presence or absence of organic matter content of soils. Since organic matter is a source of nutrients for soil microbes involved in release of carbon, nitrogen, phosphorus, potassium, sulphur and micronutrient from organic and mineral matter in soils, governs the population of these microbes. Researchers world over have reported that soils functions can be constrained when the organic carbon of a particular soil is less than one percent. The organic fraction of soil thus deserves utmost care with respect to its management for gifting the soil resource to the future generations in a better form.

INTEGRATED MANAGEMENT OF DISEASE IN BEANS

REENA VERMA

Botany Department, D.A.V College Dehradun

According to estimates made in India nearly 10-15% of food legumes production is lost due to diseases alone. Among fungi, diseases caused by species of Botrytis and Ascochyta are of great importance to faba bean. Then the lesion enlarged and became concentric. Mature leaves had coalescing necrosis surrounded by yellowing. Older leaves of the plant were particularly affected. In a later stage of the disease, the leaves became blighted from the margin to the center and most of the diseased plants defoliated. In severely infected fields, circular to irregularly shaped lesions also appeared on stems and pods, and plants defoliated completely. All tested isolates were pathogenic to broad bean leaves. Different isolates of the fungus varied in pathogenicity on different broad bean cultivars. In a comparison of symptoms of the disease and morphological characteristics of the isolated fungus with other broad bean diseases, this disease represented a new, as yet undescribed disease of broad bean in Japan. Faba bean (*Vicia faba*) plants showed symptoms of shoe stringed leaves, phyllody and flower abortion in experimental field. Therefore, we propose the name "leaf spot of broad bean". Disease on broad bean in different parts of Uttarakhand.

EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON FRUIT DROP OF KINNOW MANDARIN

REETIKA, G. S. RANA AND M. K. RANA

Department of Horticulture, CCS Haryana Agricultural University Hisar-125004, Haryana (India)

Citrus crops are relatively high nutrients demanding and highly responsive to applied nutrients in the form of fertilizers. Excessive fruit drop is a serious problem in Kinnow mandarin, which starts from blooming and continues till final harvest due to malnutrition. The experiment comprising of eleven fertilizer treatments in different combinations was conducted on seven years old earmarked plants at Experimental Orchard of the Department of Horticulture, CCS Haryana Agricultural University, Hisar during the year 2016-17 to study the effect of Urea, K₂SO₄, ZnSO₄, FeSO₄ and boric acid on fruit drop of Kinnow mandarin. The data were recorded on June drop and pre-harvest drop. The recorded data were subjected to statistical analysis using RBD. The results of present investigation indicate that the foliar application of Urea 1.0% + K₂SO₄ 1.0% + ZnSO₄ 0.5% + FeSO₄ 0.5% + H₃BO₃ 0.2% had a significantly positive influence and was quite effective in minimizing June and pre-harvest fruit drop in Kinnow mandarin. The decrease in fruit drop with the application of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

different nutrients in combination might be attributed to the fact that making up the deficiency of these nutrients in the plants, which are required for the synthesis of carbohydrates, which are essential for reducing fruit drop. The significant check on the economically important pre-harvest fruit drop by the combined foliar spray of these nutrients can be accredited to the activation of auxins which results in strengthening the fruit pedicels through their synergistic relationship between them by the retardation of abscission layer formation in pedicel at the point of attachment with fruit.

ORGANIC FOODS

RENU BALASHARMA

Organic food, food raised without chemicals and processed without additives. Organic food refers to crops or livestock that are grown on the farm without the application of synthetic fertilizers or pesticides, and without using genetically modified organisms. In contrast, the type of agriculture followed by most farmers, which does include the use of synthetic pesticides and fertilizers, is termed conventional agriculture. Organic foods are made according to certain production standards. IN 1939, Lord Northbourne coined the term organic farming. Food whose ingredients are at least 95% organic by weight may carry the USDA Organic Label products containing only organic ingredients are labeled 100% organic. Organic gardening uses organic seeds, organic, organic fertilizers, compost, organic root, stimulators and organic pest control.

QUALITY TEST OF MILK

RENU SHARMA¹ AND AMAN DEEPRANGA²

¹School of Bioengineering and Biosciences, ²Department of Genetics and Plant Breeding, School of Agriculture, Lovely Professional University, Phagwara-144411

Quality test is a set of test done to validate ample product quality in various standards. These efforts are done to enhance worth of dairy products and the reason behind performing these tests is that dairy products are very much susceptible to bacterial contamination. Tests are done for maintaining quality and food safety and thus provide technical guidance for milk analysis and testing their compositional, microbiological and adulterant content. Numerous tests are designed like Iodine test for glycogen and starch by using Lugol's iodine reagent, Molish's test for presence of carbohydrate by using reagent which is a mixture of naphthol in ethanol, Transparency test for observing oil content present in milk, Adulterant analysis of milk by finding the starch availability, detection of pulverized soap with the help of phenolphthalein indicator. Further tests include urea test, test for presence of boric acid and borates by using turmeric paper which is mixture of turmeric powder and ethanol, presence of detergent test, identification of synthetic milk test, turbidity test for checking efficiency of sterilization in milk that depends upon the denaturation of proteins and organoleptic test which comprises of all the preliminary quality tests such as sense of sight, smell and touch. In case of micro-organisms tests alkaline phosphatase is an indigenous milk enzyme. The enzyme activity is destroyed at pasteurization temperature and has been adopted as an index of the efficiency of pasteurization. All these tests are done to ensure whether milk is up to the accepted standards for chemical composition, purity and level of different micro-organisms.

Keywords: Adulterant, Denaturation, Pasteurization, Susceptible

LONG -TERM CONTINUOUS USE OF ORGANIC MANURES ON PRODUCTION POTENTIAL AND SUSTAINABILITY OF RICE BASED CROPPING SYSTEMS

RESHMA BORA

Rice is the staple food crop of India. About 90% of rice in the world is produced and consumed by the Asian countries. India has the largest area of 43.2 mha among rice growing countries and stands second in the production i.e, 110.15 mt with the productivity of 2050 kg/ha (Directorates of Economics and Statistics). There are popular rice based cropping systems in India such as rice-wheat, rice-rice-rice, rice-mustard, etc. There are several constraints in rice based cropping system as rice is a nutrient exhaustive crop; hence poor nutritional status and declining response of rice to nutrients are of much concern. In recent times, a plateauing in productivity of Rice-wheat cropping system appeared, possibly due to fatigued exploitation of natural resource base (Ladha et al., 2003). In many areas, yields started declining because of a decrease in factor productivity (Yadav 1998), and farmers have resorted to using higher than the recommended doses of mineral fertilizers to maintain previously attained yield levels. The application of nitrogen fertilizer either in excess or less than optimum rate affects both yield and quality of rice to remarkable extent, hence proper management of crop nutrition is of immense importance. (Meena et al., 2003). Since sustainability of the production system depends on the sustainable use of soil resources, it is necessary to develop and adopt soil management technologies that increase soil organic matter contents and biological activities and improve soil physical conditions to keep lands productive on the sustainable basis. Long term experiments provide the best possible means of studying changes in soil properties and processes and identifying emerging trends in nutrient imbalances and deficiencies to formulate future strategies for maintaining soil health by using organics in combination with inorganics. Bhatt (2017)

reported that treatment NPK+FYM managed to achieve highest soil organic matter (2.28 g/kg), available N, P and K (255.44 g/kg, 27.10 g/kg and 223.09 g/kg respectively) as compared to application of nitrogen alone over a period of ten years. Das et al., 2014, reported that Compost (30 kg N/ha) + Urea-N (90 kg/ha) found to have maximum yield (5.02 t/ha) as compared to the plots where Urea-N alone (120 kg N/ha) was applied.

Therefore, one of the most promising means for increasing yield in the rice-based cropping systems is to develop alternative nutrient management practices, which may increase factor productivity and crop yields. In this direction, application of organic manures can be a useful practice to increase crop yields along with soil fertility.

STUDIES ON COMPARATIVE EFFICACY OF INSECTICIDE AND ENTOMOPATHOGENIC FUNGI AGAINST TERMITE IN WHEAT CROP

RESHU SINGH¹, SHASHI MALA² AND RAJIV KUMAR SIROHI¹

¹Krishi Vigyan Kendra, Bulandshahr, ²Department of Zoology, IIMT College, Aligarh

Termites are social insects that live together as colony in a termitarium. They severely damage agricultural crops. Management of termites has largely relied on broad spectrum and persistent chlorinated organophosphate insecticides. Serious health hazards and environmental concerns due to extensive use of insecticides have led to the search for environmentally benign alternative methods of termite management. Among the diverse potential alternatives available for termite management, the use of entomopathogenic fungi is getting momentum. Entomopathogenic fungi, *Metarhizium anisopliae* and *Beauveria bassiana* are effective in the management of different species of termite. A field trial was conducted to evaluate efficacy of Chloropyriphos 20 EC @ 3.5 lit/ha (broadcasted with sand), *M. anisopliae* (@ 5 kg/ha FYM enriched) and *B. bassiana* (@ 5 kg/ha FYM enriched). *M. anisopliae* appeared to be most effective and caused 47.6% decrease in termite incidence and 15.5% increase in yield of wheat crop. In the Chloropyriphos 20 EC treated plot 41.5% decrease in termite incidence was recorded, which resulted into 12.6% increase in yield. Seed germination was significantly higher (91%) in micro plots treated with chloropyriphos 20 EC followed by *M. anisopliae* (89%) and *B. bassiana* (87%).

Key words: Termite, *B. bassiana*, *M. anisopliae*, chloropyriphos, germination.

CHEMICAL AND BIOLOGICAL CONTROL OF ROOT KNOT NEMATODE (*MELOIDOGYNE GRAMINICOLA*) IN PADDY CROP

RESHU SINGH¹, RASHMI NIGAM², RAJIV KUMAR SIROHI¹ AND SATISH KUMAR¹

¹Krishi Vigyan Kendra, Bulandshahr (U.P.), ²Department of Plant Pathology, Janta Vaidik College, Badot, Distt. Baghpat (U.P.)

The present field experiment was conducted to evaluate the efficacy of bio agents and chemical nematicides viz. *Trichoderma harzianum*, *Pseudomonas fluorescens*, *Bacillus subtilis*, Carbofuran 3G and Phorate 10G for management of rice root-knot nematode *Meloidogyne graminicola* during kharif-2014, 2015 and 2016. The present findings revealed that all the treatments were significantly superior over control with respect to plant growth parameters and nematode population. In control, terminal and spiral galls developed on rice roots, and plants suffered 32-41% decrease in the plant growth parameters and resulted upto 27% yield loss. At harvest greater decrease in soil population was recorded after soil application of *T. harzianum* (51.11%) followed by carbofuran 3G (46.82%). *T. harzianum* and carbofuran 3G were at par in suppression of root gall and egg mass suppression and *T. harzianum* caused 61.11 and 58.28% reduction in root gall and egg mass respectively, whereas, carbofuran 3G caused 59.52% and 62.50% reduction in root gall and egg mass respectively.

Key words: *M. graminicola*, rice, biological control, chemical control, plant growth

EMERGING TRENDS OF PROBIOTICS IN NON-DAIRY PRODUCTS

RIGZEN TSEWANG¹, KALURAM² AND MANOJ KUMAR²

¹Division of Post Harvest Technology, University of Horticultural Sciences, Bagalkot-587104, ²Division of Fruit Crops, ²Division of Vegetable Crops, ICAR- Indian Institute of Horticultural Research, Hessaraghatta lake post, Bengaluru-560089

There has been substantial development in the industry of probiotics as health drink. The increasing consumer awareness about the various health properties of probiotics has led to its great demand in recent years. They are considered as functional foods because of its nutraceutical properties. Probiotic foods or products are those which contain certain beneficial microorganisms in good amount ranges from 10⁶-10⁹ CFU/ml which mainly belongs to *Lactobacillus* and *Bifidobacterium* genera. They are mainly available as milk based probiotic health drinks in the market and has become successful in delivering the desired product. But there are certain factors which are to be considered before consuming milk based probiotic drinks. Milk based probiotic products have certain limitations such as more fat and cholesterol content. Certain sections of the population are more prone to dairy related allergies due to presence of certain proteins in it and also suffer from the condition like lactose intolerance. Whereas, fruit based probiotic products have none of these factors of consideration and have much more advantages compared to milk based one. Fruits are rich source of vitamins, minerals, along with good

taste, colour and are enjoyed by all age groups. So, along with added benefits of fruit based probiotic products it can add more value to the product and can be a successful venture. But one of the main challenges in the production of fruit based probiotic product is an altered taste and aroma of the product. Probiotic micro-organisms are known to produce different metabolic components such as acetic acid and lactic acid bacteria during fermentation and over the storage period. The quality of products containing probiotic mainly depends on the packaging materials used and the storage conditions under which the products are stored. But successful attempts have been made in recent years despite of such challenges and further research have to be done in exploring different fruits and vegetables crops along with potential and compatible probiotic micro-organisms.

EFFICACY OF NOVEL INSECTICIDES AGAINST CUTWORMS (LEPIDOPTERA: NOCTUIDAE) INFESTING CABBAGE

RIMPY* AND K S VERMA

Department of Entomology, Chaudhary Sarwan Kumar Himachal Pradesh Krishi Vishvavidyalaya, Palampur - 176 062, Himachal Pradesh, India.

Persistence toxicity of seven new insecticides viz; bifenthrin, chlorantraniliprole, cypermethrin, emamectin benzoate, flubendiamide, novaluron and spinosad was evaluated against third instar larvae of *Agrotis ipsilon* (Hufnagel) and *A. segetum* (Denis & Schiffermuller) under laboratory conditions. The result revealed that all the selected insecticides caused mortality of third instar larvae of both the species upto 15th day of spray except emamectin benzoate and cypermethrin where the mortality was recorded upto 10th and 7th day of spray, respectively. Flubendiamide 0.004% showed highest PT value of 1099.975 and 1125 against the third instar larvae of *A. ipsilon* and *A. segetum*, respectively.

CHARACTER ASSOCIATION STUDIES FOR QUANTITATIVE AND QUALITY TRAITS IN KNOLKHOL ((BRASSICA OLERACEA VAR. GONGYLOIDES L.) GENOTYPES UNDER SUBTROPICAL CONDITION OF JAMMU

RINCHAN DOLKAR*, R. K. SAMNOTRA, SANJEEV KUMAR AND ASHOK BUSTI

Sher-e-Kashmir University of Agricultural Sciences and Technology, Chatha, Jammu

Correlation and path coefficient analysis studies was carried out in thirty genotypes of knolkhol collected from various region of the states and some public sector varieties and hybrids at Vegetable Research Farm Sher-e-Kashmir University of Agricultural Sciences and Technology of Jammu during 2016-17 and the results revealed that the genotypic correlation coefficients were higher than phenotypic correlation coefficients for all the pairs of characters suggesting a strong inherent relationship between different traits. During the main season the marketable knob yield had positive and highly significant correlation with leaf length, number of leaves per plant, marketable knob diameter and gross weight per plant both at genotypic and phenotypic levels. Significant and negative correlation was observed for days to marketable maturity, beta carotene contents of leaves and calcium contents of knob and leaves and potassium contents of leaves. Path coefficient analysis for various traits showed that gross knob weight/plant had maximum positive direct effect on net knob weight/plant at genotypic level, followed by harvest index, petiole length and marketable knob diameter indicating that increase in marketable knob diameter, petiole length and gross knob weight/plant will improve the net knob weight/plant directly while maximum negative direct effect was recorded for calcium contents of leave followed by leave length, phosphorous contents of leaves, stalk length, leaf width and number of leaves/plant that while improving the net knob weight/plant. These observations suggested the selection of lower values for these traits.

Key Words : Character Association, Path analysis, Knolkhol, Quantitative traits.

“INFLUENCE OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH, YIELD AND QUALITY OF CABBAGE (BRASSICA OLERACEA VAR. CAPITATA)”

RISHABH DUBEY¹, MADAN JHA²

1. Department of Horticulture, Faculty Of Agricultural Sciences And Technology AKS University, Sherganj, Satna (M.P.), 2. Dept. of Vegetable science, BTC CARS, Bilaspur (C.G.)

The field experiment was conducted during Rabi season of 2017-18 at the Horticulture Research farm, AKS University, Satna (M.P.). The experiment was laid out in a randomized block design with three replications. The treatments consisted of nine combination of different agro input management practices viz., treatments 100 % RDF (Control) (T₁), 75 % RDF + 25 % N through VC (T₂), 75 % RDF + 25 % N through FYM (T₃), 50 % RDF + 50 % N through VC (T₄), 50 % RDF + 50 % N through FYM (T₅), 100 % RDF + 25 % N through VC (T₆), 100 % RDF + 25 % N through FYM (T₇), 100 % RDF + 25 % N through FYM + *Azotobacter* @ 2 kg ha⁻¹ + PSB @ 2 kg ha⁻¹ (T₈), 100 % RDF + 25 % N through VC + *Azotobacter* @ 2 kg ha⁻¹ + PSB @ 2 kg ha⁻¹ (T₉). The maximum net profit/ha was recorded under treatment T₉ (Rs. 182392.68) while minimum net profit/ha was obtained in treatment T₄ (Rs. 123469.25). The maximum gross profit/ha

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

was recorded in treatment T₉ (Rs. 230115.00) whereas, minimum gross profit/ha was recorded in treatment T₄ (Rs. 167260.00). Thus, the maximum income (both gross and net) was obtained with T₁₀. The significantly maximum B:C ratio 4.54 was recorded under the treatment (T₁). And the minimum B:C ratio 2.66 was recorded under the treatment (T₅).

BOTANICAL PESTICIDES: CONSEQUENTIAL COMPONENT OF INTEGRATED DISEASE MANAGEMENT **RISHIKADANGI AND SONAKSHI DAHIYA**

Department of Plant Pathology, CCS Haryana Agricultural University, Hisar-125004, India

The obtrusive and unfettered use of fungicide has resulted into different types of environmental haphazard, resistance of pest towards fungicides, pest resurgence and toxicological problems. Recently notion of exploitation of plant extract as chemo therapeutants for disease control are gaining popularity. There is growing demand for effective alternatives that present low health risk and conserve ecosystems and biological diversity. Plants are known to contain a number of secondary substances like phenols, flavanoids, quinines, essential oils, alkaloids, saponins, steroids etc. Some of these have anti-microbial properties and are toxic to phyto pathogens, insects and various pests. Use of plant based anti microbial substances provides an alternative method for sustainable agriculture by management of pathogens and pest along with reducing dependency on synthetic fungicides. Neem products such as neem oil are commercially available botanical pesticide. Now some essential oils from plants have also been reported to have antifungal properties. Plant materials, however, are often used inefficiently and their effective use requires optimization but if integrated in the disease management program have potential to be remunerative. Efficacy of botanicals alone or in combination with the fungicides is a sustainable strategy for the management of diseases. In context of agricultural disease management botanical pesticides are best suited and can play much greater role in the production and protection of crops. Plant extracts can prove to be remunerative if embedded into integrated disease management program.

Key words: Biopesticides, IDM, Anti microbial, Remunerative.

ROLE OF EPIGENETICS IN PLANT TISSUE CULTURE AND ITS FUTURE PROSPECTS

'RITU JAISWAL, DAYASHANKAR SINGH, 'SHASHIKANT BHARATI AND ²MUKESH KR. SINGH'

¹Dept. of Genetics and Plant Breeding, IAS, RGSC, BHU, Barkachha, Mirzapur-231001, ²Dept. of Genetics and Plant Breeding, Inst. of Agril. Sciences, RGSC, BHU, Barkachha, Mirzapur-231001

The term 'epigenetic' was originally coined by Waddington to describe the different mechanisms by which genes act together to control a phenotype, this term also has been co-opted by molecular biologists to describe the study of heritable information that is not fully explained by DNA sequence. In-vitro, epigenetic variation reflects that the adaptation process of cells to a different environment which includes the response to signals that may trigger switches in the developmental programme. Epigenetics is a very sensitive regulatory mechanism, which in most of the cases is affected by the environment. Epigenetic theories primarily emphasize the interaction between genes and the environment because the environment has a profound role in determining the epigenetic modifications occurring in an individual's genome that ultimately influence the organism's development and process of the heredity. Epigenetic changes in plant tissue culture are caused by changes in the expression of the information in the DNA brought about by covalent modifications occurring in the chromatin and allowing cells to sustain different traits in spite of containing the same genetic material. Due to interplay among epigenetic mechanisms such as DNA methylation, histone modifications, and micro RNA interference (RNAi). The chromatin structure is also critically affected. These modifications may influence gene transcriptions. If the chromatin is tightly packed (heterochromatin) due to DNA methylation, histone modifications and micro RNA interference (RNAi), the genes those are in the heterochromatin zones would not be available for the transcription machinery. In consequence, the particular gene or genes will be silenced or their expression is markedly decreased. Regulation of these mechanisms influences gene expression by modifying the access to the underlying genetic information, ultimately affecting phenotypes. This is another area of emerging science which helps us in future with several ways to genetic improvement of the plants and animals or living beings.

VALUE ADDITION IN FLORICULTURE (ESSENTIAL OILS)

RITU YADAV

Department of horticulture (FLA), CCS Haryana Agricultural University, Hisar-125004, India

Value addition is to increase the profit value and consumer attraction of a commodity. There are different ways to add value to your goods like by process the raw material, pre-cut wrap and package, take a unique approach, label your product, distinct product appearance, increase shelf life, provide recipes/cookbook, gift baskets or multi-pack, build reputation, relationship. Essential oils, also known as vegetable oils, are complex mixtures of organic substances and are terpene derivatives, phenylpropanoid various hydrocarbons and

straight chain compounds. They are chemically active and take part in metabolic reaction. Essential oils act as attractants for certain pollinating insects or feeding animals against plant parasites, hostile insects, attack by microbes or depredation by browsing animals. Besides, they help in developing allelopathic strategies by preventing the germination and growth of other plants vicinity and even cause the death of encroaching plants in some cases. The application of essential oils are indigenous marketing, export, perfumery, cosmetics, essences, fragrant commodities, medicines. Different essential oil crops are rose, jasmine, tuberose, narcissus, murraya, marigold, calendula etc. Essential oils are known to occur in every organ of the plant, for example, flowers (rose, jasmine, cananga, tuberose), leaves (mint, sage, rosemary), bark (cinnamon), rhizomes (ginger), wood (cedar, sandal wood) etc. the amount of essential oils varies from an infinitely small quantity to as much as 1-2 % (upto 18 % in cloves). There are five methods of extracting essential oils from plants: distillation, enfleurage, maceration, solvent extraction, mechanical expression and adsorption depending upon the nature of plant material, the amount of oil present and the relative stability of various compounds.

Key word: Essential oils, Perfumery, Value addition, Distillation.

DIVERSITY OF INSECT FAUNA IN HORTICULTURAL CROPS OF ASSAM AGRICULTURAL UNIVERSITY, CAMPUS, JORHAT, ASSAM

Ritushree Mahanta, Shabrin S Ahmed, Anjumoni Deves, Department of Entomology, Assam Agricultural University Jorhat, Assam

A study was conducted to know the status of abundance of various insect species under different orders in banana, citrus, brinjal, tomato, cabbage and okra crops present in experimental garden, Department of Horticulture, Assam Agricultural University, Jorhat, Assam. Insects were collected by sweeping nets and hand picking from January 2016 to November 2016. Altogether 85 species of insects belonging to 8 orders and 34 families have been recorded. Per cent relative species abundance for different orders were 31.76% (Lepidoptera), 38.82% (Coleoptera), 10.58% (Hymenoptera), 14.11 % (Hemiptera), 7.05% (Orthoptera), 5.8% (Odonata), 3.5% (Diptera), 1.1% (Neuroptera). Among the orders, Coleoptera was the dominant one followed by Lepidoptera, Hemiptera and the lowest abundant one was Neuroptera. Among the families, Coccinellidae was the dominant one with six species and lowest one was Chrysopidae with one species i.e. *Chrysoperla carnea*. Among the crops highest number of insect species were found in Brinjal (12 species) followed by cabbage and okra (11 species) and lowest was found in Banana (3 species). In this experiment, diversity indices i.e. species richness, species evenness and species diversity were also calculated. The seasonal abundance of different species was also studied. In case of banana and citrus, insect abundance was highest in the month of July-August. In case of cabbage, tomato and brinjal abundance was highest in March and in okra it was May-June. Key words: Relative species abundance, seasonal abundance, diversity indices

SOIL CONDITIONER - A CONTRIVANCE FOR IMPROVING SOIL QUALITY

ROHEELA AHMAD, RAJNISH YADAV, GULZARA AHMAD BHAT, HAZIQ SHABIR, ASHA QA AHMAD

Division of Soil Science and Agricultural Chemistry, SKUAST, Kashmir

A soil conditioner is a product which is added to soil to improve the soil's physical qualities, usually its fertility (ability to provide nutrition for plants) and sometimes its mechanics. In general usage, the term "soil conditioner" is often thought of as a subset of the category soil amendments, which more often is understood to include a wide range of fertilizers and non-organic materials. Soil conditioners can be used to improve poor soils, or to rebuild soils which have been damaged by improper soil management. They can make poor soils more usable, and can be used to maintain soils in peak condition. Soil quality is the capacity of a specific kind of soil to function within ecosystem and land use boundaries, to sustain biological productivity, maintain environmental quality, and sustain plant, animal and human health. Soil conditioner improves the physical, chemical and biological quality of soil. It includes Minerals (e.g. gypsum, lime, etc.), Modified rocks and minerals (e.g. sand, clay, rockwool, pumice, etc.), Industrial by-products (e.g. steel mill slag, press mud), Organics (e.g. compost, sea weeds, humates, etc.), Microbes (e.g. Blue green algae- *Anabaena*, *Spirulina*, etc.) and Synthetic Polymers (e.g. polyacrylamide, poly vinyl alcohol, Hydrogels, etc). Soil conditioners optimize one or more soil physical properties, such as bulk density, porosity, aggregate stability, dispersivity parameter, erodibility, rain splash detachment, soil crusting, hydraulic conductivity, water retention characteristics, plant-available water capacity, air capacity, infiltration rate and cumulative evaporation. Many of the soil conditioners increase total microbial counts of sandy and calcareous soils. Application of Cyanobacteria as soil conditioner in salt affected soil resulted in significant improvement in the aggregation status of soil by producing exo-polysaccharides and brought down appreciably the pH, electric conductivity and exchangeable sodium, furthermore they increased considerably the hydraulic conductivity of soil. In this era of intensive agriculture where our soil and environment are under threat of degradation, soil conditioners are helpful to improve its quality.

Key words- Soil conditioner, Soil Quality, Soil properties

RESPONSE OF RICE TO EFFICIENT NITROGEN MANAGEMENT UNDER IRRIGATED CONDITIONS**ROHIT KUMAR¹, ADESH SINGH¹, R.B. YADAV¹ AND ATIN KUMAR²**¹Department of Agronomy, ²Department of Soil Science, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut, Uttar Pradesh-(250 110), India

A field experiment was conducted during *kharif* season of 2015 at Crop Research Centre (Chirauri), Meerut (U.P.) on the effect of efficient nitrogen management in rice. The soil of the experimental field was well drained, sandy loam in texture and slightly alkaline in reaction. It was medium in organic carbon, available phosphorus and available potassium but low in available nitrogen with an electrical conductivity (1:2, soil: water) of 1.65 dS/m. Ten treatments comprised of splitting of nitrogen as basal, at tillering, panicle initiation and milking stage in different proportions including foliar spray, use of LCC (<4) and control were tested in a randomized block design with 3 replications. The results indicated that the growth and development parameters (plant height, tiller/m², leaf area and index, dry matter accumulation, CGR, RGR, and NAR), yields (grain, straw and biological) per ha and uptake of nitrogen in rice were significantly superior with the application of 1/4 as basal + 1/4 at tillering + 1/4 at panicle initiation and 1/4 at milking stage (T₃) as compared to rest of the treatments, except T₂ (1/2 N as basal, 1/4 at tillering, 1/4 at panicle initiation and 1/4 at milking stage) and T₁₀ (1/4 N as basal, rest through leaf colour chart). However, T₃ treatment gave 60 and 32 kg/ha higher grain and straw yields as compared to T₂ (existing recommendation of N), respectively. However, the highest crop growth rate and photosynthetic rate was between 30 to 60 days in T₃ treatment. The rice also accumulated significantly higher nitrogen in grains, straw as well as total (75.98, 49.15 kg/ha and 125 kg/ha, respectively) in T₃ as compared to all the treatments, except T₂ and T₁₀. Besides, partial factor productivity, agronomic and recovery efficiency in T₃ was improved by 1.43, 2.41 and 3.69 per cent, respectively as compared to T₂ (existing recommended N schedule). The split application of nitrogen as 1/4 basal, 1/4 at tillering, 1/4 at panicle initiation and 1/4 at milking stage (T₃) brought Rs 97569, 64189/ha and 1.78 as gross, net returns and B:C ratio, respectively, being highest among all the treatments followed by application of nitrogen in three equal splits (T₂).

Keyword: Response, accumulation, photosynthetic, development, nitrogen and rice**EFFECT OF SMART TECHNOLOGY ON HONEYBEE COMMUNICATION****ROHIT KUMAR NAYAK¹, PARAM VEER SINGH² AND SHITAL YADAV³**^{1,2}Department of Entomology, ¹SKN Agriculture University, Jobner, Jaipur (Raj)-303329, ²Dr. Y S Parmar University of Horticulture & Forestry, Nauni, Solan (H.P.) 173230, ³Department of Soil Science, ³SKAU, Bikaner (Raj) - 334006

Honeybees are social insects; this is due to they live in the colonies and each caste have a special work in the colony. Good communication is necessary for a successful survival of colonies. During last few years, honey bees are disappearing in the world. Many reasons are responsible for this environment disaster like climate changes, pesticides and bacterial- fungal pathogen. But in recent years, smart technology becomes an emerging factor that affects the communication of honey bees. Bees use cryptochrome for navigation. They follow it to sense the direction of the earth's magnetic field and sources of food. Microwaves and radiations generated through various wireless smart technologies affects the specific sense organs, enabling them to navigate using their own compass. So bees do not find their way back to the hive. These technologies also disturbing the life cycle, reproduction system and honey production.

Keywords: Smart technology, honeybee communication, cryptochrome, radiations, sense organs**SOIL AND WATER CONSERVATION FOR SUSTAINABLE AGRICULTURE****ROHIT KUMAR SINGH¹, VED PRAKASH², AMIT KUMAR SHUKLA³, THOTA DIVYASREE⁴, ANANDITA SUPRIYA⁵**¹Department of Agronomy, University of Lucknow, Lucknow, U. P. (India), ²Department of Agronomy, BAU, Sabour-813210, Bhagalpur, Bihar (India), ³Department of Crop Physiology, NDUAT, Kumarganj, Faizabad-224 229, U. P. (India) ⁴AIMT, Dehradun, Uttarakhand, (India), ⁵ITM University, Gwalior, M.P. (India)

Soil and water are the most valuable natural resources and an important to human being. The natural resources of the State involve land, water, soil and biodiversity, which dictate the opportunities for livelihoods and income for the peoples. Both are facing threats of decay due to unrelenting human pressure and utilization incompatible with its capacity. Soil profile play role as storage for all water. Degradation and unscientific cultivation practices result in decrease of top fertile soil. This cause to depletion of nutrients in fertile soil, resulting in low yield, unviable agriculture, sedimentation in reservoirs leading to reduction in storage capacity, decrease cultivable area and finally influences the cycle of power generation, ecological imbalance, environmental pollution, drought and floods. Conservation tillage technique include less soil disturbance, permanent soil cover through crop residues or cover crops, and crop rotations for achieving higher productivity. Water loss occur through mainly Evaporation and Transpiration. Other factors like Solar radiation, wind speed, available soil moisture, depth of root, types of soil and season also reduce the moisture availability in soil. For conserving the soil and water to use the organic manures, green manure crops and also reduce tillage operations. For conserving soil use contour farming,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

direction of tillage, use minimum tillage or zero tillage also use windbreaks and shelterbelts. Practices to conserve both soil and water is covering the soil with cover crops, planting pattern, use conservation tillage practices, grow deep rooted crops and crop residues cover etc.

Key worlds: Biodiversity, Conservation, Environment, Natural resources, Tillage

IMPORTANCE OF PRUNNING IN HORTICULTURE CROPS

ROHIT KUMAR¹, BINDHYA PRASAD², AMIT KUMAR MISHRA³

Ph.D. (Research Scholar) Department of Horticulture, Bhagwant University Ajmer, Rajasthan, 2- Assistant Professor, Department of Horticulture, Bhagwant University Ajmer Rajasthan, 3- Assistant Professor, Department of Agriculture, Bhagwant University, Ajmer, Rajasthan

Pruning is the practice of removing specific portions of a tree or shrub (such as root, buds, branches, stem) that are dead due to pests, disease and lack of sunlight and aesthetic purpose. In pruning the removal or reduction of parts of a plant, tree, is common practice in orchard and vineyard management for the improvement of flowering and fruiting. It is started in later part of plant life, when it becomes capable to produce flower and fruits on tree and shrubs will often grow to size that exceed the space which is limited. Regularity of this method is necessary on a formal plant and hedge to maintain a plant for health reason. Pruning includes many methods viz. - Heading back, Thinning, Ringing or Girdling, Notching, Nicking.

MATURITY INDICES, HARVESTING AND POST HARVEST HANDLING OF FRUITS AND VEGETABLES

ROHIT MAURYA¹, ABHINAV KUMAR², MANJEET KUMAR¹, SHRAVAN KUMAR¹ AND NISHAKANT MAURYA¹

Department of Vegetable Science¹, Department of Horticulture², Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad

Maturity is the stage of fully development of tissue of fruit and vegetables only after which it will ripen normally. During the process of maturation the fruit receives a regular supply of food material from the plant. When mature, the abscission or corky layer which forms at the stem end stops this inflow. Afterwards, the fruit depend on its own reserves, carbohydrates are dehydrated and sugars accumulate until the sugar acid ratio form. In addition to this, typical flavour and characteristic colour also develop. It has been determined that the stage of maturity at the time of picking influence the storage life and quality of fruit, when picked immature like mango develop white patches or air pockets during ripening and lacking in normal brix acid ratio or sugar acid ratio, taste and flavour on the other hand if the fruits are harvested over mature or full ripe they are easy susceptible to microbial and physiological spoilage and their storage life is considerably reduce. Such fruits persist numerous problems during handling, storage and transportation. Therefore, it is necessary or essential to pick up the fruits or vegetables at correct stage of maturity to facilitate proper ripening, distant transportation and maximum storage life.

Keywords - development of tissue, characteristic, maturation etc.

EFFECT OF WHEAT INTERCROPPING WITH CHICKPEA AND MUSTARD ON YIELD ATTRIBUTES

ROHIT THAKUR¹* AND GEETA KANDPAL¹

**Department of Agronomy, School of Agriculture, Lovely Professional University, Phagwara, 144411 Punjab, India, 1Assistant Professor, Department of Agronomy, Lovely Professional University, Phagwara, 144411 Punjab, India*

Wheat is one of the most important cereals around the world and most suitable for intercropping. Intercropping is an advanced agronomic technique that allows two or more crops to yield from the same area of land. On the basis of above statement, the effect of different intercropping of wheat with chick pea and mustard in different row proportion provide the qualitative biological yield. An experiment is started in the experimental field of Lovely Professional University based on completely randomized design with three replications. The three treatments are arranged in different row proportion i.e. (1:1,3:2,4:1). In this experiment we focused on different physiological, biological attributes, effect of different row proportion on yield and weed Index. The combination system of wheat with chickpea and mustard decrease the disease infestation and attributed higher production. On the behalf of research trial we conclude that intercropping may significantly enhance the crop productivity. Further research needs to consecutively understand about the intercropping interaction with soil and plant.

Keywords: Chickpea, intercropping, mustard, wheat, yield

NANO-FERTILIZERS FOR HIGHER NUTRIENT USE EFFICIENCY AND ENVIRONMENTAL SUSTAINABILITY

ROMAN NISSAR^{1*}, ASHAQ HUSSAIN², MANZOORA. GANAI², RAHEEL SHAFEEQ KHAN³, SAMIA MOONA⁴

¹ Division of Agronomy, FOA, SKUAST-Kashmir, Wadura, ² MRCFC, SKUAST-Kashmir, Khudwani, ³ Division of Genetics and Plant

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Breeding, FOA, SKUAST-Kashmir, Wadura, ⁴FVSc & AH, SKUAST-Kashmir, Shuhama

Nanotechnology, emerging as an escalating technology, seeks nano-scale or nano-structured materials which act as vectors or carriers for the controlled release of fertilizers and hence gives way to "smart fertilizers" which not only amplifies the nutrient use efficiency but also curtails the cost of environmental pollution. Nano-fertilizer, a product in nanometer regime and having particle size of less than 100 nm, is aimed to deliver nutrients to crops. They emerge as a precise nutrient management tool by providing nutrients all through the crop growth period in synchronization with the nutrient requirement during a particular crop growth stage. Chemical fertilizers do not present a suitable option for increasing the crop productivity for feeding the ever growing population due to its pernicious consequences on the soil health and biodiversity. Accordingly, nano fertilizers come to our rescue by supplying nutrients in a controlled manner in accordance with the crop demand. It is estimated that about 40-70% of nitrogen, 80 -90% of phosphorus, and 50-70% of potassium of the applied fertilizer is lost to the environment. Nano-fertilizers reduce the rate of dissolution of the fertilizer by slow, sustained release of coated fertilizer, resulting in efficient absorption of these fertilizers by the plant roots. Iron nanoparticles increases the number of pods/ plant (47%), weight of 1000 seeds (7%), chlorophyll (10%). Silver nanoparticles enhance seed germination (76.11%), root length (76.94mm) at 10ug/ml. Zinc oxide nanoparticles increase zinc dissolution and its bioavailability in soils with calcium carbonate. In the field of research considering higher nutrient use efficiency and environmental sustainability nano-fertilizer is emerging as an important core subject, thereby large scale production of physiologically important metals should be thrust. Nanoparticles come with high surface area, sorption capacity, and controlled release kinetics which makes them "smart delivery system", releasing their active ingredients only in response to environmental triggers and biological demands. Thus, nano-fertilizer has become a paramount alternative for evolution of environment friendly and sustainable agriculture.

Keywords: environmental sustainability, nano-fertilizers, nanoparticles, nutrient use efficiency, smart fertilizers, sustained release.

SCREENING OF COTTON GENOTYPES AGAINST WHITEFLY (*BEMISIA TABACI*)

ROOMI RAWAL, YOGESH KUMAR, KK DAHIYA, SHIVANI KHOKHAR AND ADESH KUMAR¹

Department of Entomology, CCS Haryana Agricultural University, Hisar, ¹KVK, Jhansi

Cotton crop has a global significance as it is commercially cultivated on large scale for fibre purpose and also known as "White gold". Cotton is infested by a number of sucking insects including the whitefly, *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae), which is one of the most notorious pests in tropical and subtropical agriculture. Both nymphs and adults cause direct damage by piercing and sucking of sap from the foliage of plants. *B. tabaci* is considered the most common and important vector of cotton leaf curl virus that spread the cotton leaf curl disease. To control this pest a large no of insecticidal spray are used. But continuous and indiscriminate application of these insecticides had resulted in development of resistance in whitefly to these insecticides. So the best option is to development of genotypes which can resist the attack of this pest. Current experiment was conducted at cotton section, Department of Genetics and Plant Breeding, CCSHAU, Hisar during 2017. Ten cotton genotypes (CSH3088, CSH3129, CSH3158, PUSA5760, SUFLUM, PBH47, CNH108, ARBH1601, HS294, F 2501) were screened against whitefly. Pusa 5760 genotype showed minimum population of whitefly (8 adults/leaf) amongst all genotypes. It was followed by PBH 47 (9.25 adults/leaf), SUFLUM (10.21 adults/leaf) and CSH 3158 (11 adults/leaf). Maximum population of whitefly was recorded on HS294 (18.25 adults/leaf) followed by CNH-108 (17.75 adults/leaf) and CNH 3129 (17.25 adults/leaf).

POPULATION DYNAMICS OF SPOTTED BOLLWORMS ON COTTON GENOTYPES AND THEIR CORRELATION WITH ENVIRONMENTAL FACTORS

ROOMI RAWAL, KK DAHIYA AND ADESH KUMAR¹

Department of Entomology, CCS Haryana Agricultural University, Hisar, ¹KVK, Jhansi

Cotton is a major fibre crop, called white gold. Spotted bollworm is an important pest of cotton causing damage to fruiting bodies and shedding of squares, flowers and bolls. This pest not only reduces the yield but also adversely affect the quality of lint and seed. Their damage differs in *Bt* and non-*Bt* cotton genotypes. Therefore the current study was done to evaluate reaction of seven cotton genotypes comprising of five *Bt* hybrids, one conventional hybrid and one variety for resistance against spotted bollworm at Cotton Section, Department of Genetics and Plant Breeding, Chaudhary Charan Singh Haryana Agricultural University, Hisar under unsprayed condition. Sowing was done on May, 2014 using standard package of practices with randomized block design (RBD). To record the larval population of spotted bollworm, five plants from each treatment per replication were physically searched. For this all the available green bolls were taken in to account as these bollworms are basically found to feed on these plant parts. Pest population was recorded at weekly intervals. It was started from 30th SMW and continued till harvesting of crop. It was found that incidence of bollworm started from 33rd standard meteorological week and continued till 41st SMW. Bollworm larval population reached to its peak during 40th SMW with larval population (1.36 larvae/plant). Larval population showed significant and negative correlation with minimum temperature and sunshine hours.

INTEGRATED FARMING SYSTEM AN ECOFRIENDLY APPROACH FOR SUSTAINABLE AGRICULTURE ENVIRONMENT

ROSAN KUMAWAT

Agriculture university, Kota, Rajasthan

Sustainable development in agriculture must include integrated farming system (IFS) with efficient soil, water crop and pest management practices, which are environmentally friendly and cost effective. In IFS, the waste of one enterprise becomes the input of another for making better use of resources. In integrated crop livestock farming system, crop residues can be used for animal feed, While manure from livestock can enhance agricultural productivity. IFS also play an important role in improving the soil health by increasing the nitrogen, phosphorous, organic carbon and microbial count of soil and thus, reduces the use of chemical fertilizers. Moreover, IFS component are known to control the weed and regarded as an important element of IPM and thus minimize the use of weed killers as well as pesticide and thus protects the environment. The water use efficiency and water quality of IFS was better than conventional systems.

STUDIES OF INTEGRATED NUTRIENT MANAGEMENT ON SUGAR BEET (*BETA VULGARIS* L.) CV. DETROIT DARK RED.

ROSHAN KUSHWAH, NIKHIL JHARIYA, MANEVENDRA SINGH SOLANKI AND DALVEER SINGH

Department of Horticulture R.B. S. College, Bichpuri, Agra

The Sugar beet (*Beta vulgaris*) belongs to the family *Chenopodeaceae* which is a herbaceous biennial and winter vegetable crop. It is native to central and southern Europe and has now spread all over the world. It is a newly introduced modified root crop in our country. Sugar beet has considerable nutritive value compared to other Cole crops that we commonly use in our daily diet. The fleshy root and young leaves are the main edible portion. Keeping these importance's the present study was under taken at the Department of Horticulture Raja Balwant Singh College, Bichpuri, Agra during 2016 - 2017. The experimental variety D.D.R. was sowing at the distance of 40 X 10 cm. The trails have 8 treatment combinations viz. T1(80%RDF+FYM), T2(80%RDF+FYM+ Vermicompost), T3(,60%RDF+FYM),T4(60%RDF+FYM+Vermicompost),T5(50%RDF FYM),T6(50%RDF+FYM+Vermicompost),T7(Full dose of RDF)and T8(Control No organic, NO fertilizer). The experiment was conducted under Randomized Block Design which was replicated three times. On the basis of data recorded during experimentation it was found that significant effect among treatment and maximum inhance in plant height (18.03 cm), total no. of leaf per plant (10.66), the number of fully opened leaves per plant (09), length of the largest leaves (21.4cm), width of the largest leaf (9.86cm) and fresh weight of leaf per plant (9.66) at harvest. Besides, the fresh weight of root(343gm), length of the whole root (7.33cm), diameter of storage root the shoulder point(7.42cm) and total root yield 355.9 Q/ha. Were recorded under T2 80%RDF+FYM+Vermicompost) followed by T4 (60%RDF+FYM+Vermicompost).

PESTICIDES: ITS DETRIMENTAL EFFECT ON EARTHWORMS AND SUSTAINABLE AGRICULTURE

ROSHNI RITU MURMU AND D. K. BOSE

Department of Agricultural Extension and Communication, Sam Higginbottom University of Agriculture, Technology and Sciences, Allahabad (U.P) -211007, India

The natural resources are finite and highly prone to degradation by the misuse of land and mismanagement of soil. The world is in great need of a healthy ecosystem that provides with fertile soil, clean water, food and other natural resources. Anthropogenic activities like intensification of industrial and agricultural practices, chiefly the use of pesticides have lead to increased contamination of land. Earthworms are considered as important bio-indicators of chemical toxicity. Also they help in a number of tasks that support many services that favour agro-system sustainability but are degraded by exhaustive practices like use of pesticides. They are impacted by pesticides at all organizational levels, for example ;pesticides disrupt their enzymatic activities, increase individual mortality, decrease functionality and growth, change individual behaviour such as feeding habit and decrease the overall community biomass density. Some pesticides have drastic effect on the nervous system of the Earthworm. Earthworms can accumulate heavy metals from soil in higher levels than any other animals. Therefore, we strictly need to rethink on the policies and norms devised by us on sustainable ecology. The natural resources should be utilized in an equivalent way and further essential ways for betterment of present and future livelihood should be sought.

Keywords: Natural resource, Mismanagement, Pesticides, Earthworms, Organizational levels, Heavy metals.

EFFECT OF GA₃ PRIMED SEEDS ON YIELD AND QUALITY OF SOYBEAN (*GLYCINE MAX* L.) UNDER VARYING SEED RATE AND SOWING METHODS**¹RUPINDER KAUR JASSAL* AND ¹HARMEET SINGH**¹Dept. of Agronomy, Punjab Agricultural University, Ludhiana (141004), Punjab, India

The influence of seed priming on yield and quality of 'SL 958' soybean was studied during 2015 and 2016. Experiment comprise of two sowing methods namely bed planting (67.5 cm wide, 2 rows per bed) and flat sowing (45 cm spacing) and three seeding rates i.e. 50, 62.5 and 75 kg ha⁻¹ in soybean [*Glycine max* (L.) Merrill]. The results showed that bed planted method recorded 15.6 % increase in seed yield than flat planting method. This enhancement in yield is due to significantly more number of pods per plant (25.8 and 26.1) and comparative more seeds per pod and 100 seed weight. With respect to seed priming treatments, primed seeds recorded significantly maximum seed yield i.e. 2278 kg ha⁻¹ as compared to non-primed seeds i.e. 1849 kg ha⁻¹ which was 23.2 % more as compared to non primed seeds. Significantly maximum seed yield was recorded when 62.5 kg ha⁻¹ (2177 kg ha⁻¹) seed rate was used as compared to 50 (1934 kg ha⁻¹) and 75 kg ha⁻¹ (2081 kg ha⁻¹). Seed rate of 62.5 kg ha⁻¹ recorded increase of 4.61 % in seed yield than 75 kg ha⁻¹ and 12.6 % with 50 kg ha⁻¹ seed rate. Similarly, the quality parameters of soybean like protein content, starch content and oil percentage recorded better results with primed seeds at the seed rate of 62.5 kg ha⁻¹ under bed planting method.

Keywords: soybean, seed priming, planting methods, seed rate, yield**ADVANCE TOOLS AND TECHNIQUES FOR EFFICIENT RESOURCE MANAGEMENT IN DRYLAND AGRICULTURE
RUXANABI NARAGUND, Y.V. SINGH, PRAVEEN KADAM AND HIMANSU SEKHAR GOUDA***Division of Agronomy, ICAR-Indian Agricultural Research Institute, New Delhi-110012*

India has 78 million hectare (mha) of drylands that account for 64% of the total net sown area (NRAA, 2018). Nearly 40% of the human population and 60% livestock depend on rainfed agriculture. Rainfed agriculture in India contribute ~42% of the total food grain production, 75% oilseeds, 90% pulses and ~70% of cotton. In the past, greater attention had been given towards the development of irrigated areas and rainfed areas were either ignored or given inadequate importance due to intrinsic risks involved investment on the development of rainfed/ drylands. With the productivity of irrigated crops reaching a plateau due to declining factor productivity, rainfed agriculture still offers scope for enhancing productivity. By the end of the 21st century, the contribution of drylands will have to be 60% if India is to provide adequate food to its over 1 billion people. Hence, tremendous efforts both in the development and research fronts are essential to achieve this target. In order to achieve these goals and to overcome the problems (less moisture, soil erosion and low soil fertility, etc.) in dryland agriculture, there is need for efficient resource management with advance tools and techniques. Agriculture practicers must harness the advances in modern science tools and techniques like remote sensing, geographical information system, global positioning system, conservation agriculture, plastic mulching, solar powered micro-irrigation, laser land levelling, aqua-sowing, hydrogels/ polymers and site-specific nutrient management to improve productivity and profitability, and resource-use efficiency of the dry land areas. Conservation agriculture, one of the most emphasized production systems, is an approach to managing agro-ecosystems for improved and sustained productivity, increased profits and food security while preserving and enhancing the resource base and the environment. Among the nutrient management options, Nutrient Expert® based site specific nutrient management (SSNM) had a much larger effects on crop productivity, water-use and incident radiation conversion efficiency compared to other practices. Aqua-sowing-cum-fertilization increase the supply of nutrients and water to the growing seedlings, thus helps in better establishment and gives early boost to the plants and ultimately increase the productivity. Therefore, adoption of available tools and technologies is necessary for increasing the productivity of dryland regions for ensuring food and nutritional security of ever multiplying population vis-à-vis sustainability of natural resources.

**GENETIC DIVERSITY STUDIES IN WHEAT (*TRITICUM AESTIVUM* L.) FOR GRAIN YIELD AND RELATED TRAITS.
KAMLESH KUMAR, S.C. GAUR, L.B. GAUR, AND A.K. GAUR***Department of Genetics and plant Breeding Baba Raghav Das Post Graduate college, Deoria (U.P.) 274001*

Wheat is the second major food crop of the world in importance next to rice. The field experiment under present investigation was conducted during rabi 2017-18 at Agricultural Research Farm of B.R.D.P.G. College, Deoria (U.P). The experiment was conducted to evaluate 81 wheat germplasm line in normal soil under timely sown and irrigated condition with Augmented Block Design. 81 wheat genotypes were investigated to understand the extent of genetic diversity through 14 quantitative traits Mahalanobis's D² analysis established the presence of wide genetic diversity among these genotypes by the formation of 10 different non-overlapping clusters. Cluster 10 had the maximum number of genotypes i.e. 17 and cluster 4 had only one genotype. Maximum intra cluster distance was observed in cluster 4 indicated that genotypes are having diverse genetic architecture. The cluster value between cluster IV (2850.68), cluster VII (2617.85) cluster III (2417.44) and cluster II (2336.23) were also very high. The minimum inter cluster D² value (393.406) was recorded. In case of cluster IV (2850.60) higher inter cluster distance indicated greater genetic diverse between the genotypes of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

those cluster while lower inter cluster values between the clusters suggested that the genotypes of the clusters were not much genetically diverse from each other. On the bases of inter cluster distances and *per se* performance observed in the present study a hybridization programme involving genotypes for specific characters can be selected using cluster mean values.

RELATIONSHIP BETWEEN CONCENTRATION AND EXPOSURE PERIOD IN THE TOXICITY OF PHOSPHINE TO *TROGODERMA GRANARIUM* EVERTS

S. K. YADAV* AND C. SRIVASTAVA

Division of Entomology, ICAR-Indian Agricultural Research Institute, New Delhi-110012, India

The experiments were conducted to determine the effects of phosphine concentration and exposure period on susceptible and resistant strains of *Trogoderma granarium* by the equation $C^*t = k$. *T. granarium* is one of the major insect pests of stored products causing considerable loss in India. Fourth instar larvae were exposed to a range of concentrations for fixed exposure periods of 6, 12, 24, 48, 72 and 96 h for the susceptible strain and 12, 24, 48, 72, 96, 120 and 144 h for resistant strains, and to a range of exposure periods for fixed concentrations range from 0.01 to 4.5 mg/l for susceptible strain and 0.10 to 9.0 mg/l for resistant strain at 35°C. C^*t relationships of the form $C^*t = k$ showed that the toxicity index, n was less than one in all cases indicating that time was more important variable in the toxicity of phosphine in these ranges of exposure periods and concentrations for both susceptible and resistant strains.

Key words: probit analysis, aluminium phosphide, fumigation, resistance, mortality

EVALUATION OF ENRICHED VERMICOMPOST ON GROWTH AND YIELD OF CHICKPEA (*CICERARIETINUM* L.)

S.B.AGRAWAL, RUCHI GUPTA, ATUL SHRIVASTAVA AND V.B.UPADHYAY

Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (MP)-482004 India

Managing soil health is an important aspect of sustainable crop production. The physical, chemical and biological processes govern the productivity. Soil organic matters integrate these three important processes. Apart from the integration of organic matter provides nutrition for the organisms exist with the soil. On the other hand, production of nitrogenous fertilizers emit out certain harmful GHGs. The total GHGs emission from production and application of fertilizers ranging from 1.5 to 16.7 kg. Co₂ eq per kg. fertilizer N. Therefore escalating the fertilizer use efficiency and curtailing the input dependency, are the primary way to reduce the cost of input and optimize the productivity. In this regard, recycling of degradable bio-waste through the action of flora and fauna is the key technology for production and use of quality vermicompost. A field experiment was carried out with thirteen treatments consisted of vermicompost prepared from soyabean straw and paddy stover as well as these were inoculated with Trichoderma + PSB, Trichoderma + cow dung, Trichoderma + PSB + cow dung, RP+PSB, RP+PSB+Trichoderma compared with un-inoculated vermicompost and RDF (20:60:20 kg NPK/ha) for plant population, pods/plants, seeds/pod, grain yield/plant as well as grain and straw yield/ha. These treatments were arranged in a randomized block design with three replications. The results of study revealed that addition of vermicompost prepared from inoculation of Trichoderma either of the substrata proved beneficial in order to maintain the plant population through out the crop period. The reduction in plant population (68%) was observed where the RDF of NPK alone was applied. The maximum plant height (43.50 cm.) and branches (11.2 per plant) were recorded under the use of vermicompost of soybean straw inoculated with Trichoderma + PSB + cow dung. Similarly, yield attributes pods per plant, seeds per pod and grain yield per plant was higher in same treatment. The maximum grain and straw yields of chickpea (15.08 and 18.52 q/ha) respectively was recorded under top ranking treatment. Vermicompost prepared from soybean substrata and simultaneously enriched with cow dung and inoculated with Trichoderma and PSB reduced the mortality rate of plants 48.9 per cent and enhanced the grain yield.

EFFICACY OF DIFFERENT MANAGEMENT TACTICS AGAINST EARLY BLIGHT OF TOMATO IN MID-HILLY AREAS OF UTTARAKHAND

S. BISWAS, VIVEKANAND*, S. RAVI AND R.C. MISHRA

Department of Plant Pathology and Entomology, College of Horticulture VCSGUUHF Bharsar

Tomato is one of the most popular warm season vegetable crop grown throughout the world because of its wider adaptability and suitability for variety of cuisines in fresh as well as in preserved form. Early blight is one of the most important foliar diseases of tomato; it is caused by *Alternaria solani* Sorauer. It may cause yield losses of up to 78% in India. The present experiment was conducted in Vegetable Research and Demonstration Block, College of Horticulture, VCSG, UHF Bharsar (Pauri Garhwal) Uttarakhand, during kharif season 2016. In this investigation, field experiments were conducted to evaluate the efficacy of two chemicals Carbendazim and Captan, two bioagents Trichoderma harzianum and Pseudomonas fluorescens, two botanicals Neem oil, Mustard oil and animal product Cow dung and Cow urine against *A. solani* Sorauer with different concentration (100, 200, 300, 400, 600, 800 ppm). Carbendazim proved best treatment in field condition for highest no. of fruits (19.56), maximum fruit weight (57.10 g) and minimum percent of fruit infection (23.83%) at 800 ppm as compare to other treatments like captan, Trichoderma harzianum, Pseudomonas

fluorescens and animal product. Similarly minimum disease intensity was recorded in carbendazim (46.40, 51.10 & 56.97%) at 75, 90 and 105 (DAT) respectively at 800 ppm concentration, followed by captan (49.20, 54.67 & 58.92%) and *T. harzianum*. (55.34, 63.88 & 69.56%) at 75, 90 and 105 (DAT) respectively

POTASSIUM DYNAMICS IN RESIDUE AMENDED RICE-WHEAT SOILS UNDER LONG-TERM POOR QUALITY WATER IRRIGATION

S. CHATTERJEE^{1*}, O.P. CHOUDHARY¹

¹Department of Soil Science, Punjab Agricultural University, Ludhiana, Punjab

The present research was conducted to study the influence of long-term poor quality water and crop residue incorporation on physico-chemical properties and potassium dynamics of the soil through a field investigation and an incubation study. The long-term experiment had 16 treatments involving four irrigation water qualities: canal water irrigation (SW1), sodic water (SW2), sodic water plus gypsum (SW3) and saline water (SW4). The crop residue treatments were wheat straw @ 6 t ha⁻¹ to rice crop (T1), rice straw @ 6 t ha⁻¹ to wheat crop (T2), both rice and wheat straw @ 6 t ha⁻¹ each (T3) and the unamended control (T4). Irrigation with SW2 and saline SW4 significantly increased soil pH, EC, soluble salts, sodium adsorption ratio (SAR), exchangeable sodium percentage (ESP) and CaCO₃, and decreased organic carbon while application of gypsum with sodic water decreased pH, SAR and ESP in soil after wheat and rice harvest in 2016-17. Bulk density increased with SW2 irrigation and soil depth and decreased with the addition of crop residues. Saline and sodic water irrigation lowered all the K fractions viz. water soluble K (WSK), exchangeable K (ExK), non-exchangeable K (NEK) in the soils, whereas application of crop residues increased these K fractions. The water soluble K and ExK decreased with depth while NEK and total K increased with soil depth. Incorporation of both rice and wheat residues (T3) significantly increased all the K fractions over the unamended control (T4). Simple Elovich model best represented the cumulative release of K as evidenced by higher R² values (≈0.98) and higher value of kinetics parameters than other models. Potassium concentration and uptake by wheat and rice grain was lowered when irrigated with saline and sodic waters while the Na content in grain and straw of both crops increased. Crop residue amendments improved rice and wheat yield as well as K uptake in saline and sodic water irrigated soils; the effects were pronounced in soils amended with both crop residues. The study showed that the adverse effects of saline and sodic irrigation on K fertility can be effectively managed by incorporation of crop residues.

Key words: Crop residues, potassium dynamics, rice-wheat, saline water, sodic water, soil properties.

PERFORMANCE OF PROMISING GENOTYPES OF GAILLARDIA (GAILLARDIA PULCHELLA L.) IN RESPECT OF GROWTH AND FLOWERING ATTRIBUTES

S. D. SALVE¹, S. G. BHALEKAR², YOGESH NILWARN³ AND NAGESH GAWADE⁴

^{1,2 & 3} College of Agriculture, Pune-05, MPKV, Rahuri, ⁴Junagadh Agricultural University, Junagadh-362001

The present investigation was carried out during the year 2016-2017 at Modibaug garden of Horticulture Section, College of Agriculture, Pune. The experiment was laid out in Randomized Block Design with three replications. The genotype MG-2-2 recorded significantly highest plant height (83.40 cm), (103.60 cm) and (110.00 cm) at 90, 120 and 150 days after transplanting respectively. The genotype MG-9-1 recorded significantly maximum plant spread at (E-W) direction (68.17 cm) and at (N-S) direction (59.40 cm) at 90 DAT. Significantly maximum numbers of primary branches per plant was recorded in the genotype MG-10-4 (19.15) and the maximum number of secondary branches per plant was recorded in the genotype MG-9-1 (54.51). The genotype MG-10-2 showed significantly early initiation of flowering (51.33 days) after transplanting. The genotype MG-6-2 showed early 50 percent flowering (62.24 days) after transplanting. The genotype MG-9-1 recorded significantly maximum flower diameter (6.02 cm) followed by the genotype MG-7-2 and MG-5-5 (6.00 cm) and both genotypes are on par with MG-9-1. Significantly more number of ray florets per flower were noticed in the genotypes MG-9-1 (156.53), MG-2-2 (155.80) and MG-6-2 (154.50). The genotype MG-2-2 recorded significantly maximum flower stalk length (17.92 cm). The flower stalk thickness of different genotypes of gaillardia ranged from 2.8 to 3.0 mm but the treatment differences were non-significant for this character.

Key words: Gaillardia genotypes, growth and flowering attributes.

PLANT GROWTH PROMOTING RHIZOBACTERIA (PGPR) IN AGRICULTURAL SUSTAINABILITY

S. DILIP KUMAR REDDY¹, K. SREE PAVAN², B. SUVARCHALAREDDY³

¹ College of Agriculture, SKRAU, Bikaner, Rajasthan, ² College of Agriculture, KAU, Thrissur, Kerala, ³ S.V. Agricultural College, ANGRAU, Tirupati, Andhra Pradesh

The need of today's world is high production of the crop as well as fertility of soil to get in an ecofriendly manner. Both biotic and abiotic factors are affecting plant health very much and causing greater losses in yields. Now a days, the utilization of chemical fertilizers in the

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

agriculture is elevated to increase yield and to kill pathogens, pests, and weeds and simultaneously which shows harmful impact on the ecosystem. Because of current public concerns about the side effects of agrochemicals, there is an increasing interest in improving the perception of cooperative activities among plants and rhizosphere microbial populations. So, there is an urgent need of biological agents to accept worldwide. The use of plant growth promoting rhizobacteria (PGPR) is a better alternative to solve this problem. They play an vital role either direct or indirectly to increase in soil fertility, plant growth promotion, and suppression of phytopathogens for development of ecofriendly sustainable agriculture. The addition of ice-nucleating plant growth promoting rhizobacteria ought to be a fantastic science for improving plant growth at low temperature. So, there is a need to start new generation with environment friendly approach to increase crop production and for better health.

Key words: plant growth promoting rhizobacteria, ecofriendly, rhizosphere, sustainable agriculture

PLANT HEIGHT AND DRY MATTER OF FENUGREEK (*TRIGONELLA FOENUM-GRÆCUM*) AS INFLUENCED BY PHOSPHORUS, ZINC AND ZINC SOLUBILIZER

S. KUMAWAT, R. SAMMAURIA AND P. KUMAWAT

Rajasthan Agriculture Research Institute, Durgapura (SKNAU, Jobner), Rajasthan 302018, Rajasthan Agriculture Research Institute, Durgapura-Jaipur (SKNAU, Jobner), Rajasthan Division of extension, SKNAU, Jobner; Rajasthan

Fenugreek (*Trigonella foenum-græcum* L.) popularly known by its vernacular name “methi” has been in culinary and medicinal uses due to its restorative and nutraceutical properties for more than 2500 years. Phosphorus deficiency is usually the most important single factor which is responsible for poor yield of legume crops on all types of soil. Zinc is one of the imperative micronutrients required relatively in small concentrations (5-100 mg/kg) in tissues for healthy growth and reproduction of plants. Microbes are potential alternate that could cater plant zinc requirement by solubilising the complex zinc in soil. An experiment was conducted at *Rajasthan Agriculture Research Institute (RARI), Durgapura-Jaipur*, during *rabi* and *kharif* seasons of 2015-16 and 2016-17. The treatments comprises of four levels of phosphorus (0, 20, 40 and 60 kg P₂O₅/ha) and six treatments of zinc and zinc solubilizer [0, 2.5 and 5.0 kg Zn/ha, zinc solubilizer (*Bacillus endophyticus*), 2.5 kg Zn/ha + zinc solubilizer & 5 kg Zn/ha + zinc solubilizer] in split plot design with three replications. A uniform dose of 20 kg N/ha along with phosphorous and zinc as per treatments were drilled through diammonium phosphate and zinc sulphate (21%), respectively. To compensate the sulphur obtained from different levels of Zinc compensatory dose of sulphur will be applied through elemental sulphur before 21 days of sowing. The fenugreek variety Rmt-305 was sown on 03 November 2015 and 15 November 2016, with 30 cm row to row and 10 cm plant to plant spacing. Results revealed that application of 40 kg P₂O₅/ha and 5 kg Zn/ha + zinc solubilizer resulted in significant increase in plant height and dry matter. Application of 60 kg P₂O₅/ha and 5 kg Zn/ha + zinc solubilizer increased 19.4 % and 21.5 % higher plant height of fenugreek, during 2015-16 and 40.1 % and 31.3 %, during 2016-17 when compared with control.

Key words: Dry matter, Fenugreek, Plant height, Phosphorus, Zinc and Zinc solubilizer

APPLICATION OF BIOCHAR AS A SOIL AMMENDMENT FOR SUSTAINABLE AGRICULTURE AND ENVIRONMENT

S.LAVANYA

Advance Institute Of Science And Technology

Biochar is produced by the pyrolysis of biomass, contributes to carbon sequestration and also provides usable biofuels in addition to its creation. The majority of the biomass used in biochar manufacturing is obtained from the waste produced from farm fields like the leaves and stalks of corn, sorghum, soybean etc. as well as diseased and fallen trees removed by forestry. If these feedstocks were left to decompose naturally a higher percentage of carbon content would be converted to carbon dioxide and released into the atmosphere, carbon dioxide being a greenhouse gas leads to global warming. On the other hand the conversion of biochar locks the carbon in a stable form that will not react with oxygen to produce carbon dioxide. This carbon based porous material helps to improve soil health due to the high organic content, causes retention of the nitrogen and phosphorus fertilizer components by preventing their leaching into the ground water and also provides environments for beneficial microbes to grow thus causing higher crop yields along with increased cation exchange capacity.

VERMICOMPOST AN EXCELLENT OPTION FOR SUSTAINABLE NUTRIENT MANAGEMENT

S. NARAYAN, F.A. KHAN, AJAZ A MALIK, K. HUSSAIN, M. AMIR¹ AND ASTHA²

Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir, Shalimar 190025, Distt. Srinagar (J&K), ¹CSAUAT, Kanpur; ²NDUAT, Faizabad

Indiscriminate use of chemical fertilizers and pesticides for the last few decades made the soil unproductive with loss of biodiversity and the environment polluted. So, rejection or reduced use of chemicals and practice of organic farming for recovery of soil health, increase in food grain production and biodiversity conservation have been suggested. Organic manures play an importance role in crop

production and sustainable agriculture development. Vermicompost has been emerging as an important source in Supplementing/substituting chemical fertilizers in agriculture. Besides higher concentration of available nutrients (macro, secondary and micro) than the ordinary FYM. Millions of tones of agricultural and industrial wastes are discarded every year at considerable financial and environmental cost. Instead of discarding the food scraps and wastes, we can recycle these with the help of earthworms. Vermiculture technology involves the beneficial use of earthworms for the production vermicompost from agricultural and industrial wastes which is rich in macronutrients, micronutrients and beneficial micro-organisms. Agriculture provides plenty of wastes amounting to nearly 320 million tones annually. With the help of vermicomposting we can convert all such wastes to wealth by producing highly marketable castings. Integrated use of vermicompost alongwith FYM, biofertilizer and chemical fertilizer in french bean may improve soil health and production by saving costly inorganic fertilizers. Research reveals that vermin-technology has a prominent role in the development of ideal soil structure, nutrient and water management, waste management, better crop response, plant disease and pest control pollution abatement and production of chief animal protein in the form of earthworms for poultry farming and aquaculture. The fruits, flowers and vegetables and other plant products grown using vermi-compost are reported to have better keeping quality. Organic manures play an importance role in crop production and sustainable agriculture development.

EFFECT OF LEVELS AND SOURCES OF ZINC ON ZINC FRACTIONS IN SOIL AND PRODUCTIVITY OF RICE (*ORIZA SATIVA* L.)

S.P. SINGH, AKASH KUMAR AND PANKAJ CHAURASIYA

"Department of Soil Science & Agricultural Chemistry", Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut 250110

A field trial was conducted during *kharif* 2016 to investigate the effect of levels and sources of zinc on zinc fractions in soil and productivity of rice (*Oriza sativa* L.). To this effect ten treatment consisting various zinc fraction were tested in a randomized block design (RBD) with three replication. The area lie at a latitude of 29° 40' North and longitude of 77° 42' East with an elevation of 237 meters above mean sea level. The soil of experimental field was well drained, sandy loam in texture (sand 52.3 %, silt 28.2 % and clay 19.5 %) and slightly alkaline in reaction (pH 8.03). It was low in available Zinc with an electrical conductivity (1:2.5, soil: water extract) of 0.21 dSm⁻¹. The data on growth, yield and its contributing traits were calculated on plot area basis (15 m²), whereas content, uptake of nutrients at various stages and NUE along with Zinc fractions were recorded as per the standard procedure. Remarkable effect was noted where growth attributes (plant height, numbers of tillers), yield attributing traits (panicles length, number of grains per panicle and test weight), yields viz., grain, straw and biological and uptake of (ZnSO₄.7H₂O @ 7.5 kg ha⁻¹). Although, this treatment also noticed imminence improvement in soil available Zinc fraction and organic carbon. Moreover, significantly highest grain (40 q ha⁻¹) and biological yield (106.60 q ha⁻¹) was registered under the application of (ZnSO₄.7H₂O @ 7.5 kg ha⁻¹), at maximum tillering and panicle initiation respectively as compared to all other treatments. While, higher straw yield (66.6 q ha⁻¹) was produced under application of (ZnSO₄.7H₂O @ 7.5 kg ha⁻¹), at maximum tillering and panicle initiation respectively. Thus (ZnSO₄.7H₂O @ 7.5 kg ha⁻¹), at maximum tillering and panicle initiation, respectively, is best option for achieving maximum yield and Zinc use efficiency. Besides, it will also improve soil health.

Key Words: Texture, electrical conductivity, Zinc fraction and Zinc use efficiency etc.

BIOTECHNOLOGICAL APPROACHES IN INTEGRATED PEST MANAGEMENT

S. RAMESH BABU*, S. V. S. RAJU, DEEPAK KR. JAISWAL AND KAMAL RAVI SHARMA

Department of Entomology and Agril. Zoology, Institute of agricultural Sciences, Banaras Hindu University, Varanasi- 221 005

World agriculture is passing through a distinct phase of transformation, called the 'Second Green Revolution' in which modern biotechnology enables the production of genetically modified (GM) crops that are claimed to help and resolve the pressing problems of food security, malnutrition and abject poverty in different parts of the world. Crop losses caused by pests are a major problem in both developed and developing countries. Over the years the extensive use of pesticides has led to pesticide resistant insects, reduction in beneficial insect populations (Natural enemies) and many harmful effects to humans and the environment. Genetic modification through biotechnology can potentially provide a much larger array of novel insecticidal genes that are new beyond the scope of conventional breeding. Modern agricultural biotechnology or genetic engineering includes manipulation of the genetic make-up of organisms for use in the production or processing of agricultural products. The biotechnological tools have been applied to study various issues such insect identification, insect control and insect genetic relationships. It has a significant role in improving efficacy, cost-effectiveness and in expanding the markets for the bio insecticides. Biotechnology provides opportunities for the development of insect natural enemies conferring beneficial traits such as pesticide resistance, cold hardiness and sex ratio alteration. Genetic manipulation of *Bacillus thuringiensis* (*Bt*) genes encoding for proteins toxic to insects offers an opportunity to produce genetically modified strains with more potent and transgenic plant expressing *Bt* toxin. In addition to the *Bt* delta-endotoxin, several proteins that are effective against certain

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

insects such as the vegetative insecticidal proteins (VIP), alpha-endotoxin, a variety of secondary metabolites and proteins of plant origin are amenable to genetic manipulation. The concept of DNA fingerprinting has been recently used in insect field. The chemical structure of everyone's DNA is the same. Ecological agriculture could be achieved not only through proper agricultural practices but also through continuous research and development of new technologies, particularly agricultural biotechnology, which is probably a very important investment to achieve greater effectiveness in the world market.

STUDIES ON ANTIOXIDANT PROPERTY OF BEETROOT (*BETA VULGARIS L.*) MIXED PANEER WHEY BEVERAGE

S. S. GORE* AND P. V. PADGHAN

Department of Animal Husbandry and Dairy Science, Vasantrao Naik Marathwada Krishi Vidyapeeth, College of Agriculture, Latur-413 512

Milk the first nutrient of the new born, provides adequate amounts of all nutrients required by infants. The milk proteins are divided into two main groups' caseins and whey proteins. Milk whey proteins have been demonstrated to have antioxidant properties and hypothesized their use in the food industry as a natural conservant. Beetroot *paneer* whey beverage was prepared from different proportions of beetroot extract using with *paneer* whey. The product obtained was subjected for chemical analysis. The average antioxidant activity was 0.42 and 2.68 of *paneer* whey and beetroot extract respectively. It was further observed that as the antioxidant activity in the beetroot extract more than the *paneer* whey. The average antioxidant activity of beetroot whey beverage was 0.37, 0.85, 0.96 and 0.98 for treatment T₁, T₂, T₃ and T₄, respectively. The highest antioxidant activity was recorded for treatment T₄ i.e. 0.98 ± 0.008^a TEAC (μmol)/mg protein). Antioxidant activity were at par with each other in treatment T₄ and T₃ in which whey is used in 75 and 80 parts and beetroot extract as 25 and 20. The lowest antioxidant activity was recorded for treatment T₁ i.e. 0.37 ± 0.008^b TEAC (μmol)/mg protein. The quantity of beetroot extract used in it is directly proportional to antioxidant activity.

Key word: Antioxidant, beetroot whey beverage and *paneer* whey.

ISOLATION OF ENTOMOPATHOGENIC NEMATODES (EPNS) FROM RICE ECOSYSTEMS OF TRICHY DISTRICT, TAMIL NADU AND THEIR EFFICACY ON RICE LEAF FOLDER, *CNAPHALOCROCIS MEDINALIS* GUENEE (LEPIDOPTERA: PYRALIDAE)

S. THANGAVEL^{1*}, R. SELVAM² AND T. SENTHIL KUMAR³

^{1*}Dept. of Agrl. Entomology, B A College of Agriculture, Anand Agricultural University, Anand, Gujarat, India 388110, ²Dept. of Soil Science and Agricultural Chemistry, ³Horticulture Research Station, Pechiparai, Tamil Nadu Agricultural University, Tamil Nadu, India

The present study was conducted for surveying the entomopathogenic nematodes from the selected rice ecosystems of Trichy district, Tamil Nadu, India. A total of 270 samples were collected from the field used for isolation of nematodes during 2014-2015. Hence, two different species (*Steinernema* & *Heterorhabditis*) of entomopathogenic nematodes were isolated from the soil samples using the Corcyra baiting technique. Now a days we are using more pesticides to control pest which are harmful to human, soil and micro organisms. Hence to mitigate the harmful effects of chemical pesticides, entomopathogenic nematodes (EPNs) plays important role in controlling the rice leaf folder and the other lepidopteran pests. Here we tested leaf folder mortality to different EPNs treatments with comparison to time (24, 48 and 72 hrs after). The results of the present investigation indicated that effectiveness of the both entomopathogenic nematodes on rice leaf folder larvae mortality was equal. But the nematode recovery from the dead rice leaf folder larvae was high in *Heterorhabditis* (159 nematode/ 5 leaf folder larva) compared to *Steinernema* (153 nematodes / 5 leaf folder larvae). But in case of adult leaf folder moths the effectiveness of the *Steinernema* was high (3 dead moths/ 5 moths) compared to *Heterorhabditis* (2 dead moths / 5 moths) , but the nematode recovery from the dead rice leaf folder adult moths was high in *Heterorhabditis* (57 nematodes / adult) compared to *Steinernema* (47 nematodes/ adult). Hence, use of the EPNs is recommended to reduce the lepidopteran pests of rice and also to conserve the natural enemies and ecofriendly nature in the rice ecosystem.

Key words: Rice, eco systems, leaf folder, entomopathogenic nematodes, mortality

THE CRISPR-CAS9 SYSTEM: A CRISPER DEBATES IN GENOME EDITING

S. VIJAY KUMAR, SUNAYANA AND MEENAKSHI RATHI

Department of Genetics and Plant Breeding, CCS Haryana Agricultural University, Hisar (Haryana) India- 125004

The CRISPR-Cas9 (clustered regularly interspaced short palindromic repeats with CRISPR associated protein) is a rapidly developing genome editing technology that is easy to design, highly specific, efficient, robust, extremely versatile and well suited for high throughput gene editing for a variety of cell types and organisms. The system was first identified in bacterial immune system. It was developed as a gene editing technology in 2013. Site specific modification is achieved by a single guide RNA (usually about 20

nucleotides) that is complementary to a target gene or locus and anchored by a protospacer-adjacent motif. This targeted DNA is then cleaved by Cas9 nuclease to generate double-strand breaks (DSBs), followed by subsequent DNA repair via non-homologous end joining (NHEJ) or homology-directed repair (HDR) mechanisms leading to the disruption of gene functions in plants. Multiplexed CRISPR-Cas9 exploits multiple gRNA sequences for simultaneous editing of multiple sites within the same genome. Development of genetically edited (GE) crops provides a sustainable productive agriculture for better feeding of rapidly growing population in a changing climate. In this chapter, we briefly survey the history of the CRISPR/Cas9 system invention and its genome editing mechanism and briefly emphasizes on the potentiality of this gamechanging technology.

Keywords: Genome editing, CRISPR/Cas9, guide RNA, DSBs, DNA repair, NHEJ, HDR and GE crops.

AN ECONOMIC ANALYSIS OF RICE BASED CROPPING SYSTEMS IN RATNAGIRI DISTRICT OF MAHARASHTRA S.A. DIWATE, S.C. PHUGE *, S.J. MHATARE, J.M. YADAV, V.N. ANAPAND J.M. TALATHI

Department of Agricultural Economics, Dr. B.S. Konkan Krishi Vidyapeeth, Dapoli 415712, Dist. Ratnagiri, Maharashtra, India.

The study was conducted at Department of Agricultural Economics, Dr. B.S. Konkan Krishi Vidyapeeth, Dapoli Dist. Ratnagiri with objectives to estimate cost, return and profitability of rice based cropping systems in Ratnagiri district of Maharashtra. In this study, primary data were collected from 120 farmers by personal interview method with the help of pre-tested schedule. Simple tabular analysis was applied for the comparison of yields and inputs used by the farmers. Economics of individual crop and crop combination was worked out. The standard cost concepts used in farm management studies. Results showed that in study area six farming systems followed by farmers. From the finding of present study, total cost higher found in FS-I (Rs. 109617) and least total cost in FS-IV (Rs. 68436). The per farm gross returns were maximum in FS-III (Rs. 148377) followed by FS-II (Rs. 128837), FS-I (Rs. 126304), FS-VI (Rs. 115794), FS-IV (Rs. 87787) and FS-V (Rs. 76876), which indicated higher returns in farming systems in which irrigated plantations were undertake. Among all the farming systems FS-III, FS-II and FS-VI were found highly profitable than other farming systems. The FS-II (Paddy+Pulses+Irrigated plantation) and FS- III (Paddy + Irrigated plantations) plays a major role in profitability of the farming systems. Which underline its importance and need to concentrate on these enterprises for making farming systems more profitable. Therefore, the proper balance between livestock enterprises and crop enterprises need to be encouraged to bring remaining farming systems more profitable.

Keywords: Rice, farming systems, cost and profitably.

ROLE OF HOST PLANT RESISTANCE IN INTEGRATED PEST MANAGEMENT

S.K. BEHERA^A

Department of Entomology, Indira Gandhi Krishi Vishwavidyalaya, Raipur, Chhattisgarh

Host plant resistance (HPR) is a cumulative, effective and eco-friendly method of pest management. HPR is usually specific against a particular insect pest or pest complex and does not exert any adverse effect on non-target or beneficial organism. The application techniques adopted by farmers does not need any skill and also not require much higher cost which is the most attractive trait of HPR. HPR will not only cause a major reduction in pesticide use and slowdown the rate of development of resistance to insecticides in insect populations, but also lead to increased activity of beneficial organisms and reduction in pesticide residues in food and food products. Extensive progress has been made in identification and development of crop cultivars with resistance to the major pests in different crops. There is a need to incorporate resistance genes into high-yielding cultivars with adaptation to different agro-ecosystems. An insect resistance variety with high yielding potential should available for cultivation by the farmers.

KEY WORDS: Host plant resistance (HPR), Integrated pest management (IPM), Cumulative, Eco-friendly, Resistance genes.

EFFECT OF SULPHUR ON GROWTH, YIELD AND QUALITY OF LINSEED (*Linum usitatissimum* L.)

S.P. BAINADE^{1*}, N.P. NAVNAGE²

^{1*}*Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola (MH), 444104, ²Indira Gandhi Krishi Vishwavidyalaya, Raipur (CG), 492012*

The present investigation entitled "Effect of sulphur on growth, yield and quality of linseed (*Linum usitatissimum* L.)" was conducted at Department of Agronomy farm, College of Agriculture, Nagpur during *rabiseason* 2017-18. The soil was clayey in nature with pH 7.9 indicating slightly alkaline in reaction, low in available nitrogen; medium in available phosphorus and very high in available potassium. The Experiment was laid out in Randomised Block Design with T₁- RDF (60:30:00 NPK kg ha⁻¹), T₂- RDF + 15 Kg S ha⁻¹ through gypsum, T₃- RDF + 20 kg S ha⁻¹ through gypsum, T₄- RDF + 25 kg S ha⁻¹ through gypsum, T₅- RDF + 15 kg S ha⁻¹ through bensulf, T₆- RDF + 20 kg S ha⁻¹ through bensulf, T₇- RDF + 25 kg S ha⁻¹ through bensulf, T₈- No Fertilizer (control). There was eight treatments replicated thrice. The results of the study indicated that application of RDF + 25Kg S ha⁻¹ through bensulf recorded higher growth, yield attributing characters and quality. GMR, NMR and B: C ratio were significantly higher in the treatment RDF + 25 kg S ha⁻¹ through

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

bensulf. Growth contributing character viz., plant height, number of branches plant⁻¹, no. of days to 50% flowering, dry matter plant⁻¹ and yield contributing characters such as grain yield plant⁻¹, straw yield plant⁻¹, biological yield, harvesting index, seed and straw yield (kg ha⁻¹) were significantly higher by the treatment RDF + 25 kg S ha⁻¹ through bensulf (T₇).

Keyword: Effect, Sulphur, Growth, yield, linseed.

MICRO-IRRIGATION SYSTEM FOR SUSTAINABLE AGRICULTURE

¹SABREENAASHRAF, ²SYED JAWAD-UL-HAQ

¹Division of Entomology, SKUAST-K, ²Division of Basic Science and Humanities, SKUAST-K

Micro-irrigation, also called localized irrigation, low volume irrigation, low-flow irrigation, or trickle irrigation is an irrigation method with lower pressure and flow than a traditional sprinkler system. Low volume irrigation is used in agriculture for row crops, orchards, and vineyards. It is also used in horticulture in wholesale nurseries, in landscaping for civic, commercial, and private landscapes and gardens, and in the science and practice of restoration ecology and environmental remediation. Micro-irrigation has high uniformity with water supply. Though, uniformity alone cannot accomplish the motive of irrigation. In India a high proportion of water resources are used for agricultural production, so micro-irrigation systems designed with high uniformity is must to achieve water conservation as well as environmental protection. For drip irrigation, the best ranking is for systems having lower costs, mainly with double rows per lateral and larger emitter spacing. Comparing surface and drip irrigation systems, despite low cost, drip alternatives may lead to 28-35% water saving relative to improved graded furrows, and increase water productivity from 0.43 kg m³ to 0.61 kg m³, surface irrigation provides higher farm returns. The drip method of irrigation has been found to have a significant impact on resources saving, cost of cultivation, yield of crops and farm profitability. Drip irrigation is completely suitable for cultivating vegetable crops that are mostly cultivated by small farmers. It would curtail the distress of the small farmers as well. The Agricultural sector is the largest user of water, followed by the domestic sector and the industrial sector. Using sprinkler irrigation system, 30.8% and 28.3% higher water use efficiency and 21.1% and 9.0% more water application efficiency was achieved as compared furrow irrigation system. Water scarcity in various parts of the country has created awareness about micro-irrigation systems and its implementation results in significant economic and social benefits in the country. The saved water can be used to increase the area under irrigation or for the reclamation of degraded/ waste land. Hence, micro-irrigation has been considered as an innovative technology for sustainable agricultural growth.

Key Word: Micro irrigation, Water use efficiency, Drip irrigation, Sprinkler irrigation

EFFECT OF FRUIT THINNING ON QUALITY OF PEACH (*PRUNUS PERSICA* (L.) BATSCH) CV. RED JUNE

***SACHIN DEVLAL, VJAY BHAWARDWAJ¹, SHWETA UNIYAL² AND A.C. MISHRA³**

Department of Horticulture, Dolphin (PG) institute of natural bio-medical and natural science Dehradun, Manduwala, Department of Horticulture, V.C.S.G. Uttarakhand of Horticulture and Forestry, Bharsar Ranichauri Campus 249199 (Tehri Garhwal) Uttarakhand¹, Department of Horticulture, GBPUA&T Pantnagar, Uttarakhand², Department of Horticulture, Banda Agriculture University and Technology, U.P.³*

The present investigation was carried out during the year 2013 in the Research Block of Department of Horticulture, VCSG Uttarakhand University of Horticulture and Forestry, Ranichauri, Tehri Garhwal, Uttarakhand. The experiment was laid out in a Randomized Block Design (RBD) with three replications and 13 treatments. The fruit thinning treatments consisted of foliar spray of NAA at 25, 50 and 75 ppm, ethrel at 100, 200 and 300 ppm, thidiazuron at 10, 20 and 30 ppm at two weeks after petal fall and hand thinning of fruits to the intensity of 10, 20 and 30 percent at pea stage and unthinned control. The result revealed that foliar spray of ethrel @ 300ppm significantly increased the fruit thinning (29.05 %). Hand thinning of 30% fruits recorded significantly higher values for increased tree height (43.63 cm), tree spread (41.66 cm), tree volume (4.13 m³), shoot extension growth (52.61 cm) and leaf to fruit ratio (36.71) over the control. Whereas, tree sprayed with NAA @ 75 ppm resulted least fruit drop (5.87 %) over the control. Thus, it can be concluded that spray of ethrel @ 300 ppm was found as the most effective chemical thinner when applied two weeks after petal fall in peach cv. Red June as it produced superior quality of fruits.

CROP RESIDUE MANAGEMENT FOR NUTRIENT CYCLING AND IMPROVING SOIL PRODUCTIVITY

SACHIN DHANDA

Department of Soil Science, CCS Haryana Agricultural University, Hisar-125004

Crop residue is defined as the vegetative crop material left on the field after a crop is harvested, pruned or processed. India being an agriculture dominant country produces more than 500 million tons of crop residue annually. These residues are used as animal feed, for thatching of homes and as a source of domestic and industrial fuel. A large portion of unused crop residue are burnt in the fields primarily to clear the left over straw and stubbles after the harvest. Non availability of labour, high cost of residue removal from the field and

increasing use of combines in harvesting the crops are main reasons behind burning of crop residues in the fields. Burning of crop residues causes environmental pollution which is hazardous to human health, produces greenhouse gases causing global warming and results in loss of plant nutrients like N, P, K and S. Therefore, appropriate management of crop residues assumes a great significance. The residues of rice, wheat, cotton, maize, millet, sugarcane, jute and rapeseed-mustard are typically burnt on-farm across different states of the country. The problem is more severe in the irrigated agriculture, particularly in the mechanized Rice-wheat cropping system of the north-west India. Crop residue can be managed by following strategies incorporation of crop residue in soil, use of crop residue for compost / vermi-compost / FYM / mushroom cultivation, use in power generation and production of ethanol, use for paper/board and packing material, promotion of collection of crop residue for feed bricks making and its transport to fodder deficient areas. The crop residue incorporation improves physical, chemical, and biological properties of soil. In long term incorporation of crop residue increases the nutrient cycling and productivity.

Keywords: Crop residue, environmental pollution, vermi-compost, productivity.

“ROLE OF FLORICULTURE AS THERAPEUTIC VALUE IN MODERN ERA”

SACHIN GOKULDAS GAONKAR¹ AND NAGMARAFIQUE SURVE²

¹Chaudhary Charan Singh Haryana Agricultural University, India, ²Dr. Balasaheb Sawant Konkan Krishi Vidyapeeth, India

Floricultural plants are grown both in indoor and outdoor gardens and in landscaping projects, for beautification purpose. Besides, horticultural plants have positive physiological impact on human beings. These plants are helpful in air purification, water conservation, avoiding soil erosion, and providing shelters to natural fauna. Hence, these plants play important role in proper functioning of ecosystems. In modern era, people are becoming more conscious about health and for maintaining good health a trend has emerged to use medicinal plants and plants related activities instead of using synthetic drugs due to side effect and contraindication in use. The colour, shape, smell, touch and taste of the plants stimulate the sensory organs leading the brain to activate and release several enzymes or chemicals which enhances mood and make the people to feel comfortable. People of all age groups when exposed to plants have both positive thinking as well as positive emotions. The students of a school with gardening facilities feel much comfortable and confident and also show improvement in learning skills. Learning abilities, concentration, creativity communication skills, and decision making and leadership qualities improves subsequently. The overall performance of students engaged in gardening activities was higher as compared to students of a school lacking gardening facilities. Scenic beauty of gardens attracts people to visit repeatedly for longer time and spend quality time with nature. Hence, gardens and gardening activities which allow interaction with nature can have positive impact on psychology as well as on physiology and thus help to live better life.

EFFICACY AND PHYTOTONIC EFFECT OF FIPRONIL 0.3 G(MAHAVER 0.3GR) AND 5 SC (MAHAVER 5 SC) IN RICE CROP (ORYZASATIVAL.)

SACHIN KUMAR¹ HARIKESH SINGH^{2*} AND SHALINI SINGH VISEN³

Glocal University Saharanpur (U.P.), Gochar Mahavidyalaya, Rampur maniharan-Saharanpur (U.P.), Amity Institute of Organic Agriculture, Amity University, Uttar Pradesh

The experiment was conducted to evaluate the Efficacy and Phytotonic effect of Fipronil 0.3 G (Mahaveer 0.3GR) and 5 SC (Mahaveer 5 SC) in rice crop (*Oryza sativa* L.) at Pilkhani (Rampur Maniharan), Saharanpur (U.P.). To observe phytotonic and insecticidal properties of fipronil, data were recorded on plant height, number of roots/plant, root length, number of tillers / hill and insect infestation at 15 days interval. Observations were started from 20 days after transplanting and continued up to maturity. The experiment was conducted in Randomized Block Design with Six treatments on rice variety Basmati 999. Fipronil 0.3G (Mahaveer 0.3 GR) and Fipronil 5SC (Mahaveer 5 SC) insecticide alone and in combinations were used. Fipronil 0.3G @ 25 kg/ha at 20 DAT days after transplanting enhanced growth parameters and combination of it with spraying of 5SC @ 1000 ml/ha at 45 days after transplanting acted as boosting dose and also reduces insect infestation resulting maximum yield. Therefore, Fipronil 0.3G @ 25 kg/ha at 20 DAT followed by Fipronil 5SC @ 1000 ml/ha at 45 DAT was best for reducing the insect infestation and improving the plant growth and yield recommended for better response.

KEYWORDS: Efficacy, Fipronil 5 SC, Fipronil 0.3GR, Growth parameters, and Rice

PERFORMANCE OF MAJOR FOOD GRAINS PRODUCTION IN TRIPURA: AN OVERVIEW

SADDAM HOSSEN MAJUMDER*, PRODYUT BIJOY GOGOI AND NIVEDITA DEKA****

Department of Agricultural Economics, Faculty of Agriculture, Assam Agricultural University, Jorhat-785013, Assam, India

The agro climatic condition of Tripura offers immense potential for production of number of food grains in the state. The production of food grains provides gainful employment for small farmers and agricultural labor throughout the year. In this study an attempt were made to estimate the gap between production and requirement of food grains in the state. The secondary data on major food grains in the state

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

over the decade (2001-2014) were collected. Compound growth rate, moving averages ratio and regression analysis was done to achieve the objective. The annual growth rate in per cent for yield of rice in Tripura is 1.87 per cent which is at par with the growth rate of yield of rice in national level (1.87%). Similarly, maize and pulses growth rate (2.46% and 1.02%) were positive and it is mainly because of the introduction of high yielding varieties but the yield of pulses in the state was lesser than the national level. However, the growth rate for production of wheat (-10.48%) and oilseeds (-0.41%) in the state were negative as the farmers are not very much willing to grow wheat and oilseeds extensively. In the year 2014-15, gap reduced to 0.19 lakh tons (LT) with production and requirement of 8.60 and 8.79 LT respectively, whereas the production and requirement was 6.12, 7.66 LT, respectively in 2004-05. The results showed that there was significant growth of food grains production in the state. The state has potentiality for the reducing the gap between production and requirement of food grains which showing the possibility of value addition through establishing processing units in the state that would help to boost farmers income and employment. Hence, government initiatives along with growers and processors interest needs to be developed for exploring the vast potentiality of this sector in the state.

Key word: Food grains, availability, gap, moving averages, Tripura

INTEGRATED MANAGEMENT OF WEB BLIGHT DISEASE OF MUNGBEAN INCITED BY *RHIZOCTONIA SOLANI* KÜHN

SADHNA CHAUHAN*, L.B. YADAV

Department of Plant Pathology, College of Agriculture, G B Pant University of Agriculture and Technology Pantnagar

Mungbean or Green gram [*Vigna radiata* (L.) Wilczek] is one of the most important pulse crops of India. Web blight disease caused by *Rhizoctonia solani* Kühn [*Thanatephorus cucumeris* (Frank) Donk] is one of the major serious constraints in its production causing heavy yield losses. Investigations were undertaken with an objective to develop suitable management strategy against web blight disease of mungbean. *In vitro*, Propiconazole was most effective against *R. solani* showing 93.33 per cent inhibition at 20 ppm concentration. Among the botanicals, Calotropis @ 35 per cent was most effective in mycelial growth inhibition of *R. solani* i.e. 86.00 per cent. *Trichoderma harzianum* showed better performance over *Pseudomonas fluorescens* in inhibiting mycelial growth of *R. solani* i.e. 61.29 per cent. Under controlled glasshouse conditions, seed treatment with Thiram+Carbendazim (2:1) @ 3 g/kg seeds followed by three foliar sprays of Propiconazole @ 0.1 per cent at 15 days interval gave maximum reduction in web blight disease severity i.e. 70.47 per cent. Under *in vivo* conditions, three foliar sprays of Propiconazole @ 0.1 per cent at 15 days interval gave maximum reduction in disease severity and maximum per cent increase in grain yield over check i.e. 65.54 per cent and 61.94 per cent, respectively.

CHECKLIST OF ACRIDIDAE (ACRIDOIDEA) OF UTTAR PRADESH

SAHAR MOBIN AND MOHD. KAMILUSMANI

Section of Entomology, Department of Zoology, Aligarh Muslim University, Aligarh 202002

Grasshoppers and locusts have long term association with human beings as they have been the major pest of almost every type of vegetation. They belong to suborder Caelifera under order Orthoptera. They destroy crops over a wide area when they swarm in millions as locusts. Due to the devastating effect they can also be the reason of famine. Even in small number they can be serious pests. The Acrididae are the major group of grasshoppers, containing about 6,701 valid species of the 8,132 species out of whole Superfamily Acridoidea (Cigliano et al., 2017). Due to great significance of Acridids as important agricultural pests, it is aimed to prepare a checklist of Acridid fauna of Uttar Pradesh, India. Therefore, a checklist of Acrididae of Uttar Pradesh was prepared in light of distributed data and published literature gathered from various resources and in addition to identified specimens deposited in Department of Zoology, Aligarh Muslim University, Aligarh. A sum of 78 species/subspecies were recorded comprising of 49 genera and 12 subfamilies. The most predominant subfamily was observed to be Oedipodinae. Species were arranged under their respective subfamilies and their percentage of occurrence was calculated subfamily wise.

Keywords: Acrididae, Pests, Checklist, Uttar Pradesh

APPLICATION OF AMELIORATION TECHNOLOGY IN SOIL SUSTAINABILITY

SAI SINDHU

E-mail : sindhusai192@gmail.com

The impacts of climate change and population growth are the increasing human pressure on land forces conversion of natural landscapes to agricultural fields and pastures while simultaneously depleting land currently under agricultural use. Therefore, a brutal loop develops; further aggravating climate change, soil degradation, and erosion, loss of soil organic matter and leaching of nutrients. Therefore, sustainable concepts for increased crop production are immediately needed to lower pressure on soils, in order to reduce or prevent the negative environmental impacts of rigorous agriculture. One efficient way to increase organic matter in soil is amelioration in soil like compost, biochar, Fly ash, Red mud, Phosphate rock and other rock minerals, etc. On the one hand, growth of livestock breeding

and intensification of crop production has occurred while an increasing shortage of resources, i.e. fossil fuels, fossil nutrients stocks and arable land, can be recognized. On the other hand, urbanization and growing population interconnected with an increased amount of waste output is responsible for environmental hazards and pollution. Therefore, soil amelioration became an efficient means of waste processing and environmental improvement.

EFFECT OF INTEGRATED NUTRIENT MANAGEMENT ON GROWTH CHARACTERS OF CROPS UNDER VARIOUS OAT-LATHYRUS INTERCROPPING SYSTEM

SAIKAT BISWAS^{1*}, K. JANA¹, A.M. PUSTE¹

¹*Department of Agronomy, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, Nadia, West Bengal*

One field experiment was conducted at Central Research Farm, Gayeshpur, Bidhan Chandra Krishi Viswavidyalaya, Nadia, West Bengal during *Rabi* season of 2015-16 and 2016-17 to evaluate the effect of integrated nutrient management on various growth characters of oat and lathyrus under different cereal-legume based cropping system. The experiment was placed in split plot design with 3 replications comprising 4 levels of cropping system (CS₁- Sole oat, CS₂- Sole lathyrus, CS₃- Intercropping of oat with lathyrus in 3:2 row ratio and CS₄- Intercropping of oat with lathyrus in 3:3 row ratio) in the main plot and 4 levels of nutrient management (N₁- Full RDF through inorganic source (urea), N₂- 75% N through urea + rest N through FYM, N₃- 75% N through urea + rest N through vermi-compost and N₄- 75% N through urea + rest N through mustard oilcake) in the sub plot. Results revealed that maximum vegetative growth in terms of plant height (99.4 cm and 57.8 cm), leaf area index (4.20 and 1.94), root length (11.60 cm and 15.50 cm) and weight (7.42 g and 0.409 g), dry matter accumulation (246.87 g/m² and 308.09 g/m²) was recorded for both oat and lathyrus respectively, when 75% N through urea + rest N through vermi-compost was applied. Oat performed better under 3:3 intercropping system due to the advantage of biological nitrogen fixation while, sole lathyrus showed highest performance compared to their other cropping situations. Growth rates of oat and lathyrus were highest in combination of 3:3 intercropping system and sole lathyrus respectively, with 75% N through urea + rest N through vermi-compost.

Key words: Growth characters, Integrated Nutrient Management, Intercropping, Lathyrus, Oat

ORGANIC FARMING IN INDIA: RELEVANCE, RESISTANCE AND STRATEGIES FOR PROMOTION

SAIKAT MAJI¹, PRIYAJYOTY KAR² AND ARINDAM NAG³

^{1&2}*Dairy Extension Division, ICAR-NDRI, Karnal, Haryana, 132001, ³Department of Extension Education, Dr. Kalam Agricultural College, Kishanganj, Bihar, 855107*

Organic farming is rapidly gaining ground in both developed and developing countries to overcome the challenges arising from chemical fertilizer based farming. India is not an exception from this recent trend. On the other hand increasing consciousness about conservation of environment as well as health hazards associated with agrochemicals has changed the consumers' preference towards safe and hazard-free food which is also major factor that lead to the growing interest in alternate forms of agriculture in the world. Under Indian condition, rapid spread of organic farming is possible because of some key geographical, cultural and economic advantages like traditional nature of farming and indigenous technical knowledge and practices followed by Indian farmers etc. vast stretches of arable land, which are mainly rain-fed and where negligible amount of fertilizers and pesticides are being used and have low productivity, could be exploited as potential areas for organic agriculture. However, there are certain issues under Indian context that should be taken care of before we go for a large-scale conversion to organic agriculture. The most important issues are- can organic farming produces enough food for everybody? Is it possible to meet the nutrient requirements of crops entirely from organic sources? Are there any significant environmental benefits that accrue from organic farming? Is it economically feasible? Prevalence of small and marginal dairy farmers also poses many challenges for faster proliferation of organic farming along with some other shortcomings. Present article provide some insight into these aspects along with some potential strategies to overcome these weaknesses and threats.

HEAVY METAL CONTAMINATION AND HEALTH RISK IN VEGETABLE CROPS

SAJAL DEBBARMA* AND LALIT BHATT

Department Of Vegetable Science, College Of Agriculture, G. B. P. U. A. & T., Pantnagar, Uttarakhand

Vegetables being rich sources of essential nutrients and antioxidants are taken as a common diet by populations throughout the world. However, now a days vegetables grown in industrial areas are getting contaminated with heavy metals which disturbing biological and biochemical processes in the human body. Heavy metal refers to any metallic chemical element that has a relatively high density and is toxic or poisonous at low concentrations. Although heavy metals are naturally present in the soil but geologic and anthropogenic activities mainly increases the concentration of these elements to amounts that are harmful to plants, animals and human beings. Some of these activities include mining, smelting of metals, burning of fossil fuels, use of chemical fertilizers and pesticides in agriculture, production of batteries and other metal products in industries, sewage sludge and municipal waste disposal. Heavy metals bioavailability

to plants is strongly related to the concentration and specification of the element in the soil solution because this is from where the plants uptake the heavy metals. The excessive intake of heavy metals from the soil creates dual problems; first the harvested crops get contaminated, which in turn serve as a source of heavy metal in our diet, and secondly the crop yield declines due to the inhibition of metabolic processes. Based on metal accumulation in edible parts and whole plants, root vegetables such as radish and carrot recorded lower accumulation of almost all heavy metals except zinc (Zn) in radish root whereas, leafy vegetables namely spinach, amaranthus, mustard and fenugreek recorded higher accumulation of both essential and non-essential heavy metals. Consumption of vegetables grown in polluted sites can cause serious consequences on human health. Once entered, heavy metals are deposited in bone and fat tissues, overlapping noble minerals and slowly released into the body and can cause an array of diseases. Therefore, possible remediation measures such as growing of hyperaccumulator plants, use of nano technology, addition of organic matter and lime in soil etc should be adopted. There is a relevant necessity for regular assessment and monitoring of these heavy metals in urban grown vegetables especially in industrially polluted areas to ascertain the level of heavy metal contaminants. Besides emphasis should be given in selection of vegetables for cultivation on such contaminated soils depending on their metal uptake potential and their distribution to edible part.

EFFECT OF PLANT GROWTH REGULATORS ON FRUIT SET, YIELD EFFICIENCY, FRUIT SIZE AND RUSSET FORMATION IN APPLE CV. SCARLET SPUR II

SAJAN SHARMA*, N. SHARMA, D. P. SHARMA AND NEENA CHAUHAN

Department Of Fruit Science, Dr. Y. S. Parmar University Of Horticulture And Forestry, Nauni-solan, Himachal Pradesh (173230) India

The field experiment was conducted during 2017 and 2018 to study the effect of GA₄₊₇+BA and CPPU on fruit set, fruit retention, yield efficiency, fruit size and russet control in apple cv. Scarlet Spur II. Experimental trees were subjected to ten treatments viz., T₁: GA₄₊₇+BA at 1ppm (2 sprays: PF+ 10 days later), T₂: GA₄₊₇+BA at 1ppm (3 sprays: PF+ later at 10 days intervals), T₃: GA₄₊₇+BA at 2.5ppm (2 sprays), T₄: GA₄₊₇+BA at 2.5ppm (3 sprays), T₅: GA₄₊₇+BA at 5ppm (2 sprays), T₆: GA₄₊₇+BA at 5ppm (3 sprays), T₇: CPPU at 2.5ppm (single spray at PF), T₈: CPPU at 5ppm (spray at PF), T₉: CPPU at 10ppm (spray at PF), and T₁₀: control (no spray). Among different treatments, GA₄₊₇+BA at 5ppm when applied thrice was most effective in reducing the russet formation and increasing fruit shape index (L/D ratio). However, higher increase fruit set, fruit retention, yield efficiency, fruit diameter and fruit weight observed with the treatments of CPPU at 10ppm applied at petal fall stage. Therefore, multiple application of GA₄₊₇+BA at 5ppm seems to be useful for controlling russetting and improving the fruit shape whereas single application of CPPU at 10ppm was most effective for increasing yield efficiency and fruit weight in apple.

Keywords : Apple, Promalin, CPPU, Petal fall stage, Russetting

RECENT ADVANCES IN FRUIT CROP IMPROVEMENT THROUGH TRANSGENIC APPROACHES

SAJANAS.¹, PRASHANT KALAL¹ AND PARVATHI BENNURMATH²

¹Division of Fruit Crops and ²Division of Floriculture and Medicinal Crops, ICAR- Indian Institute of Horticultural Research, Bengaluru-560089

The world population is predicted to double in the next 50 years according to the world population prospects. Ensuring an adequate food supply is going to be a major challenge, therefore, genetically modified fruit crops may pave a way to meet these challenges in a number of possible paths. There are various ways where the genetic engineering can be employed in fruit crop improvement such as transferring pest and disease resistance from the wild relatives which are sexually not compatible, conferring herbicide tolerance where manual weeding is a difficult task in case of large scale cultivation (Cranberry), imparting abiotic stress tolerance (*Poncirus trifoliata* showed enhanced salt tolerance after transformed with *nptII*, *AhBADH* gene), production of edible vaccines and reduction of juvenile phase. Most commonly used methods for transformation are agrobacterium mediated transformation, microinjection, particle bombardment and electroporation. There are several reports where the genetic compositions of different fruit crops are modified to get the desired traits such as Papaya (PRSV coat protein), Banana (*Musa DHN1*), Grape (*DREB1*) and Apple (*MdTFL-1*). Recent advanced methods used for transformation are gene silencing and gene editing technologies. Gene silencing includes antisense RNA and RNA silencing where the expression of the gene is prevented by interfering with the translation machinery. Gene editing technologies include Zinc finger nucleases, TALENs and CRISPR or Cas 9 which mainly rely on the engineered endonucleases which cleave the DNA due to the presence of sequence specific DNA binding domains. As the fruit crops are perennial in nature, these transgenic tools can be used to overcome various hurdles in fruit crop improvement such as long juvenile phase, heterozygosity etc. Genetically-modified fruit crops in addition to other horticultural crops have the potential to solve many of the world's hunger and malnutrition problems, and to help protect and preserve the environment by increasing yield and reducing reliance upon chemical pesticides and herbicides.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

HEAT TOLERANCE IN WHEAT GERMPLASM LINES**SAMITA***Choudhary Charan Singh Haryana Agriculture University, Hisar, Haryana, India*

Wheat (*Triticum aestivum*) is the staple food of more than a third of global human population and account for almost 20% of the total calories and protein consumed by human worldwide, more than any single food source. Wheat production need to be increased 70% by 2050 to feed world population. India is the second largest producer of wheat after china. In India Wheat is gamble with temperature. Due to global warming the world has been facing linear trends of increasing maximum and minimum temperature per decades by 0.3 and 0.2°C respectively. Such increase in temperature induced by climate change is expected to reduce wheat production. High temperature reduces yield by 3-4% per °C rise in temperature. Accordingly decline in South Asia is expected to be 50% by 2050. Reduction in yield is associated with both chronically high temperature during early grain filling as well as during late reproductive stage including grain filling. A field experiment comprised of 64 germplasm line was conducted at wheat research station, department of genetics and plant breeding, CCS HAU, Hisar, Haryana during crop season 2017-18 under late sown condition. Average grain filling duration in heat tolerant genotype was 45 days under late sown less by 19.8% than timely sown during 2017-18 crop seasons. Grain filling duration varied from 28 to 38 days under late sown condition. However, significant negative correlation was obtained for GFD with GFR that indicated reduction in grain filling duration enhances the rate of grain filling. Estimate of genetic parameters revealed low GCV and PCV over the years for individual and HSI of traits GFD. While moderate to high GCV and PCV for most of the grain yield and its component trait and for its HIS indicated additive gene action suggesting improvement through selection. Selecting more heat-tolerant cultivars traditionally grown in warmer regions may reduce heat related losses under global warming.

Keywords: temperature & grain filling duration(GFD).

ENHANCING AGRICULTURE THROUGH AGRIBUSINESS MANAGEMENT**SANDEEPACHARYA¹, JEEBAN KUMAR BISWAL² AND DEBASIS JAYAPURIA³**

Centre for Agri-Management, Utkal University, Bhubaneswar, Computer Science, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar; Odisha, Dept. of Ag. Extension, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Agribusiness is the business of agricultural production. It includes crop production, seed supply, agrochemicals, farm machinery, distribution, processing, marketing and retailing of agricultural produce to ultimate consumers. Agribusiness is used simply as a carry all agriculture and business within the agriculture industry, referring to the range of activities and disciplines encompassed by modern food production. Agribusiness has evolved from agriculture and has become a vast and complex system that reaches for beyond the farm to include all those who are involved in bringing food and fiber to consumers. Agribusiness Management programmes for critical management and entrepreneurial competencies to agricultural graduates for enabling them to own and manage Agribusiness enterprises of global standards. Agribusiness managers have great opportunities in agriculture production, agricultural marketing, food processing, supply chain, dairying and retailing sector in national and Multinational Corporation. These MNCs are very interested to investment in industries like agrochemical, organic farming, cattle feed industry, horticultural based industries, poultry, plantation, agroforestry, and ayurvedic industry in order to exploit the potentials of market access in India. So, Agribusiness management is necessary for developing trained manpower, to create business opportunities, reduce poverty through employment generation and industrial growth for the true development of Indian agriculture.

Keywords: Agribusiness, consumers, employment.

POPULATION DYNAMICS OF *BAGRADA HILARIS* (BRUMEISTER) ON INDIAN MUSTARD UNDER SEMI ARID CONDITIONS**SANDEEP KUMAR AND VISHVENDRA**

Population dynamics study of *Bagrada hilaris* on RH 40 showed that the pest reached its peak population twice in the cropping season, once at the seedling stage, and another at the maturity stage on both early, and late sown crop. The maximum population on early sown crop was observed with its first, and second peak observed on 43th SW, and 14th SW, respectively. While in the late sown crop the peaks in the pest population were noticed on 54th SW, and 19th SW of 2016-17, and 2017-18. The pest population had significant positive correlation with maximum temperature, and sun shine hours on both early, and late sown crops. However, the correlation with minimum temperature was non-significantly positive in early sown crop compared to significant positive correlation in late sown crop. Morning, and evening relative humidity showed highly negative significant correlation with the pest population. Wind speed had a significant negative effect on painted bug population in crop sown early in the season while the effect was positive, and non-significant in late sown crop. All weather parameters contributed to *B. hilaris* population fluctuation to the extent of 55 to 61, and 42 to 79 per Cent.

Keywords: Bagrada hilaris, correlation, Indian mustard, population dynamics

INVESTIGATIONS ON MAJOR INSECT PESTS OF PEARL MILLET [*PENNISETUM GLAUCUM* (L.) R. BR.] IN SEMI-ARID REGION OF RAJASTHAN

¹SANDEEP KUMAR CHOUDHARY, ²SHARWAN LAL JAT, ³N.R. SUNDA AND ⁴ARJUN LAL CHOUDHARY

*1*Division of Entomology, Rajasthan Agricultural Research Institute (RARI), Durgapura, Jaipur, 2,3& 4, SKN Agricultural University, Jobner 303329, Jaipur, India

Investigations on "Survey of major insect pests of pearl millet in semi-arid region of Rajasthan" were conducted at Division of Entomology, RARI Durgapura during 2014 and 2015. The two years survey during Kharif 2014 and 2015 on insect-pests of pearl millet in Semi-arid Eastern Plain of Rajasthan revealed that nine insect species, viz., shoot fly, stem borer, white grub, termite, grey weevil, leaf roller, chaffer beetle, grasshopper and *Helicoverpa* larvae appeared on pearl millet. The incidence of shoot fly, stem borer and white grub was observed as major pests; however, the incidence of other pests was meagre.

Key words: Pearl millet, survey, insect pests, incidence

PRECISION AGRICULTURE: SUSTAINABLE AND INTENSIVE CROP PRODUCTION

SANDEEP KUMAR MAURYA

Department Of Agronomy, Institute Of Agricultural Sciences, Banaras Hindu University Varanasi- 221005, UP, India

Precision agriculture comprises a set of technologies that combines sensors, information systems, enhanced machinery, and informed management to optimize production by accounting for variability and uncertainties within agricultural systems. Precision agriculture provides a means to monitor the food production chain and manage both the quantity and quality of agricultural produce. By using site-specific knowledge, PA can target rates of fertilizer, seed and chemicals for soil and other Precision agriculture has generated a very high profile in the agricultural industry over the last decade of the second millennium but the fact of 'within-field spatial variability', has been known for centuries conditions. To improve the application of fertilizers by varying rates and blends as needed within fields. Socio-economical barriers are principally costs and lack of skills. Agronomical challenges are lack of basic information, inadequate sampling and scouting procedures, absence of site-specific fertilizer recommendations, misuse of information, and lack of qualified agronomic services. The doubling of agricultural food production during the past 35 years was associated with a 6.87-fold increase in nitrogen fertilization, a 3.48-fold increase in phosphorus fertilization, a 1.68-fold increase in the amount of irrigated cropland, and a 1.1-fold increase in land in cultivation. Based on a simple linear extension of past trends, the anticipated next doubling of global food production would be associated with approximately 3-fold increases in nitrogen and phosphorus fertilization rates, a doubling of the irrigated land area, and an 18% increase in cropland.

IDENTIFICATION OF TOXIC AND NON TOXIC LINES IN JATROPHA

SANDEEP KUMAR

Department of Plant Breeding and Genetics, Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur, India- 482004

Interspecific hybridization as prebreeding approach has been proved as an important approach to widen variability and potential plants emerged as derivatives have been effectively utilized in genetic improvement of Jatropha. The genetic approach proved applicable for utilizing nontoxic source applying conventional breeding and HPLC analysis of Phorbol 12-Myristate 13-Acetate (PMA) to develop nontoxic, high oil yielding lines for the commercial use. The research was conducted on plants comprising selected crosses involving non-toxic lines, old crosses and backcrosses with and without nontoxic parents in early and late flowering, advanced lines and its clones on quantitative and qualitative traits. Performance of plants among crosses under study revealed utilization of plants from different the crosses for plant height (52-5×61-3), branches and number of seed/plant (61-3×21-8, 61-3×? and 9-1×61-3×B1-11) capsule weight and seed index (GF×34-23×34-6) number of capsules (14-16×34-6) seed yield (21-8×52-2) and cross 13-17×small for hulling percentage. The cross JC13×NT-6, 9-1×61-3 and H1-6-2-4 are identified for increasing oil content. One plant of the cross (52-2×61-3) has been identified for more number of traits viz. Capsule yield, seed yield, seed index and high oil content (53.40%) followed by cross 21-8×52-2 have been identified for a high number of the capsule, seed yield, seed index and acceptable level of oil content (41.4% kernel basis). Most of the crosses exhibited more than 30% of oil content, capsule yield >51.259 g, seed yield > 516.25 g and seed index > 60.00g. The detailed analysis of PMA in seeds and its part precisely contributed in establishing the genetic basis (maternal inheritance) and also hypothesizing involvement of more than one dominant genes controlling PMA content in Jatropha.

EFFICACY OF DIFFERENT INSECTICIDES AND BIORATIONALS AGAINST MUSTARD APHID, LIPAPHIS ERYSIMI UNDER NATURAL CONDITION.**SANDEEP KUMAR AND VISHVENDRA**

A field experiment on mustard var. Pusa bold was conducted during Rabi season of year 2016-17 and 2017-18 at S.V.P.U. Of Ag. & T., Meerut. The observations were recorded at 3, 7 and 10 days after spraying of insecticides after each spray. Among the various insecticides evaluated against the mustard aphid, *Lipaphis erysimi* Kalt, thiamethoxam 25 WDG @ 100 g/ha showed minimum (28.67) number of aphids thiamethoxam 25 WDG @ 150 g/ha mustard aphid followed by imidacloprid 17.8 SL @ 150 m/ha (31.33) number of aphids at 3 days after second spray, respectively. Similarly same trend was noticed after 7 days of spraying in which both the chemicals registered 13.33 and 14.67 minimum number of aphids. The experiment was repeated after 15 days to check the aphid population and it was observed that thiamethoxam 25 WDG @ 100 g/ha was found best followed by imidacloprid 17.8 SL @ 150 m/ha and dimethoate 30 EC @ 1000 ml/ha, when the data was recorded after 7 and 15 DAS.

BIODYNAMICS FARMING FOR SUSTAINABLE AGRICULTURE**SANDEEPYADAV, DINESH K. SINGH, SMRITI SINGH, ASHISH K. SINGH, LAVLESH**

Department of Vegetable Science, Govind Ballabh Pant University of Agriculture and Technology, Pantnagar (Udham Singh Nagar 263145), Uttarakhand, India.

India is one of the agricultural based nation with more than 58% of the population pertaining to agricultural sector. Before 1960, in India only organic farming practice was followed without chemical fertilizers and pesticides. During late 1960s, there was threaten to food security due to population raise and frequent draughts. Government of India had entered collaboration with USA for reforming farming practices by adding chemical products for cultivation, diseases and weed management. The introduction of a reckless chemical in the recent decades has adverse impact on the Indian agricultural practices and serious environmental concerns have been raised. All these factors completely come against the sustainable agriculture. To escape from the harmful effects of chemicals, the concept of organic farming was emerged. In organic production system biodynamics farming is a good source for sustainable agriculture. Biodynamic Agriculture is an advanced organic farming system that is gaining increased attention for its emphasis on food quality and soil health. Among the many tested models of agriculture, biodynamic agriculture has taken highest prominence in the development of international principles and standards. There is a wide body of knowledge and scientific research proving the soundness of biodynamic principles. The goal of a Biodynamic farming is to be able to support just the right balance of people, plants and animals. In the organic production system, in general, micronutrients are not taken care, there is every doubt that over long duration, there deficiencies may create production constraints and these technologies might be a failure rather than a sustainable alternative. Biodynamics agriculture, under the present scenario appears to be sound alternative.

KEY ROLE OF SOIL HEALTH IN AGRICULTURAL PRODUCTION**SANDEEP BEDWAL¹, ANKUSH¹, VIKRAM SINGH² AND D.S. JAKHAR¹**

¹Department of Soil Science and ²Department of Agronomy

Soil is an important component of terrestrial ecosystems that supports life on the earth. A healthy soil is fundamental for sustained agricultural productivity and environmental resiliency. Feed the soil to feed the plant is the basic principle for better health of soil. Soil health is an integrative property that reflects the capacity of soil to respond to agricultural intervention but with the increasing and juxtaposed challenges of population growth, the pressures of constantly increasing production have resulted in a persistent decline in soil fertility which is a major challenge that Indian agriculture is facing. It resulted in overuse of chemical fertilizers, excessive tillage, jettisoning of age-old organic soil revival practices and lack of appropriate crop rotation which leads to soil degradation and loss of fertility. Soil flora-fauna plays a critical role in maintaining soil health, ecosystem functioning and productivity. Decline in soil organic matter causes limited soil life and poor soil structure. Managing for soil health is mostly a matter of maintaining suitable habitat for the myriad of creatures that comprise the soil food web. This can be accomplished by disturbing the soil as little as possible, growing as many different species of plants as practical, keeping living plants in the soil as often as possible, and keeping the soil covered all the time.

RESPONSE OF ORGANIC MANURE ON GREEN GRAM (*PHASEOLUS RADIATA* L.) UNDER RAIN-FED CONDITION OF CHITRAKOOT***SANDEEP MOHBE *C.K. DOTANIYA, R.K. DOUTANIYA**

*Department of Agronomy, OPJS University Churu -331303, *ICAR-Indian Institute of Soil Science Bhopal M.P. 462038*

The field experiment was carried out during kharif season under semi arid climatic zone situated at 21°06' to 26°30' north latitude and 82°48' longitude 2014 at rajaula instructional farm to evaluate the appropriate dose of suitable organic matters used on green gram under rain-fed condition. Nine different organic matter (FYM, Vermicompost, Goat Manure and Poultry Manure) treatments along with one

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

control were tested in Randomized Block Design with three replications. After analysis of data shifted in various table results revealed that poultry manure (T_8) showed, best performance in initial plant height at 15 DAS, pod formation 8.0 and 17.53 at 45 and 60 DAS respectively, Highest nodule formation at 60 DAS 27.27, maximum yield per plant 9.31 gram and maximum seed yield per plot 1368 gm. In this experiment it can be concluded that treatment T_8 with Poultry manure increased the yield with maximum formation of nodule on plants of green gram.

NUTRIENT RETURN UNDER DIFFERENT SPACING OF *EUCALYPTUS TERETICORNIS* BASED AGROFORESTRY SYSTEM

SANGAM BADESHRA, K.K. BHARDWAJ AND SONIA DEVI*

Department of Soil Science, CCS HAU, Hisar

The present study was conducted at Research Farm, Department of Forestry CCS HAU, Hisar to assess the effect of *Eucalyptus tereticornis* spacings on litter production, nutrient content and nutrient addition. The maximum leaf litter production was found at 3×3 m followed by 6×1.5 m and 17×1×1 m spacing. Nitrogen, phosphorus and potassium were ranged from 1.09 to 1.14, 0.14 to 0.16 and 0.18 to 0.21%, respectively. The *Eucalyptus* planted at 3×3 m spacing produced the highest amount of N, P, K, Ca and Mg through leaf litter as compared to wider spacing. The nutrient addition through leaf litter of *Eucalyptus* differed significantly to each other. As the distance increased the nutrient addition decreased significantly and it was found minimum at 17×1×1 m spacing. The close spacing of *Eucalyptus* returned substantial amount of N (107.4 kg/ha/year) while the average annual input of N, P and K were 95.6, 12.9 and 17.6 kg/ha/year, respectively. The input of Ca and Mg ranged from 96.8 (17×1×1m) to 122.9 (3×3 m) and from 50.4 (17×1×1m) to 63.3 (3×3 m) kg/ha/year, respectively. The amount of micronutrients returned through annual litter fall in different spacing of *Eucalyptus*-based agroforestry system differed significantly. The total mean micronutrients (Zn, Mn, Cu and Fe) return through leaf litter was 6.0 kg/ha/year out of which maximum contribution was of Mn (45%). Thus close spacing of *Eucalyptus tereticornis* based agroforestry system produced highest litterfall which also resulted into more nutrient addition to the soil.

Keywords: Eucalyptus, agroforestry, litterfall, spacing and nutrient return

NANOTECHNOLOGY- INNOVATIVE APPROACH IN AGRICULTURE

Sangbuanliu Gonmei-Student, Girish Tiwari-Assistant Professor, Department of Agriculture, SGRRITS, SGRRU, Dehradun, Uttarakhand-248001.

Agriculture is an area where new technologies are often applied to improve the yield of crops. Nano agriculture involves the employment of nano particles in agriculture. Nano technology has been extensively used in food production, plant protection, processing, packaging, transportation of agricultural products and quality control and environmental management. It has great potential to make agriculture more efficient by using nano sensors and nano agricultural chemical. Nano biotechnology is advancing towards the ability to sequence DNA in nano fabricated gel-free systems, which would allow for significantly more DNA sequencing of crop germ plasm can potentially provide highly useful information about molecular markers associated with agronomically and economically important traits. Thus, nano biotechnology can enhance the pace of progress in molecular marker assisted breeding for crop improvement. Also nano particles are materials that small enough to fall within the nano metric range with at least one of their dimension being less than a few hundred nano meters. These materials would release pesticides and fertilizers at a specific time and targeted location. Nano particles tagged to agro chemicals or other substances could reduce the damage to other plant tissues and the amount of chemicals release to the environment. With the current application and advancements soon to come, nano technology will have a great impact on the direction that agriculture will take.

DEVELOPMENT OF INSECT RESISTANCE PLANT VARIETIES BY PLANT BREEDING TECHNIQUE

SANGEETA TIWARI*¹, NEHA DAHIYA² AND RASHMI²

Department of Entomology, CCS HAU; Hisar Haryana- 125004, India. Department of Genetics and Plant Breeding, College of Agriculture, G. B. Pant University of Agriculture and Technology, Pantnagar, Uttarakhand-263145

Insect are major biotic factor which cause significant losses in various crops. The insecticides are used by farmers for their management but over use of chemical insecticides results in many problems such as development of insecticide resistance, reduction in population of natural enemies, resurgence, environmental pollution, human health hazards etc. All these problems can overcome by development of Insect resistance plant varieties. The basic mechanism of resistance are non-preference, antibiosis and tolerance. The resistance can be due to morphology, physiological, biochemical and genetical factors of plants. The genetic factors are mainly of three type monogenic, oligogenic and polygenic. For development of resistant plant varieties breeder should know the major sources of resistance. The main sources of resistance found in nature are cultivated varieties, wild species, germplasm collections, mutations and introduction of

microorganism. The method of breeding to develop insect resistant plants are introduction, selection and hybridization. The field screening is done before released of varieties for commercial purpose. This technology of insect pest management is found to be associated with following advantages like compatible to all other management techniques, much cheaper as compared insecticides and it is the simplest seed based technology do not need any extra skill for application.

MECHANIZED RICE CULTIVATION PROBLEMS AND PROSPECTS

SANJANA. G¹, SURESH KUMAR. B² AND SALOMI GRACE. M³

Acharya N.G. Ranga Agricultural University, Agricultural College, Naira 532 185, Srikakulam (Dist.)

Asian countries are occupying 89% of world total rice area producing 90% of total rice production. Mechanization saves time in completing different operations with increasing precision and production, reducing drudgery and cost of cultivation. Laser land leveler smoothers land surface, enhanced rice-wheat system productivity by 10 per cent and saving of water by 22 per cent, increases water productivity from 0.55 to 0.91 kg grain m⁻¹ (Naresh *et al.*, 2011). Three percent higher grain yield (40.35 q ha⁻¹) using multi crop seed cum ferti drill compared to traditional method of crop establishment (Tarun K.M, 2006). Drum seeder reduces *cost of cultivation* by 11,708 ha⁻¹, *increases net income* by 14,673 ha⁻¹ and *yield* by 243 kg ha⁻¹, labour and time saving of 90 per cent and 75 per cent *respectively over conventional method of transplanting* (Senthikumar *et al.*, 2010). The paddy transplanter saves seed quantity by 21 kg ha⁻¹, labour of 40 per cent, net returns increased by Rs.7664 ha⁻¹ and grain yield was increased by 0.87 t/ha over traditional transplanter (Sing, R.S and Rao, K.V.R.). Cono weeder increases weed control efficiency up to 85.5 per cent over manual weeding (Anantachar *et al.*, 2016). Combined harvester saves average time, cost and grain over manual methods by 97.5 per cent, 35 per cent and 2.75 per cent, respectively (Hossain *et al.*, 2015). Hold on type paddy pedal thresher showed 96.7 per cent threshing recovery, 98.8 per cent threshing efficiency and 90.7 per cent cleaning efficiency over traditional method of threshing (Weerasooriya *et al.*, 2011). Mechanization plays a very crucial role in agricultural sector, in rice cultivation.

Key words : Laser land leveler, Drum seeder, Paddy transplanter, Cono weeder, Combined harvester

MODE OF ZINC APPLICATION ON GROWTH AND BIOCHEMICAL CHANGES IN YIELD OF RICE

SANJAY KUMAR TRIPATHI¹, PRADIP KUMAR SAINI², R. K. YADAV², NIKITA NEHAL² SHASHANK SRIVASTAV¹

¹Deptt. Of Plant Physiology, Chandrashekhar Azad University of Agriculture and Technology, Kanpur (U.P.), ²Deptt. Of Plant Physiology, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.)

The treatments include viz- Control, ZnSO₄ 15 kg ha⁻¹ (recommended), 2% ZnSO₄-foliar spray at 30 DAT, 3% ZnSO₄-foliar spray at 30 DAT, 5% Zinc oxide- aqueous slurry, 4% Zinc oxide- aqueous slurry, 3% Zinc oxide - aqueous slurry. soil of the experimental field was salty loam in texture, poor in organic carbon and nitrogen, medium in available P (35 kg ha⁻¹) and potash (260 kg ha⁻¹). The observations were recorded 25, 50, 75 and at maturity stage of crop. Data regarding growth parameters as plant height (cm), tiller production hill⁻¹, dry biomass hill⁻¹, relative water content (%) and biochemical changes as chlorophyll (SPAD Value), and sodium and potassium uptake by leaves were taken. Yield and yield attributing parameters were also recorded at crop harvest as panicle length (cm), number of panicle hill⁻¹, number of grain hill⁻¹, grain yield plant (g), grain yield qha⁻¹, test weight (g) and harvest index (%). Statistically significant plant height (cm), tiller production hill⁻¹, dry biomass plant⁻¹, relative water content (%), chlorophyll content (SPAD Value), carbohydrate content (mg g⁻¹ dry weight) were recorded with 3% ZnSO₄ foliar sprayed at 25 DAT followed by 2% ZnSO₄ foliar sprayed at 25 DAT. Regarding sodium and potassium content by leaf there were no any influence of zinc application. Yield and yield attributing parameters such as panicle length (cm), number of panicle hill-1 number of grains hill-1, grain yield plant (g), grain yield qha-1, and harvest index (%). Were significantly recorded with 4% ZnSO₄ foliar sprayed followed by 3% ZnSO₄ foliar sprayed at 25 DAT, while 1000 grain weight was found non-significant.

“EFFECT OF INTEGRATED NUTRIENTS MANAGEMENT ON YIELD, QUALITY AND NUTRIENTS UPTAKE BY MUSTARD (BRASSICA JUNCEA L.)”

SANJAY KUMAR, K.G. YADAV AND PREM SIGH*

*Department of Agronomy, SVPUA&T, Modipuram, Meerut, U.P.-250110, *Department of Soil Science, SVPUA&T, Modipuram, Meerut, U.P.-250110*

A field experiment was conducted to study the effect of organic and inorganic sources of nutrients on yield, quality and nutrients uptake by mustard (*Brassica juncea* L.) variety Pusa Mustard 30 (LES-43) at Crop Research Centre Chirori, Meerut during rabi season, 2016-17. The soil of experimental field was sandy loam texture, alkaline in nature with pH (8.2), low in organic carbon (0.41%) and available nitrogen (180.50 kg ha⁻¹), available phosphorus (16.80 kg ha⁻¹), available potassium (231.47 kg ha⁻¹), available sulphur (7.38 kg ha⁻¹). Fourteen treatments of different nutrient management practices consisting (T₁) Control, (T₂) Bio-fertilizers (Azotobacter + PSB), (T₃)

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

100% RDF (120:60:60: 40, N:P:K:S,kg/ha), (T₄) 100% RDF + Bio-fertilizers, (T₅) 75% RDF + FYM 6 t/ha, (T₆) 75% RDF + FYM 6 t/ha + Bio-fertilizers, (T₇) 75% RDF + Vermicompost 2 t/ha, (T₈) 75% RDF + Vermicompost 2 t/ha + Bio-fertilizers, (T₉) 50% RDF + FYM 12 t/ha, (T₁₀) 50% RDF + FYM 12 t/ha + Bio-fertilizers, (T₁₁) 50% RDF + Vermicompost 4 t/ha, (T₁₂) 50% RDF + Vermicompost 4 t/ha + Bio-fertilizers, (T₁₃) 50% RDF+ FYM 6 t/ha + Vermicompost 2 t/ha and (T₁₄) 50% RDF+ FYM 6 t/ha + Vermicompost 2 t/ha+ bio-fertilizer were tested in randomized block design with three replication. The experimental results revealed that maximum growth parameters (plant height, branches plant⁻¹, dry matter accumulation and leaf area index), yield attributes (siliqua length, siliqua plant⁻¹, seeds siliqua⁻¹ and test weight), yield (grain and stover), nutrient uptake (N, P, K and S) by grain and stover and available soil nutrient (N, P, K and S), were recorded with application of 50% RDF+ FYM 6 t/ha + Vermicompost 2 t/ha+ bio-fertilizer higher than the rest of the treatments. The increment in seed yield with application of 50% RDF+ FYM 6 t/ha + Vermicompost 2 t/ha+ Bio-fertilizers was 168.35% over control. Maximum gross return, net return were recorded with the application of 50% RDF+ FYM 6 t/ha + Vermicompost 2 t/ha+ Bio-fertilizers, however B:C ratio was lower than the use of RDF only but in application of FYM and Vermicompost improved the physiochemical properties of soil which may improved the sustainability of production system.

OPTIMIZATION OF ENVIRONMENTAL FACTORS FOR PRODUCTION OF PLANT GROWTH REGULATORS BY *PSEUDOMONAS* AND *BACILLUS* SPECIES.

SANJEEV KUMAR VERMA¹, MOHINDER KAUR², SANJEEV RAVI³ AND VIJAY KUMAR⁴

^{1&2} Department of Basic Sciences and ⁴ Fruit Science Dr. YSP UHF Nauni Solan (HP) 173230, ^{1,3&4} Present address: College of Horticulture, VCSG UHF Bharsar Pauri Garhwal 246123 Uttarakhand, India.

Under the present study, an attempt was made to study production of bacterial plant growth regulators viz. auxins, gibberellins and cytokinins produced by indigenous strains of *Pseudomonas* and *Bacillus* species isolated from the rhizosphere of carnation and three medicinal plants viz., *Achryanthus aspera*, *Elaeagnus umbellata* and *Heracelum candicans* in the laboratory of Microbiology section in Department of Basic Science Dr YSP UHF Nauni, Solan H P. The effect of five factors viz. media, incubation period, temperature, pH, shake and stationary conditions were observed. The selected isolate preferred media for the growth and high production of plant growth regulators i.e. succinate media by both *Pseudomonas* strains for all the three growth regulators. Peptone water by both the *Bacillus* strains for production of auxins and cytokinins and *Bacillus* medium by *Bacillus* sp. for production of gibberellins. All the four bacterial strains produced maximum plant growth regulators at 72 h of incubation period at pH 7.0 under shake condition while the optimum temperature for the production of growth regulators was 30°C for both the *Pseudomonas* species and was 40°C for both the *Bacillus* sp. Two strains each of *Pseudomonas* and *Bacillus* species (*Pseudomonas* Mc, PS-II and *Bacillus* UF₂ and KN₆) were selected for further studies with the aim to find out the best indigenous plant growth regulators producing bacterial strains for application in field in order to increase yield and crop productivity and also to find out industrially important strains for the production of plant growth regulators.

VARIOUS ARTIFICIAL INOCULATION METHODS FOR DOWNY MILDEW AND WHITE RUST IN MUSTARD

SANJEEV RAVI* AND R.P. AWASTHI

Department of Plant Pathology, College of Agriculture, G.B.P.U.A. & T. Pantnagar-263145, Uttarakhand, India, *Present address: Department of Plant Pathology, College of Horticulture, VCSG UHF Bharsar Pauri Garhwal-246123, Uttarakhand, India.

Indian mustard [*Brassica juncea* (L.) Czern and Coss.] is an important oil seed crop. The major fungal diseases are white rust (WR) *Albugo candida* and downy mildew (DM) *Hyaloperonospora brassicae*. The experiment was conducted at Oil seed laboratory and Glass house-Plant Pathology, College of Agriculture, GBPUA&T Pantnagar. Infected staghead samples were collected from *B. juncea* cv Varuna at NEB-CRC, Pantnagar. Suitable methods of inoculation for test pathogen, inoculation materials were prepared alone: seed, soil and spray; combination seed+ soil, soil+spray, seed+spray including check. Per cent disease index (PDI) was calculated (0-9) rating scale. PDI (Downy mildew): For (DM) in combination soil+spray treatment was most effective, given highest per cent disease index (48.33 %) and followed by seed +spray (43.67 %) and lower in alone, Seed (27.67 %). PDI (White rust): For (WR) disease index was highest in case of soil+spray (57.67 %) at 21 DAI (Days after inoculation) and followed by seed+spray (51.67 %) at 21 DAI and seed + soil (48.33 %) at 21 DAI. In case of soil+spray (44.67 %) at 14 DAI, followed by seed+spray (39.33 %) and seed + soil (35.33%) treatments. It was found that combination of treatments were effective at both 14&21 DAI. Incubation period (IP): Observed (IP) was most effective in case of combination soil+ spray treatment for both DM and WR. Alone: Spray treatment incubation period is most effective and followed by soil and seed treatment. (WR) pustule size: At 14 DAI, observed the pustule size small (S: 0.5-1.0 mm) in alone treatments viz., seed, soil and spray; medium in soil+spray, seed+spray and seed+soil mixed treatments. At 21 DAI, the pustule size went to medium (M: 1-3mm) in seed, soil and spray treatments and became large (L: 3-4mm) in case of mixed treatments viz., soil+spray, seed +spray and seed+soil indicating them as effective treatments to increase disease indices.

EVALUATION OF GROWTH AND YIELD COMPONENTS OF *BRASSICA JUNCEA* (L.) IN TARAI REGION OF UTTARAKHAND**SANJEEV RAVI* AND R.P. AWASTHI**

*Department of Plant Pathology, College of Agriculture, G.B.P.U.A. & T. Pantnagar-263145 Uttarakhand, India., *Present address: Department of Plant Pathology, College of Horticulture, VCSG UHF Bharsar Pauri Garhwal 246123 Uttarakhand, India.*

Indian mustard [*Brassica juncea* (L.) Czern and Coss.] is an important oil seed crop. Popularly known as rai, raya or laha is one of the most important oil seed crops of the country. Evaluation of eight genotypes of (*B. juncea*) were selected and measured under different parameters, unprotected field condition at NEB-Crop Research Centre GBPUA&T, Pantnagar. Plant height: was observed maximum in EC-399301 (182.67cm) and lower in Divya (105.00 cm), both of the year. Racemes length: It was maximum recorded in Kranti (51.67 cm) and lower in EC-399302 (33.33cm), in second cropping season observed maximum in Divya and lower in EC-399296. Primary branches: Observed in Varuna (7.33), Kranti (6.67) and EC-399302(6.33) and lower in Divya (4.33). In next year more in EC-399313 and lower in Divya. Secondary branches: More in Varuna (9.33) and lower in EC-399299 (4.67). In next cropping season found that maximum in EC-399301 and minimum in EC-399313 and Varuna. Total number of pods per plant: Pods were found maximum in Kranti (188.00) and minimum in EC-399302 (147.33). In next year more in Divya and minimum number in EC-399302. Number of pods on main raceme: Maximum number of pods on main raceme in EC-399301(41.67) and significantly lower in Divya (23.33). In second cropping season more number of pods on main raceme, EC-399301 and minimum number in Varuna. Yield per plot: Yield was observed significantly higher in EC-399301 (870.00 gm) and followed by EC-399296 (786.67gm) and significantly lower in Divya (443.33gm). In next year observed high yield in EC-399301 and significantly lower in Kranti, Varuna and Divya. Yield per hectare was calculated on the basis of per plot yield. 1000 -seed weight: It was observed that seed weight maximum in Varuna and minimum in Divya. In next season, revealed that maximum in Kranti and minimum in Divya. It was found that both of the cropping season resistance genotypes EC-399301 and EC-399296 came out much yield per plot and then susceptible genotypes significantly lower yield was found in Divya and Varuna.

LIGHT TRAP USED IN INTEGRATED PEST MANAGEMENT AS MECHANICAL DEVICE IN RICE ECOSYSTEM**SANJU SINGH* AND AMIT KUMAR SHARMA**

Department of Entomology, Jawaharlal Nehru Agricultural University Jabalpur, Madhya Pradesh - 482004, India

The field experiment was conducted at Jawaharlal Nehru Agriculture University, Jabalpur (M.P) during *kharif* season 2016, and using light trap tool as mechanical method in rice ecosystem for integrated pest management. Light trap is one of the very effective mechanical methods of insect pest management in sustainable agriculture. Light traps are mainly used at night in the field to collect various phototactic diversity of insects like moths, Coleopteran beetles and other Hemipteran bugs etc. For the taxonomic documentation, the light trap was operated every night and collection was observed on the next day morning. Total insect fauna was observed and sorted out on the basis of 2 major categories of economic importance: - I) Harmful insects- as crop pests. II) Beneficial insects- as bio-control agents (Predators and parasites). An insect pest of paddy and predator & parasite was observed on daily basis. Taxonomic analysis revealed that these 40 insect pest species of belonging to 3 orders and 17 families recorded throughout the *kharif* season June to October (2016). Based on number of species collected order Lepidoptera 22 species of 8 families, Hemiptera 6 species of 5 families and biocontrol agents of order coleoptera 12 species of 4 families. In Madhya Pradesh, rice is cultivated on 1.76 million hectares with annual production of 3.00 million tones and productivity of 1807 kg ha⁻¹. Majority of the insects are positively phototrophic in nature and use of light traps for insect catches produces valuable data. The objective of this study was to identify phototactic harmful insect fauna using light trap tool in rice ecosystem and describe them on the basis of taxonomic and economic aspects.

KEYWORDS:- Light trap, Rice, Taxonomic, Phototactic, Mechanical method

EFFECT OF SUSTAINABLE PRODUCTION MODEL ON PEARLMILLET (*PENNISETUM GLAUCUM*) WHEAT (*TRITICUM AESTIVUM* L.) CROPPING SYSTEM IN NORTH WESTERN PLAINS ZONE.**SANT BAHADUR SINGH AND RAJ VIR SINGH**

Department of Agronomy, R.B.S. College, Bichpuri, Agra (U.P.) - 283105

The experiment was conducted at Agricultural Research Farm, R.B.S. College, Bichpuri (Agra) in the year 2014-15. There were four treatments i.e. T₁ - Recommended dose of NPK + Full package of practices (except weed control); T₂ - Recommended dose of NPK + Full package of practices + FYM; T₃ - Recommended dose of NPK + Full package of practices + Weed Control (Chemical/ Hand weeding); T₄ Soil test based fertilizer application + Full package of practices + nutrient deficiency, if any tested in Randomized Block Design. The maximum grain yield (29.10 q ha⁻¹) of pearl millet was obtained with T₂ (100% RDF-NPK + Full package of practices + FYM 10 t ha⁻¹), followed by T₄ (Soil test based fertilizer + Full package of practices + macro/micro nutrient deficiency, if any) and the minimum grain yield was recorded with T₁ (- Recommended dose of fertilizer NPK + Full package of practices without weed control). The response of

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

FYM application @ 10 t ha⁻¹ was appeared quite clear and along with the relevance of soil test based fertilizer recommendation, correcting marginal deficiency of Zinc and Sulphur. The wheat yield was obtained maximum (53.40 q ha⁻¹) with T₂ - (RDF NPK + full package of practices + FYM 10 t ha⁻¹), closely followed by T₄ (Soil test based fertilizer + full package of practices + Macro/Micro nutrients deficiency, if any) and the minimum grain yield was recorded with T₁ (RDF -NPK+ Full package of practices without weed control).

STUDY ON CROP-WEED COMPETITION IN DIFFERENT CROPPING SITUATIONS

SANTOSH KORAV¹, CHANDRAMOHAN REDDY², MAHANTESHAM³

College of Agriculture CCS Haryana Agricultural University, Hisar-125004, Haryana, India

A weed is important biological factor in crop production that cause yield reduction and it contributes around 45% of crop yield loss. Weed life cycle similar with crops and some weeds have same morphological character with crop plants and farmers difficult to identify it at early crop growth stage. So the main concern of this review is to know critical time for crop weed competition, effect of weeds on plant growth and development, physiological changes, yield performance weeds studies includes density, different weed floras and its dry matter accumulation, finally why and purpose of weeds compete with crops. Increasing initial weed competition period reduces crop germination and at later stage of crop growth reduces the growth and development parameters like plant height, dry matter accumulation, leaf area index, physiological parameters like CGR, RGR, NAR, Chlorophyll content, leaf thickness are reduces. Similarly, increasing weeds competition reduces crop yield drastically.

Key words: physiological, critical period, weed flora, dry matter, chlorophyll, competition, yield

INFLUENCE OF WEED DENSITY ON NUTRIENT UPTAKE OF GROUNDNUT IN MID HILLS OF NORTHEAST INDIA

SANTOSH KORAV¹, VISHRAM RAM², LALAI.PRAY³ AND PREMARADHYAN⁴,

College of Post Graduate Studies, Umiam 793103, Meghalaya, India

Groundnut is an important oilseed crop in India which grows almost all agro climatic situations of India. It supplies food, fodder and industrial raw materials. The ICGS-76 groundnut variety developed by ICRISAT, Hyderabad which is most suitable for rainfed situations due to mid season drought tolerance, photo insensitive and early duration in nature. Weeds are major problem in rainfed groundnut due to more water availability and which competes with crop to resources for their development and suppresses the crop growth. Here results are clearly showed that the highest weed density was observed in weeds up to 75 DAE treatment (385 m⁻²) at 75 DAE stage in *kharif*. While, at 60 DAE stage, weeds up to 60 DAE treatment gave higher weed density (501 m⁻²) in *rabi* season and highest weed density was observed in *rabi* as compare to *kharif*. Similarly, uptake of N, P, K and S from kernel (49.27, 11.67, 14.65 and 2.98 Kg/ha in *kharif*; 34.69, 8.58, 10.90 and 2.27 Kg/ha in *rabi*) and stover (75.93, 7.90, 76.18 and 6.42 Kg/ha in *kharif*; 71.80, 7.1, 70.46 and 6.42 Kg/ha in *rabi*) of crop was maximum in weed free check in both *kharif* and *rabi* season but, increasing the period of weeds competition with crop, reduces the crop uptake of Nitrogen, phosphorus, potassium and sulphur drastically.

Key words: Kernel, Stover, Compete, Density, Nutrients, Suppress.

RESPONSE OF INTEGRATED NUTRIENT MANAGEMENT IN FRENCH BEAN (*PHASEOLUS VULGARIS* L.) FOR GREEN PODS PRODUCTION UNDER LATE SOWN CONDITION

¹SANTOSH KUMAR, ²DR. R. K. DOHAREY, ³GIRISH GOYAL AND ⁴NIDHEE SACHAN

¹Department of Horticulture, ²Department of Agriculture Extension, ³Department of Agronomy, and ⁴Department of Food Science and Nutrition, ^{1,3}C. S. Azad University of agriculture & Technology, Kanpur; ²NDUA & TKumarganj, Faizabad, ⁴Jiwaji University, Gwalior

A field study was carried out at Vegetable Research Farm of C. S. Azad University of Agriculture and Technology, Kalyanpur, Kanpur *Rabi* during-2017, to assess the effect a field experiment was conducted in randomized block design with ten treatments and three replications. The field experiment consisted of 10 treatments viz. T₁ FYM @ 10 t ha⁻¹, T₂ Vermicompost @ 5 t ha⁻¹, T₃ Neem cake @ 2 t ha⁻¹, T₄ FYM @ 5 t ha⁻¹ + Neem cake @ 1 t ha⁻¹, T₅ Neem cake @ 1 t ha⁻¹ + Bio-fertilizer PSB @ 5 kg ha⁻¹, T₆ FYM @ 5 t ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹, T₇ FYM @ 5 t ha⁻¹ + Bio-fertilizer PSB @ 2.5 kg ha⁻¹, T₈ Half RDF of N, P, K @ 1 kg ha⁻¹ + FYM @ 2.5 t ha⁻¹, T₉ Half RDF of N, P, K @ 1 kg ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹ + Bio-fertilizer PSB @ 2.5 kg ha⁻¹, T₁₀ RDF of NPK kg ha⁻¹ through chemical fertilizers. The field observations (plant height, number of branches, dry weight of the plant, number of green pods per plant, length of per pods, number of grain per plant and green pods yield (q ha⁻¹)). Were recorded among the treatments. T₈, the present study finally it is concluded that application of Half RDF of N, P, K kg ha⁻¹ + Vermicompost @ 2.5 t ha⁻¹ + Bio-fertilizer PSB @ 2.5 kg ha⁻¹ could be recommended for higher production of French bean.

EFFECT OF NPK LEVEL AND BIOFERTILIZER ON QUALITY PARAMETER AND SEED YIELD OF LINSEED (*LINUM USITATISSIMUM* L.) VARIETIES UNDER IRRIGATED CONDITION**SANTOSH KUMAR¹, J.K.SINGH², VIVEK¹, N.S. RANA¹**¹Department of Agronomy, ¹Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut 250110, ²Department of Agronomy, IAS, BHU Varanasi 221 005, Uttar Pradesh

Oilseeds occupy an important position in the agricultural economy of India. Currently India's total oilseed production is expected to grow 6.4 per cent to 37 million tons in 2015-16. Strong market prices for oilseeds and yield improvements will likely increase oilseed crush and push total oil meal production to 17.8 million tons, an increase of 6 per cent in 2015-16. Growing international demand for animal feed is also expected to push Indian oil meal exports to 5.6 million tons. Edible vegetable oil production and consumption are expected to increase to 7.6 million tons and 18.6 million tons, respectively. As a result, imports will increase to reach almost 11 million tons annually. A field experiment was conducted at Banaras Hindu University, Varanasi with treatment combinations of three NPK levels (50-30-20; 75-45-40 and 100-60-60 kg NPK/ha) in main plots and three levels of biofertilizers [Azotobacter, phosphate solubilizing bacteria (PSB) and combination of the both] in sub plots replicated in the thrice under split plot design. Results revealed that growth parameters, yield attributes and seed and stover yields were significantly higher under medium level of fertility (75-45-40 kg NPK/ha) as compared to low and higher level of fertility. The magnitude of increase in seed yield under medium over low and high levels of fertility was 22.4 and 13%, respectively. The maximum oil content (40%) and total NPK removal was observed under 50-30-20 kg and 75-45-40 kg NPK/ha, respectively. The iodine value which indicates the degree of unsaturation was decreased with either of increasing levels of NPK from 50-30-20 to 100-60-60 kg/ha or dual inoculation of seed with Azotobacter and PSB. The interaction effect indicated that the maximum seed yield (1318 kg/ha) and net return (38.92x103 Rs/ha) were observed from 'Sweta' variety of linseed fertilized by 75-45-40 kg NPK/ha along with dual inoculation of seed with Azotobacter and PSB grown under irrigated condition.

Key Words: Biofertilizers, Linseed, NPK levels, Oil quality and Yields.

SANTOSH SHIVRAN¹, VINOD BHATESHWAR² AND RAJ KUMAR JAKHAR³**DEPARTMENT OF GENETICS & PLANT BREEDING, JAWAHARLAL NEHRU KRISHI VISHWA VIDYALAYA, JABALPUR- 482004 (M.P.) INDIA***Department of Animal Husbandry & Dairying, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005 (U.P.) India, Department of Horticulture, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi-221005 (U.P.) India*

Seed is a basic agricultural input and it is an embryo, embedded in the food storage tissue. Seed is also defined as a matured ovule which consists of an embryonic plant with storage of food and surrounded by a protective seed coat. Every farmer should be able to access healthy seeds which are genetically pure, with high seed vigour and good germination percentage. Timely availability of good quality seeds at reasonable price ensures good yield and profit to the farmers. The seeds play a vital role in agriculture and acts as a carrier of the genetic potential of varieties. Quality seed production which follows efficient certification procedures plays a major role in the increase of food production of our country. To ensure this, the Government has prescribed standards and has brought in seed production techniques, testing, certification and marketing procedures through the Seeds Act, 1966. In the current scenario, the demand for good quality certified seeds far exceeds the availability in the market. This manual provides details about production and procurement of good quality seeds.

Key Words: Seed, Seed Production and Seed certification

ADOPTION OF NEW TECHNOLOGIES FOR SUSTAINABLE AGRICULTURE**SANTOSHI KUMARI BALAGA¹ AND DR. DEEPAK KUMAR MOHANTY²***1: M S Swaminathan School of Agriculture, Centurion University, Paralakhemundi, Gajapati, Odisha, 2: Dept. of Ag. Engineering, Krishi Vigyan Kendra Mayurbhanj-II, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha*

Indian economy made many long strides towards its socio-economic progress and made substantial development in almost all the sectors of its economy during the last fifty years. However, the success was heavily dependent on the success of the primary sector i.e., agriculture. Agriculture is essential for inclusive development because it produces food as well as economic wealth for many of the world's poorest people that allows for improved livelihoods through better health care, education, infrastructure improvements and greater investment in environmentally sound practices. At the global level, the adoption of improved agricultural technology is now considered critical to the attainment of the Millennium Development Goal (MDG) of reducing extreme poverty and hunger. Agricultural new technologies are the factors of production which have undergone some form of amendment from their original state with the intent of enhancing their performance. Adoption of improved agricultural technologies has been associated with higher earnings and lower poverty. Therefore the adoption of improved technology, key to agricultural development or increased productivity, basically depends on farmers' decision.

Keywords: Adoption, new technology and decision.

WATER MANAGEMENT STUDIES OF BARLEY CROP CULTIVARS UNDER WARMING CLIMATE SCENARIOS

SANU KUMAR SAHA^{1*}, SINGH S P², KINGRA P K³

Department of Climate Change and Agricultural Meteorology, Punjab Agricultural University, Ludhiana- 141004, Punjab, INDIA

Moisture requirement of barley (*Hordeum vulgare* L.) during *rabi* 2016-17 for Ludhiana and Gurdaspur districts of Punjab were computed using FAO developed windows based decision support system namely CROPWAT (v. 8.0) involving various weather parameters. The experiment was laid out in split plot design with three replications comprising of three sowing environments D₁ (25th October), D₂ (10th November), D₃ (25th November); two varieties V₁ (DWRUB 52) & V₂ (PL 807) and three irrigation levels viz. I₁ (Recommended irrigation), I₂ (Skip at vegetative stage) and I₃ (Skip at anthesis stage). ET_o along with radiation use efficiency was also estimated for both the region and the value stayed higher for Ludhiana as compared to Gurdaspur. Ludhiana recorded ET_o and RUE 2.74 mm day⁻¹ and 14 MJ/m²/day respectively followed by Gurdaspur to the tune of 2.17 mm day⁻¹ & 12 MJ/m²/day respectively. With the existing temperature, average crop irrigation water requirement computed by CROPWAT using crop coefficient approach was found maximum for Ludhiana (299 mm/dec) than that of Gurdaspur district (173 mm/dec). Increase in temperature up to +2°C from the present state simulated the seasonal ET rate @ 2.85 mm day⁻¹ for Ludhiana and for Gurdaspur region, the value was found @ 2.24 mm day⁻¹. Similarly, seasonal irrigation water requirement was increased from 299.9 mm to 316.6 mm for Ludhiana and for Gurdaspur, the same increased from 173 mm to 185.3 mm with the enhancement of temperature up to +2 °C from the existing conditions. Percent departure of ET_o was also measured which stipulated that the irrigation requirement and ET of barley will be influenced significantly more in Ludhiana as compared to Gurdaspur region in the backdrop of prevailing climate change scenarios.

Keywords: CROPWAT, Barley, FAO, RUE, DSS, Irrigation water requirement.

ROLE OF BIOFERTILIZERS IN INCREASING NUTRITIONAL STATUS OF CEREALS

SANYOGITA¹ AND RUPANJALI²

Department of Agronomy, G.B. Pant University of Agriculture and Technology, Pantnagar-263145, U.S. Nagar, Uttarakhand, India

In 1960s, India was known to world as begging bowl but now has managed to achieve the status of food secured nation in the world. In present scenario, nutritional security is a buzz word which seeks attention particularly, nutritional status of cereals is a big concern as these are consumed around 52% by Indian population in their daily diet of Indian population. Nutrient deficient crops lead to malnutrition. According to WFS, about 45% of children deaths are associated with poor nutrition in 2012. Therefore, to minimize this problem the nutritional status of cereals needs to be improved. In this regard, biofortification may play a significant role, which aims to increase nutrient level in crops during plant growth. Use of biofertilizers is one of the potential management strategies to boost nutritional status of the cereals. The protein, starch and gluten content in wheat grains were found significantly higher in Super Granules of bio-fertilizer (SGBF) treated plots as compared to application of urea alone (Kumar *et al.*, 2014). Bio-fertilizer (*Azospirillum brasilense*) in combination with 50% NPK and 5 t FYM/ha recorded significantly higher NPK uptake in kodo millet than application of 100% inorganic fertilizers (Dwivedi *et al.*, 2016). Biofertilizers viz., *Azotobacter spp.*, *Azospirillum brasilense* in combination with 50% NPK managed to achieve higher β -carotene (precursor of vitamin A) and protein content as compared to 50%NPK alone (Behra *et al.*, 2009). Thus use of bio-fertilizers is one of the promising ways to biofortify the cereals. Integration of biofertilizers with half of recommended NPK along with organic manure is the best bet option for higher crop and nutritional productivity.

'BEEKEEPING: A SUSTAINABLE APPROACH IN AGRICULTURE'

SAPNATI WARI^{*1} & DR. PRAMOD MALL²

Department of Entomology, G.B. Pant University of Agriculture and Technology, Pantnagar-263145 (U.S. Nagar) Uttarakhand^{*1}, G.B.

Pant University of Agriculture and Technology, Pantnagar- 263145 (U.S. Nagar) Uttarakhand²

The potentiality of beekeeping is enormous in favor of agriculture based rural economy of India. Though, beekeeping is best known for the production of honey and other bee products like royal jelly, bee wax, propolis, bee pollen and bee venom, its contribution in crop production by ensuring the cross pollination is also incredible. It not only ensures the supplementary nutritional intake but also offers the supplementary income and employment to the rural farmers. It also plays an indispensable role in sustaining the biodiversity in forest ecosystem by the pollination of trees and other natural vegetation. Beekeeping have proved to be as 5th input for agriculture which regulates the efficacy of other four inputs i.e. land, labour, capital and management including seed, fertilizer, pesticides, water, machinery, etc. The cross pollination by honeybees increases average agricultural yield by 20 to 25%. A number of varieties of apples, pear, plum, peaches and cherries are known to be self sterile and benefitted by bee pollination. Besides, a potential increase in yield also occurs in many other crops like mustard, rai, toria, sarson, rapeseed, safflower, linseed, niger, sunflower, alfalfa, berseem, broad beans,

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

dwarf beans, kidney beans, runner beans, arahar, radish, cabbage and turnip due to the bee pollination. The sustainable development of agriculture has demanded the reorientation of the current status of crop production technologies and the bee pollination is a key constraint to the sustainability of contemporary agriculture. Thus the necessity of beekeeping, its expansion and development is requisite in the view of sustainable future.

DOUBLING THE FARMERS' INCOME THROUGH INTEGRATED FARMING SYSTEM

***SARAT SEKHAR BORA **KARISHMA BORAH,**

Department of Agronomy, Assam Agricultural University, Jorhat, Department of Horticulture, Assam Agricultural University, Jorhat.

Livelihood security, nutritional improvement, agricultural sustainability and environmental safety have been major concern of Indian agriculture in context of small-farm holders representing more than 86% of farm families. Past experience has clearly demonstrated that the income from cropping alone is hardly sufficient to sustain the farmers' needs. The integrated farming systems (IFS) approach is considered to be the most powerful tool to enhance the profitability of farming systems, especially for small and marginal farm-holders. It can be concluded that diversification of existing farming systems with changes, addition or improvement of crop and livestock components and inclusion of horticulture are essential to improve on-farm income of small holders with environmental restitution. Diversification of existing farming systems clearly demonstrated the advantages in terms of production increase and employment generation. IFS paves way for meeting with the household demands of balanced food, improved recycling of nutrients and water besides increasing the on-farm employment for family. Recycling and intermittent use of products and by-products within the system could save in cost to the extent of 45% and even more.

Key words; IFS, diversification, employment generation, profitability, nutrient recycling

“ROLE OF ON-LINE COMMUNICATION TECHNOLOGY IN AGRICULTURE DEVELOPMENT”

SARITA (RESEARCH SCHOLAR) COLLEGE OF HOME SCIENCE CSAUAT KANPUR

Ram Bharose College Of Agriculture Nduat Faizabad, Pratima Tiwari (research Scholar) College Of Home Science Csauat Kanpur

On-line Communication technology has been considered as a tool that can be used to achieve development goals in developing countries. These technologies may help to fight against disease, unemployment, poverty, agriculture and other development problems. Agriculture plays a huge role in the society and the economy of the country. Nowadays, new advanced technologies are used for agricultural development, such as satellites, the Internet, mobile phone and social media. On-line Communication Technology can be used to improve agricultural information and farming methods with transformational development. In India around 70% of population earns its livelihood from agriculture. Agriculture needs continuous diffusion of new technology to meet global food security, poverty reduction and environment sustainability. On-line Communication Technologies in agriculture have the potential to facilitate greater access to information that support knowledge sharing. They facilitate the creation, storage, retrieval, and dissemination of any relevant data, and information that may have been already been processed and adapted. On-line Communication Technology in agriculture is an emerging field focusing on the enhancement of agriculture development in India. They can provide accurate information for the farmers which facilitates better agriculture output. But in Indian still in growing stage and evolving as an emerging trend the benefit of On-line Communication Technology is yet to reach all the farmers. Perhaps technological innovation many farmers, especially who are share croppers are not getting proper information and service due to poor economic condition and social constraints. Other factors are illiteracy, language barriers and unwillingness to adopt the new technology. The way in which On-line Communication Technology projects access, assess, apply, and deliver content may increase the likelihood of On-line Communication Technology used by farmers and thus may become an important factor in a project success. To address the information needs of farmers, relevant content is a key component of On-line Communication Technology projects.

ITK FOR CONSERVATION IN AGRICULTURE

SARMISTHA TOSH¹ AND DEBASIS JAYAPURIA²

1: B.Sc. (Ag.) 2nd year, Gandhi Institute of Biological sciences, Berhampur University, Gunupur, Rayagada, Odisha, 2: Subject Matter Specialist, Dept. of Ag. Extension, Krishi Vigyan Kendra Mayurbhanj-I, Odisha University of Agriculture and Technology, Bhubaneswar, Odisha

Indigenous technical knowledge (ITK) is the local knowledge that people have gained through inheritance from their ancestors. It is a people derived science and represents people's creativity, innovations and skills. We have many indigenous techniques for conserving natural resources. These have been in practice for number of years as presented in the write up. Therefore there is a need to enmesh these practices along with conventional soil and water conservation measures for promoting sustainable development of agriculture. It may not be out of place to mention that some of these ITKs may need minor modifications in different watershed situations as well as socio-economic fabrics across the country. Inclusion of these ITKs would ensure sustainability of different eco-systems, befitting the man-

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

animal plant-land-water complex in each watershed. Indigenous technological knowledge pertains to various cultural norms, social roles or physical conditions. Many ITKs on in-situ soil and moisture conservation are not adopted everywhere throughout India because of constraints in adoption and unawareness of the effectiveness of such practices. The promotion of appropriate technology with indigenous knowledge base will be effective in the natural resource management programme for increasing their adaptability/acceptability and to bring down the dependence on cost intensive technologies and help conservation of natural resources in agriculture.

Keywords: ITK, sustainability, conservation.

TRANSFER OF AGRICULTURAL TECHNOLOGIES THROUGH RECENT EXTENSION COMMUNICATION TECHNIQUES FOR FARMER'S PROSPERITY

SARVESH KUMAR¹ AND RC SHARMA²

Scientists, JNKVV, Agricultural Science Centre-Harda (MP)-461331

The effective transformation of technologies is high need of the hour to save food which may helpful to feed the mounting population of country. Effective extension in agricultural development requires a change of extension approach as a sole strategy in achieving effective and competitive agricultural development. Extension, in the current faces challenges of tackling objectives like promoting environmentally sustainable agricultural practices and efficiently linking of farmers to local and international markets including non-farm employment and enterprise expansion pairing technology transfer with other services relating to both input and output markets. Extension should play the key role to transfer of technical knowledge among the different entities to improve the overall performance of the innovation system. The recent advances in ICT can be used effectively in extension education for transfer to technologies by using digital extension paradigm for transfer of technology. The technology transfer involves a toptown approach that delivers specific recommendations to farmers about the practices they should adopt by 1. Mobile access for audio interaction and messaging 2. Television (audio-video) 3. Interactive video chat through android mobile phones 4. Tele-conferencing 5. E-mail 6. Face book 7. Whatsapp 6. Computer etc. In the present scientific era the technology, which is profitable, demonstrable, compatible and its dissemination should be quick. The Internet and other forms of computer networking can be of much useful for exchange of markets and other kinds of technical information to ascertain the prosperity and profitability of the farmers.

Keywords: Extension paradigms, food security, Prosperity of farmers, transfer of technology

INTEGRATED FARMING SYSTEMS APPROACH PROVES BACKBONE FOR DOUBLING INCOME OF SMALL AND MARGINAL FARMERS

SARVESH KUMAR AND RC SHARMA

Scientists, Jawaharlal Nehru Krishi Vishwa Vidyalay, Agricultural Science Centre-Harda (MP) 461331

The integrated farming approach leads to sustainable agriculture to increase farm yield and managing resources in order to address all three critical aspects of sustainability like economic, environmental and social with multiple objectives of sustainability, food security, farmer security and poverty reduction. It involves use of outputs of one enterprise component as inputs for other related enterprises wherever feasible, for example, cattle dung mixed with crop residues and farm waste can be converted in to nutrient-rich vermi-compost. The salient features of IFS include innovation in farming for maximizing production through optimal use of local resources, effective recycling of farm waste for productive purposes, community-led local systems for water conservation, organic farming, and developing a judicious mix of income-generating activities such as dairy, poultry, fishery, goat-rearing, vermin-composting and others. Presently small and marginal farmers struggling for better economic progress from small piece of land which is quite difficult without making agriculture high tech and full of innovations which is again not be possible without investing good amount of money. And with this farmers should also get remunerative price of their produce then only agriculture may be profitable venture. But now economic boost of farmers may be possible by using multidimensional approach in agriculture. The integrated farming approach may play very crucial role in economic growth of farmers in general and for small and marginal farmers especially because this system provides farmers a platform to get income from many ventures at time, so income multiplication become possible by adopting agriculture with animal production as well simultaneously covering, dairy, poultry, goatry etc. The small enterprises also can be established with less investment. The Integrated Farming Systems /approach may be more suitable for small and marginal farmers for their economic upliftment.

Keywords : Animal production, Economic growth, Integrated Farming System, small and marginal farmers.

WATER FOOTPRINT FOR SUSTAINABLE AGRICULTURE

SATINDER KAUR

Punjab Agricultural University, Ludhiana

Human activities consume and pollute a lot of water. At a global scale, most of the water use occurs in agricultural production, but there

are also substantial water volumes consumed and polluted in the industrial and domestic sectors. Water consumption and pollution can be associated with specific activities, such as irrigation, bathing, washing, cleaning, cooling and processing. Freshwater resources are becoming scarcer due to an increase in population and subsequent increase in water appropriation and deterioration of water quality. The impact of consumption of people on the global water resources can be mapped with the concept of the 'water footprint'. The water footprint of a nation has been defined as the total volume of freshwater that is used to produce the goods and services consumed by the inhabitants of the nation. It deviates from earlier indicators of water use in the fact that the water footprint shows water demand related to consumption within a nation, while the earlier indicators (e.g. total water withdrawal for the various sectors of economy) show water demand in relation to production within a nation. The water footprint is an indicator of freshwater use that looks not only at direct water use of a consumer or producer, but also at the indirect water use. The water footprint can be regarded as a comprehensive indicator of freshwater resources appropriation, next to the traditional and restricted measure of water withdrawal. The water footprint of a product is the volume of freshwater used to produce the product, measured over the full supply chain. It is a multidimensional indicator, showing water consumption volumes by source and polluted volumes by type of pollution; all components of a total water footprint are specified geographically and temporally. The water footprint thus offers a better and wider perspective on how a consumer or producer relates to the use of freshwater systems. It is a volumetric measure of water consumption and pollution. It is *not* a measure of the severity of the local environmental impact of water consumption and pollution. The local environmental impact of a certain amount of water consumption and pollution depends on the vulnerability of the local water system and the number of water consumers and polluters that make use of the same system. Water footprint accounts give spatiotemporally explicit information regarding how water is appropriated for various human purposes. They can feed the discussion about sustainable and equitable water use and allocation and also form a good basis for a local assessment of environmental, social and economic impacts.

PRODUCTION PERFORMANCE OF POULTRY GENOTYPES UNDER TRADITIONAL SYSTEM OF REARING IN KONKAN REGION OF MAHARASHTRA

SATISH JADHAO¹, A.J. MAYEKAR¹, SHALU KUMAR^{1*}, B.G. DESAI¹, J.S. DHEKALE² AND N.N. PRASADE¹

¹Department of Animal Husbandry and Dairy Science, Dr. B. S. Konkan Krishi Vidyapeeth (Agricultural University), Dapoli, Dist. Ratnagiri, Maharashtra, INDIA, ²Department of Agricultural Economics and Statistics, Dr. B. S. Konkan Krishi Vidyapeeth (Agricultural University), Dapoli, Dist. Ratnagiri, Maharashtra INDIA

The present experiment was conducted at Poultry Unit, Department of Animal Husbandry and Dairy Science, Dr. B. S. Konkan Krishi Vidyapeeth Dapoli, Maharashtra to assess the comparative growth performance and feed efficiency of poultry genotypes. The experiment was carried out on four different types of poultry genotypes viz., - Kadaknath (T₁), Vanaraja (T₂), Giriraja (T₃) and Rhode Island Red (T₄). For this experiment, 200 one day old chicks were divided in five replications and each replicate have 10 birds. Results showed that Giriraja birds gain significantly higher daily body weight gain, weekly body weight gain and total body weight gain with superior feed conversion efficiency compared to Vanaraja, Kadaknath and Rhode Island Red. The benefit cost ratio (B: C ratio) higher achieved by Kadaknath birds. From the results of present investigation, it can be suggested that the rearing of Kadaknath as well as Giriraja poultry birds are more beneficial and efficient than Vanaraja and RIR in Konkan Agro-climatic condition of Maharashtra.

Key words: Feed efficiency, growth rate, poultry breeds, weight gain, net profit.

NOVEL FUNGICIDE AND THEIR MODE OF ACTION AGAINST THE PLANT DISEASES

SATPAL SINGH, GOPAL SINGH, AJAY KUMAR MISHRA

Department of Plant Pathology, SVPUA&T, Meerut, UP, India.

Fungicides continue to be essential for the effective control of plant diseases. New classes of fungicides with novel modes of action are being developed since 1990s. These include the strobilurins, phenylpyrroles, anilinopyrimidines, and compounds that trigger defense mechanisms in the plant. *In vivo* glasshouse screens and field trials are expected to remain the dominant methods for characterizing new compounds. Low toxicity to humans and wildlife, low environmental impact, low residues in food, and compatibility with integrated disease management (IDM) programs are increasingly important considerations in the selection of fungicides for development. Classification of Fungicides on the basis of mode of action, general uses, chemical composition and generation of fungicides like first generation of fungicides (1800-1940), Second generation of fungicides (1940 - 1967), third generation fungicides (1970- 1996) and fourth generation fungicides (1996 onwards). Fourth generation fungicides are referred as novel fungicides. On the basis of mode of action, fungicides are divided into Single-site Inhibition fungicides like which effects on specific single target site like inhibition of synthesis of lipids, sterol, and other membrane components, amino acids and protein synthesis, respiration, mitosis and cell division, nucleic acids biosynthesis and multi site inhibition fungicides, those fungicides acts on multi sites of Fungus. Study about the biochemical mode of action of fluopicolide, new fungicides like metrafenone, famoxadone, spiroxamine, reliant and strobilurin fungicides and their respective novel mode of actions, we will also be dealt with and elaborated in the changing scenario of agriculture,

these novel chemicals needs to be popularized at mass scale.

PROFITABILITY OF MUSTARD THROUGH FRONT LINE DEMONSTRATIONS

DR. SATYA PRAKASH, PROFESSOR (HORTI.) & HEAD, DR. MAHAVIR SINGH, DR. P.K.MADKE, DR. DEVENDRA PAL

Krishi Vigyan Kendra, Ghaziabad & Saharanpur (UP), Sardar Vallabhbhai Patel Univ. of Agriculture. & Technology. Meerut U.P.

Cluster front line demonstrations (14 at Balia khedi & 16 block Rampur Maniharan) on the farmers field were conducted on complete recommendation package of practices in comparison up to farmers practice during Rabi 2017 on Mustard Crop in two Block of Saharanpur District of Western Uttar Pradesh. On the basis of two blocks average result indicated that higher seed yield 26.8qtl/ha Net monetary return Rs.83360/ha & B.C. Ratio 4.5 of Mustard variety RH-749 was obtained under recommended package of practiced which was 37.36% higher seed yield as compare to farmers practices. Farmers practice obtain 18.2qtl/ha Mustard yield variety PM 26.0 Net monetary return Rs. 51500 & B.C. Ratio 3.2 of Mustard only.

REGULATORY ROLE OF MINERAL ELEMENTS

SATYAJYOTI THONGBAM¹ ABHISHEK ANEJA¹ LEITAM NEKHANPRIYA²

¹*Department of Agronomy, ²Department of Horticulture, School of Agriculture, Lovely Professional University, Phagwara-144411*

Various mineral ions are recognized as vital plant nutrients that are directly incorporated into organic compounds synthesized by the plant. Out of these, potassium, phosphorus, calcium, magnesium and sodium are the most important quantitatively and are recommended for composition analysis (Anonymous 2004b). Minerals are inorganic nutrients, usually required in small amounts from less than 1 to 2500 mg per day. Vitamins and other essential food nutrients, mineral requirements varies with animal species. For example, humans and other vertebrates need large amounts of calcium for construction and maintenance of bone and normal functioning of nerves and muscles. Phosphorus is an important constituent of adenosine triphosphate (ATP) and nucleic acid and is also essential for acid-base balance, bone and tooth formation. Minerals have a diversified role in plant metabolism. Severity or scarcity of these causes miscellaneous effects in plant metabolism. Each and every aspect of plant biochemistry, physiology, anatomy, etc. is affected due to mineral nutrient composition of soils. The concentration of these minerals of both group i.e. activators or inhibitors present in the soil play a vital role in secondary plant metabolism. Minerals also play a major role in the reproduction in plants. Bioactive molecules of medical relevancy such as alkaloids, flavonoids, lignin's, lipids, carbohydrates, resins, glycosides, phenolic compounds, volatile oils, vitamins, tannins etc. produced through various biosynthetic pathways of plants are a boon to urban, hilly and remote population of each nation.

Keywords: Aadenosine triphosphate, Bioactive molecules, Biosynthetic pathways

THE ROLE OF INFORMATION TECHNOLOGY IN PRECISION FARMING

SAURABH CHANDRA¹, O.P. MISHRA², AND PRAMOD KUMAR PRAJAPATI³

³*Department of Extension Education, Institute of Agricultural Sciences, B.H.U, Varanasi, 221005.*

Agriculture is the backbone of India having 2.4% of total geographical area and supports 17.5% of world population and over 30% of world small holder's farmers and 4% of world's water resources. India is second largest arable land after the USA. The arable land per capita availability is 0.12 ha. The land is decreasing day by day and population is increasing day by day. The total food grain production is 277.49 million tonnes (June, 2018). The food demand by 2050 is projected to almost double and realized in an environment-friendly sustainable manner from the shrinking land, water, and biodiversity resources. The sufficient availability of food is the biggest challenges of the country. The second green revolution or sustainable green revolution is possible through the use of e-Agriculture. "The e-Agriculture defined as the dissemination of agricultural technologies at the right time to the right people living in dispersed geographical area". The precision farming is the one of the most emerging concept in India. It has the huge potential in Indian agriculture to transforming from conventional farming to modern agriculture. The e-Agriculture is provides the appropriate information of farmer so that the farmer can understand use and the importance of e-Agriculture. It provides the better utilization of input such as land, Labours, capital, management and 5th is information technology. Information technology is the branch of engineering that deals with the use of computer and Tele-communication to retains, store and transmit information."

Key words- Information Technology, e-Agriculture, Precision farming and drone technology.

APPLICATION OF GENE TAGGING IN CROP IMPROVEMENT**SAURABH SINGH¹, KUMARI SHIKHA^{2*}, VAIBHAV SINGH³ AND PRIYANKA JAISWAL⁴**^{1,3} *Horticulture*; ^{2,4} *Genetics and Plant Breeding, Banaras Hindu University*

Over the past few decades, progress has been made in an understanding plant genome. Gene tagging is one of the advance molecular approaches which refers to the identification of existing DNA by marking or tagging interrupted genes with a unique DNA sequence through insertional mutagenesis. This DNA sequence subsequently can be utilized as a target for hybridization or as an annealing site for PCR primers, allowing flanking sequences to be isolated. It is useful in assigning functions to the large quantity of sequence information, gene cloning and marker-assisted selection. This gene tag can be either T-DNA, transposons, molecular marker, epitope etc. In this article, we attempt to review most of the gene tagging methodologies and its application in crop improvement. These days, it is the most commonly used approach for selection of biotic and abiotic stress-resistant plants. It is more studying the genomics, metabolomics, transcriptomics and proteomics.

Keywords: Gene Tagging, Genomics Metabolomics, Transcriptomics and Proteomics

IMPORTANCE OF VERMICOMPOST AS A SOURCE OF ORGANIC MANURE**SAWAN KUMAR^{1*}, JOGINDER KUMAR² AND PRIYANKA³**^{1,2,3} *Department of Soil Science, CCS Haryana Agricultural University, Hisar, India-125004*

Vermicompost is the product of the composting process using various species of worm, white worms, and other earthworms, to create a mixture of decomposing vegetable or food waste, bedding materials, and vermicast. Vermicast (also called worm castings, worm humus, worm manure, or worm faeces) is the end-product of the breakdown of organic matter by earthworms. These castings have been shown to contain reduced levels of contaminants and a higher saturation of nutrients than the organic materials before vermicomposting. Vermicompost contains water-soluble nutrients and is an excellent, nutrient-rich organic fertilizer and soil conditioner. It is used in farming and small scale sustainable, organic farming. Vermicompost play an important role in improving growth and yield of different crops like vegetables, fruits and flowers. After using compost in most of the crops, it has been found that germination percentage as well as produce quality is very high. Apart from supplying nutrient and growth hormones to plants, vermicompost improves the soil structure leading to an increase in water and nutrient holding capacities. The commercial production of vermicompost is increasing at tremendous rate because of low production cost and high returns. In India, it costs about 4-5 rupees per kilogram and can be sold about 10-12 rupees per kilogram in open market. Moreover, it can be used in all types of crops.

Keywords: Vermicompost, Earthworm, Casting, Nutrient, Organic Farming

INFLUENCE OF NITROGEN LEVELS ON PRODUCTIVITY AND PROFITABILITY OF FINGER MILLET GENOTYPES**SIMAKUMARI, RAJNISHANAND AND C.S. SINGH***Birsa Agricultural University, Ranchi, Jharkhand 834006*

The experiment was conducted at Birsa Agricultural University Farm Ranchi, during kharif (rainy) season of 2009. The experiment was conducted in Randomized Block Design with three replications and twenty treatment combinations consisting of four nitrogen levels (0, 20, 40 and 60 kg N/ha) and five medium duration finger millet genotypes (TNAU-1022, OEB-219, KMR-204, RAU-8 and BM-2). Finger millet genotypes respond positively to nitrogen levels and application of 40 kg N/ha manifested significantly higher grain yield (20.71 q/ha) and straw yield (54.12 q/ha) of finger millet also improved significantly only upto 40 kg N/ha resulting is significantly higher net return (Rs.7235/ha) and Benefit: cost ratio (1.24). Among genotypes, BM-2 was found superior to rest of the genotypes except RAU-8 which was comparable to BM-2. Genotype BM-2 has outstanding performance in respect grain yield (19.54 q/ha) and straw yield (52.44 q/ha). The economics of result also revealed that BM-2 genotypes gave significantly higher net return (Rs.6816/ha) and benefit: cost ratio (1.20) than other genotypes except RAU-8.

PROCESS OPTIMISATION FOR FORMULATION OF PROTEIN RICH RECONSTITUTED RICE: VALORISATION OF RICE BY-PRODUCT**'SHAGHAF KAU KAB, S. K. JHA AND ABHIJIT KAR***Division of Food Science & Postharvest Technology, ICAR-IARI, New Delhi, India* ²*Principal Scientist, Division of Food Science & Postharvest, Technology, ICAR-IARI, New Delhi, India*

Food and nutritional security necessitated development of alternatives to staple foods. Rice provides 30 to 70 % of the calorific need of the country men and its processing produces 16-20 % of broken that has the potential to feed 290 million people. Therefore, with the objective to valorise these processing by-products and complementing it with protein and micronutrients, formulation of reconstituted rice was carried out. Rice was reconstituted using flours of cheaper ingredients viz. broken rice and soya in the proportion of 3:1.

2nd International Conference on "Advances in Agricultural, Biological and Applied Sciences for Sustainable Future (ABAS-2018)"

Extrusion process was adapted for protein, micronutrients and fibre rich reconstituted rice as non-agronomic and non-genetic method. Formulating reconstituted rice was optimized using central composite design and data were analyzed through response surface methodology. Objective of optimisation was to maximise bulk density, water uptake ratio and minimise cooking time, cooking loss, b value of colour and chewiness (none) at varying range of temperature, moisture content and screw speed. Reconstituted rice with high nutritional and sensorial characteristics was obtained at 67 to 68 °C barrel temperature, 19 to 22% (wb) feed moisture content and 45 to 49 % rated screw speed of the extruder. Optimised reconstituted rice was further evaluated for its sensory and cooking quality by functionalising it with binders and whitening agents like soy isolate, starch, guar gum, sodium alginate and CaCO₃ and their combinations. Friedman's non parametric test results suggested 1% soya isolate with 3% CaCO₃ as the most effective in improving overall quality of the product. This study suggested that reconstituted rice has immense commercial potential in meeting the modern day requirements off working population of instant nutritive products Thus, the product obtained could be used as the nutrition rich instant replacement for natural rice.

NUTRACEAUTICS IN FINGER MILLET - A BOON FOR HILL AGRICULTURE

SHAGUN GUPTA, CHHAYA SINGH, NEHA CHAUHAN AND VIBHUTI SINGH JHALA

Department of Agricultural Sciences, Shri Guru Ram Rai University, Dehradun, Uttarakhand

Finger millet (*Eleusine coracana* L.) is considered as a major field crop in hilly regions of North Western Himalayan regions which predominantly is grown as rainfed crop. It is advantageous for hilly farmer as it requires less water and care. Apart from this finger millet is remarkable in nutraceutical properties. It is rich source of phytochemicals, dietary fibres, polyphenols, vitamins and minerals and offer several health benefits to its consumers. Germinated finger millet can be a good substrate for statins (anti-hypocholesterolemic metabolites) production. Various in vitro and in vivo studies demonstrated its blood glucose lowering, cholesterol lowering and wound healing properties. It can be used for the preparation of dietetic foods for anaemia patients and geriatric food formulation. Several work demonstrated the antioxidant properties of millet. Finger millet also possesses antimicrobial activities. Protein glycation, one of the complications of diabetes, was inhibited by methanolic extract of finger millet. Finger millet phenolics can inhibit aldose reductase and snake venom phospholipases too. Among the cereals and millets, finger millet is the richest source of calcium (344 mg %) and potassium (408 mg %). Specifically, it is the richest source of Calcium among cereals with up to 10-fold higher Calcium content than brown rice, wheat or maize and three times than that of milk. It is also rich in iron and fiber, making this crop more nutritive as compared to other most commonly used cereals. Finger millet is enriched in the essential amino acids like lysine and methionine which are important in human health and growth but remain absent from most other plant foods. In addition, it also contains useful amounts of the two polyunsaturated fatty acids- linoleic acid and α -linolenic acid metabolized products of which facilitate normal development of the central nervous system. It also contains both water soluble and liposoluble vitamins: thiamin, riboflavin, niacin, and tocopherols. As finger millet is often grown and consumed primarily in developing countries by small-hold farmers with limited agronomic resources, it is often referred to as a "crop for the poor" or a "famine food". Despite the well-documented health benefits of finger millet, only a limited progress has been made in context to its nutraceutical applications as functional food. Although, it may have remained underutilized by the general population due to either unawareness or apprehension, its immense potential for enhancing the nutritional and therapeutic attributes by acting as functional food cannot be ignored.

ICT IN AGRICULTURE: A ROAD TO DOUBLING THE FARMERS' INCOME

***SHAHAMIR**

**Division of Agri. Extension & Communication, FOA Wadura, SKUAST-K*

Information and communication technology in agriculture (ICT in agriculture), also known as e-agriculture, is developing and applying innovative ways to use ICTs in the rural domain, with a primary focus on agriculture. ICT in agriculture offers a wide range of solutions to some agricultural challenges. It is seen as an emerging field focusing on the enhancement of agricultural and rural development through improved information and communication processes. In this context, ICT is used as an umbrella term encompassing all information and communication technologies including devices, networks, mobiles, services and applications; these range from innovative Internet-era technologies and sensors to other pre-existing aids such as fixed telephones, televisions, radios and satellites. E-agriculture continues to evolve in scope as new ICT applications continue to be harnessed in the agriculture sector. More specifically, e-agriculture involves the conceptualization, design, development, evaluation and application of innovative ways to use ICTs in the rural domain, with a primary focus on agriculture. Provisions of standards, norms, methodologies, and tools as well as development of individual and institutional capacities, and policy support are all key components of e-agriculture.

Keywords: e-agriculture, ICT, rural development, innovative and institutional capacity.

EFFECT OF BENZYLADENINE ON PHYSIOLOGICAL AND CHLOROPHYLL CHANGES OF ARTIFICIAL DROUGHT STRESS IN MAIZE SEEDLINGS.**SHAILESH AHIRE, PRANETI SONAWANE J. P. PATIL AND DR. PANKAJ SURYWANSHI***Department of Biochemistry and Molecular Biology, Anand Agricultural University, Anand-388110.*

Investigations were carried out at Department of Biochemistry, B. A. College of Agriculture, Anand Agricultural University, Anand to study the physiological and chlorophyll characterizations of two maize genotypes (resistant and susceptible) procured treatment given to seed followed by artificial drought (PEG) stress at 15 DAS. However, resistant genotype showed better performance in higher root-shoot length and weight than susceptible genotype under drought stress conditions, through treatment BA was higher root-shoot length and weight in resistant and susceptible genotypes. Biochemical analysis was carried out total chlorophyll content were increased in both the genotypes (resistant and susceptible) due to drought stress. Application of BA (25 ppm) could be increased in total Chlorophyll content and physiological parameters for improved biochemical content in both genotypes. Due to drought stress length and weight of root, shoot were decreased in maize seedlings of both the genotypes.

Key words: Physiological, Chlorophyll, PEG, Maize, *Zea mays L.*

NANOTECHNOLOGY IN SUSTAINABLE AGRICULTURE: AN INNOVATIVE APPROACH**SHAILJADHIMAN AND ARTI GOEL***Shailja Dhiman, Amity Institute of Microbial Biotechnology, Amity University, Noida, Uttar Pradesh, 201313, Amity Institute of Microbial Biotechnology, Amity University, Noida, Uttar Pradesh, 201313*

In the present scenario, among various technologies, nanotechnology has been considered as the most promising technology used in several sectors including agriculture. Agriculture is most important for providing food for humans and animals either directly or indirectly. As the world population is increasing day by day therefore, Agriculture, food, and natural resources are of main concern. Consequently, utilization of current technologies such as bio-nanotechnology is helpful for innovative future in the field of agriculture. The main motive behind using of biogenic nanoparticles as nanofertilizers in agriculture, is to lessen the use of harmful chemicals, minimize nutrient loss and increase yield through disease and nutrient management. Nanotechnology has the potential to improve the agriculture and food industry with novel nano tools for controlling disease caused by various pathogens and by providing nutrients to plants which are easy to absorb. The major interests of using nanotechnology in agriculture includes applications like bio-nano-fertilizers, nano-pesticides, nano-bactericides and nano-fungicides to increase the productivity without contamination of soils, water bodies and protection against several insect pests and microbial diseases. Hence, the present hypothesis will pave the way for the utilization of biogenic nanoparticles which are synthesized by microbes or plant extracts in enhancing agricultural yield because they have the potential to fertilize the soil by providing easily soluble nano nutrients as well as disease management by destroying the plant pathogens using nanoparticles in low doses without contaminating soil and water bodies with harmful chemicals.

STATUS AND CHALLENGES OF EXISTING TRANSFER OF TECHNOLOGY SYSTEM OF KRISHI VIGYAN KENDRA SHALINI PANDEY¹, NEHA GOSWAMI², RASHMI DURGAPAL³ AND DHRITI SOLANKI⁴*Department of Extension Education and Communication Management, Maharana Pratap University of Agriculture and Technology, Udaipur, Rajasthan.*

Krishi Vigyan Kendras (KVK) has been established by Indian Council of Agricultural Research (ICAR) as centre for transfer of technology at district level. In view of the changing scenario of agriculture, increasing urbanization, migration from rural to urban, declining involvement of youths in agriculture, inequality in distribution of incomes; there is a need to effective transfer of technologies from research system to grass root level. There is a dire need to ponder upon the existing transfer of technology model of KVK to address the newer challenges. Present review paper will put light on the status and methods used in transfer of agricultural technology by KVKs. The paper will also focus on the current challenges faced by KVKs network in transfer of technology. The paper will also highlight the possible course of action for strengthening the functioning of KVKs as per emerging needs.

Key words: Transfer of technology, KVK, extension system.

APPLICATION OF BIOINFORMATICS IN PLANT BREEDING**E. SHALINI PRIYA***S.V. Agricultural college, Tirupathi, ANGRAU*

The goal of plant genomics is to understand the genetic and molecular basis of all biological processes in plants that are relevant to the specie. This understanding is fundamental to allow efficient exploitation of plants as biological resources in the development of new cultivars with improved quality and reduced economic and environmental costs. This knowledge is also vital for the development of new plant diagnostic tools. Traits considered of primary interest are, pathogen and abiotic stress resistance, quality traits for plant, and

reproductive traits determining yield. A genome program can now be envisioned as a highly important tool for plant improvement. Such an approach to identify key genes and understand their function will result in a "quantum leap" in plant improvement. Additionally, the ability to examine gene expression will allow us to understand how plants respond to and interact with the physical environment and management practices. This information, in conjunction with appropriate technology, may provide predictive measures of plant health and quality and become part of future breeding decision management systems. Current genome programs generate a large amount of data that will require processing, storage and distribution to the multinational research community. The data include not only sequence information, but information on mutations, markers, maps, functional discoveries, etc. Key objectives for plant bioinformatics include: to encourage the submission of all sequence data into the public domain, through repositories, to provide rational annotation of genes, proteins and phenotypes, and to elaborate relationships both within the plants' data and between plants and other organisms.

THE 'FARMERS LAB', A TEMPLE OF LEARNING FOR THE FARMERS AND SUSTAINING SAFE AND COST EFFECTIVE REMEDIAL/ALTERNATIVE APPROACHES/STRATEGIES AGAINST CHEMICAL BASED FARMING

***SHALINI SINGH VISEN & NEETU SINGH**

**Amity Institute of Organic Agriculture, Amity Center for Biocontrol & Plant Diseases Management, Amity University, Sector 125, Noida, U.P., India*

'Farmers 'lab ' being the only source of knowledge bank for the helpless farmers as against the expensive and toxic farming, is expected to motivate the village farmers in gaining knowledge about the diagnostics of pests, diseases and other field related crop maladies faced by them and also their safe management by non-chemical and cost effective means. Training being imparted through illustrations, live materials and also microscopically including preparation of all the sustainable components of indigenous package and their sequential field application shall make them more confident in tackling their field problems. To maintain the sustainability of plant protection/production through latest technologies/packages and integrated farming among the motivated farmers who in turn inspire their fellow farmers Continuation of these indigenous, safe, cost effective packages for 3-4 cropping would lead towards complete organic farming thus improving the health of soil, crop and also the human beings. With the intension of sustaining the knowledge about the integrated farming and plant protection having been imparted to the growers/farmers through training and demonstrations at the hot spots in district Bulandshahar. It was felt desirable to establish the Farmers'lab a temple of learning for the farmers. This innovative idea came to the mind of proposers for the first time realizing the existence of such a unique platform under one umbrella of learning the basics of crop protection/production Science targeting mainly on safe and cost effective farming including their field application.

Key words: Farmers'lab , crop production, crop protection, integrated farming , IPM techno-packages

SCREENING OF RICE (*ORYZA SATIVA* L.) GENOTYPES FOR SUBMERGENCE TOLERANCE TRAITS AT SEEDLING STAGE

SHAMBHOO PRASAD, ASHISH KUMAR, VISHWAS MISHRA, BANDANA JAISWAL, REEN AND D. K. DWIVEDI

Department of Plant Molecular Biology and Genetic Engineering, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224229, U.P., India

A pot experiment was conducted with five rice genotypes Nagina 22, Swarna sub1, NDR 97, Susk Samrat and NDR 9830102 to evaluate submergence tolerance traits at vegetative stage. Thirty five days old seedling was exposed to 11 days complete submergence. At the end submergence, shoot elongation, catalase activity, chlorophyll content and total soluble sugar were measured against control. Less shoot elongation, high catalase activity and less percent reduction in chlorophyll content and total soluble sugar were recorded in Swarna sub 1 and NDR 9830102. Nagina 22 failed to survive after desubmergence. Survival percentage of Swarna sub1, NDR 9830102, NDR 97 and Susk Samrat was nearly 95, 75, 10 and 8 percent respectively. The days to 50% flowering and maturity were less effected in Swarna sub1 and NDR 9830102 and comparison to other genotypes. The high survival percentage in Swarna sub1 and NDR 9830102 was due to reserved carbohydrates, less shoot elongation and high activity of anti oxidant enzymes and consequently these two genotypes also showed less reduction in yield and yield components.

ADOPTION OF IMPROVED GUAVA (*PSIDIUM GUAJAV* L.) CULTIVATION PRACTICES AMONG ORCHARDISTS

SHANKAR DAYAL BHARTI*, DHEERENDRA KUMAR**

Department of Agriculture Extension and Communication, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut-250110 (U.P)

Guava (*Psidium guajava* L.) is the most important and commercially cultivated fruit crop belongs to the family Myrtaceae. The fruit is very delicate in the flavor and rich source of vitamin C, B2, B1, pectin and minerals like Calcium, Phosphorus and Iron. Hence known as 'Poor man's apple' and 'Apple of tropics'. The present study was undertaken in the Department of Agriculture Extension, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut (U.P). Adoption of improved practices for guava by the farmers and

constraints faced by them were studied in Baghara and Charthawal block of Muzaffarnagar district of Uttar Pradesh. The major constraints were broadly classified as economical, infrastructural, agro-climatic and technological aspects. About 50 to 80% of the farmers responded in adoption of recommended package of practices like selection of suitable cultivar, spacing and timely inter-cultivation, while the reverse is true in adoption of use of manures and recommended fertilizers, application of protective irrigation and timely need based plant protection measures. Lack of awareness, non-availability of genuine planting material, inputs like FYM, vermicompost, biofertilizers, micronutrients, non availability of labours at time, damage by pests like mealy bug, T-mosquito bug and fruit fly, diseases like dieback, fruit rot, fruit canker and leaf bronzing, marketing facility, and lack of awareness of bahar treatment were some of the other major constraints reported by the farmers.

INDIGENOUS TECHNICAL KNOWLEDGE (ITK) AND THEIR ROLE IN SUSTAINABLE GRASSROOTS INNOVATIONS: AN ILLUSTRATION IN INDIAN CONTEXT

SHANKAR LALSUNDA¹, R. K. JHAKAR², H. P. PAREWA³

Department of Soil Science, College of Agriculture, S.K. Rajasthan Agricultural University, Bikaner.

Indigenous Technical Knowledge (ITK) has immense potential for innovation, especially at the grassroots level. India is a country populated by a number of indigenous communities, most of which have their own set of unique traditional knowledge and technology base. Many of these knowledge and technologies are at par with the modern knowledge and technology system and have been provided the indigenous communities with comfort and self-sufficiency. These traditional knowledge and technologies have played a significant role in the overall socio-economic development of the communities. A study on some of the aboriginal knowledge and technologies, with special reference to the concept of Indigenous Technical Knowledge (ITK), prevalent among a number of indigenous communities was carried out and the significance of the same in innovation has been evaluated. The study was conducted within the framework of "sectoral system of innovation". A wide range of diverse sectors including agriculture, animal husbandry, fishing and textile were considered for the purpose of the study as all these sectors are imperative in Indian context. During the course of the study, it has been observed that there is an instant need to document and preserve the Indigenous Technical Knowledge (ITK) of different communities, many of which are at the brink of extinction. There is a lack of proper alliance between the practice of indigenous and modern knowledge. There are serious issues related to intellectual property rights. An appropriate association between the traditional and modern knowledge and technology systems has immense potential to benefit the society.

Keywords : Sectorial system, Innovation, Intellectual property rights

RECENT DEVELOPMENT IN BIOFERTILIZERS IN TEMPERATE FRUIT PRODUCTION

'SHARBAT HUSSAIN*, 'RIFAT BHAT, 'SHEERAZA. WANI, 'RAHILASHAMEEMAND 'MOHIT HUSAIN

¹Division of Fruit Sciences, ²Faculty of Forestry, Sher-e-Kashmir University of Agricultural Sciences and Technology of Kashmir Shalimar, Srinagar, Jammu and Kashmir-190025.

India having 2.27 per cent of the total land area, feeds more than 16 per cent of world population. Such a huge population magnifies the demand for more food from shrinking cultivated area which requires huge amount of fertilizers and other inputs. The chemical fertilizers have played a very significant role in intensive food production, which has brought many fold increase in production, but large scale use of chemical fertilizers causes problem of ground water and environmental pollution through leaching, volatilization, denitrification and wastage of nutrients. Indiscriminate use of chemicals contributed in loss of soil biological dynamism and productivity along with addition of salts to the soil. Biofertilizers or microbial inoculants are carrier based ready to use live bacterial or fungal formulations, which on application to plants, soil or composting pits, help in mobilization of various nutrients by their biological activity and plays a very significant role in improving soil fertility by fixing atmospheric nitrogen both in association with plant roots and without it, producing numerous plant growth regulators, protecting plants from phytopathogens by controlling or inhibiting them, improving soil structure and bio remediating the polluted soils by sequestering toxic heavy metal species also, they are environmental friendly playing a significant role in crop production. Nitrogen fixing bacteria and phosphate solubilizer are the main biofertilizers for horticultural crops. Use of FYM + Bio + Mg increased the yield and fruit quality of pear. Conjoint use of biofertilizers with inorganic manure achieved the highest berry yield, improved the quality of strawberry and also sustains the fertility of soil. Beneficial effect of bioorganic nutrient sources on growth, fruit yield and biochemical attributes of kiwi fruit has been reported. Maximum fruit set, minimum fruit drop and highest fruit yield was recorded with the application of FYM 30kg + Vermicompost 10kg + poultry manure 2.5kg + neem cake 3kg/tree in peach. The integration of inorganic fertilizer with organic manures and biofertilizers can achieve the highest fruit yield with improved fruit quality and soil fertility status of apple.

Key words: Biofertilizers, phytopathogens, Nitrogen fixation, manure and soil fertility.

ROLE OF BIOLOGICAL CONTROL IN ORGANIC FARMING

SHASHANK MISHRA*, PRASHANT MISHRA, RAVIKANT SINGH, JASKARAN SINGH AND RANVIJAY SINGH*Department of Plant Pathology, Sardar Vallabhbhai Patel University of Agriculture and Technology, Meerut, 250110 India*

At the present time due to use of heavier doses of chemical fertilizers for crop nutrition and pesticides for pest management by farmers, there are many diseases e.g. cancer, allergic problems and respiratory dysfunctions in people due to pollutions and food contamination by different chemical application which is very harmful to animals and environment. Organic agriculture can be defined as farming systems where the use of pesticides, herbicides and chemical fertilizers is prohibited. These systems rely on crop rotations, natural nitrogen fixation, biologically active soil, recycled farm manure, crop residues and biological or mechanical weed and pest control. Major benefits to consumers of organic food are better health through increased nutritional quality and reduced pesticide exposure for all health harming chemicals such as pesticides, fungicides and herbicides. Due to less or no use of pesticides, the pest management is a big problem in organic farming system. For manage the pests in organic farming system IPM is applied as the potent disease management programme, IPM includes the different methods e.g. physical, mechanical, cultural, legal, biological, biotechnological and chemical methods for pest management. Biological control of pests is an ecofriendly method which uses natural or modified organisms, and genes or gene products of selected organisms to reduce inoculum density or disease producing activity of a pathogen or undesirable pests affecting crops. There are three basic types of biological pest control strategies: importation, augmentation and conservation. Natural enemies of insect pests, also known as biological control agents, include predators, parasitoids and pathogens. Biological control agents of plant diseases are most often referred to as antagonists. Biological control agents of weeds include seed predators, herbivores and plant pathogens. Bio-pesticides are certain types of pesticides derived from natural material such as animals, plants, bacteria and certain minerals which are less toxic to human, biodiversity and pose a lower risk than conventional pesticides, great advantage of microbial pesticides is the specificity of their toxic action and their safety to nontarget organisms. These products cause minimal environmental disruption.

PERFORMANCE OF SUPER ABSORBENT POLYMER (HYDROGEL) ON WATER PRODUCTIVITY AND YIELD OF WINTER MAIZE (ZEA MAYS L.)**SHASHANK TYAGI, ROHIT KUMAR AND S.K. PATHAK***Department of Agronomy, Bihar Agricultural University, Sabour, Bhagalpur- 813210, India*

A field experiment was carried out during *rabi* 2011-12 at Bihar Agricultural College farm, Sabour to study the effect of hydrogels on yield attributes, yield of maize and water productivity. The design of the experiment was split plot design replicated thrice and the treatments comprised of main plot treatment having two sources of hydrogel i.e. Stockosorb and Pusa gel and six doses of hydrogel i.e. control, 50, 75, 100, 125 and 150% hydrogel dose were tested in sub-plots. Application of 150% gel dose recorded highest grain yield which was significantly higher over rest of the treatments. Highest grain yield (81.5 q ha⁻¹) was recorded under 150% dose of hydrogel which was 2.9% higher than those of 125% dose of hydrogel, respectively. However, application of 100 and 125% dose of hydrogel achieved similar grain yields. Recommended dose of hydrogel recorded 2.8, 11.1 and 19.1% higher yield over 75%, 50% gel dose and control. Highest yield attributes were in 150% gel dose being at par with 125 and 100% gel dose and significantly more over control, 50 and 75% dose. Recommended hydrogel dose improved water use efficiency over 50% gel dose and control. Hydrogel sources were non-significant for it; however, stockosorb was relatively much effective. Among hydrogel doses, 150% dose was registered for maximum water use efficiency being at par with 100 and 125% dose. It may be concluded that hydrogel sources did not have significant effect on maize yield, however, gel doses could make some significant impact on maize with increasing gel doses up to 150% in terms of enhancement in yield of maize and water use efficiency.

DOUBLING FARMERS INCOME THROUGH INNOVATIVE APPROACH**SHASHIKANT GOYAL, B. JIRLI, SHANI KUMAR SINGH***Department of Extension Education, I. Ag. Sc., BHU, Varanasi-221005*

India is a country where agriculture is the main occupation of the people According to 2011 Agricultural Census of India, an estimated 61.5% of the 1300 million Indian population is rural and dependent on agriculture. The base income of the farmers was Rs. 77,976 in 2012-13 as per the NSSO 70th Round data. The Effort of government is through increasing Minimum Support Price of cereals and Direct Benefit Transfer, Reduction in input cost. Policies reforms involved liberalization, Deregulation and removal of excessive control and restriction on private sector. Removal of licensing requirements and stock limits on foodstuff order. Ways for Doubling Farmers Income to improvement in productivity and resource use efficiency, increase in cropping intensity and diversification towards high value crop, shifting cultivators to non-farm and subsidiary activities. Strategies are to development of initiatives including infrastructure (schemes and programs), Technology and Institutional mechanism. Crop productivity requires growth for doubling income is 4.1% and livestock value added by 6.0% per year, it can enhance through technology generation and dissemination. Various initiative required to active and coordinated participation of various ministries of central government and states, While lead role played by ministry of agriculture co-

TO STUDY ABOUT WAYS TO DOUBLE THE INCOME OF FARMERS OF INDIA

SHASYENDRA YADAV

College of Agriculture Sciences, Teerthanker Mahaveer University, Moradabad.

Hypothesis: Farmers of India need to be educated to not throw away the agricultural wastes but to make money by recycling it into something valuable that holds the power to generate considerable income. Method: Herein this research, I have taken model based approach. I believe that India must incorporate little of each nation in order to achieve it's own agricultural success. Result: A lot can be done to educate the farmers of India and increase or double their income in upcoming years. They need to be educated and familiarized with the micro-irrigation techniques, tailor made for their region in joint collaboration with R&D departments of MNCs in the irrigation sector like Jains etc. The agricultural wastes which are usually burnt down can also be converted into useful resource which in turn leads to income generation for the farmer. In such cases, it will also lead to less environmental pollution as these "wastes" won't be burnt down anymore. The reduction of post-harvest food losses, which are particularly high in perishable crops in developing countries, is important not only from an obligation to avoid waste, but also because the cost of preventing food losses in general is considered to be less than producing a similar additional amount of food of the same quality. In perishable vegetatively propagated crops like the potato, appropriate post-harvest technology is not only required to reduce food losses, but also to maintain the perishable planting material from one growing season to the next.

EFFECT OF PLANT GROWTH REGULATORS TO ENHANCE QUALITY AND YIELD OF VEGETABLES

SHAUNAK SINGH, NAVNEET SINGH, RAVI PRATAP SINGH

Department Of Vegetable Science, N. D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.)

The use of plant growth regulators (PGRs) in modern horticulture is well established. Indeed certain fields of horticulture such as asexual propagation are heavily dependent on the use of synthetic growth regulators. During recent years, the interest in vegetable production has increased rapidly because of good price value and place of vegetables in national food requirement. Besides, growth regulating chemicals are also becoming important in the field of horticulture for the modification of vegetative growth, flowering, fruiting and quality. Plant growth regulators in vegetables provides professionals and researchers with the information needed to effectively tap these versatile resources to enhance vegetables production. Plant growth regulators have found specific niches in the production of commercial vegetables but many opportunities continue to exist for improving quality, efficiency and coordination in commercial production. Auxin produced seedless fruits in cucumbers and watermelon, PCPA (50-100) ppm induced parthenocarp in tomato and brinjal. Naphthyl acetic acid (NAA) does not occur naturally. NAA (100 ppm) treatment induces parthenocarp of fruits in tomatoes, ladies finger and brinjal. Ethylene is the only gaseous hydrocarbon hormones which plays an important role in the ripening of fruits, inhibition of root growth, abscission and other growth processes. Ethrel treatment has been found to change sex expression in cucurbits. In cucurbits, GA₃ sprays have been made to induce staminate flowers in gynoeccious lines. Silver nitrate at 500 mg/L has been reported to be as effective as GA₃ in inducing male flowers on gynoeccious lines of cucumber. Maleic hydrazide (MH) functions as a growth regulator acting especially on root vegetables. Maleic hydrazide is applied as over-the-top foliar spray when the foliage is still in a good condition. Application of MH (2500 ppm) 15 days before harvesting prevents sprouting of onion in storage. Routinely, it is also used as a sprouting inhibitor during storage. These hormones are not known to be harmful to humans, but when applied outside of those guidelines, they can cause problems with excessively fast growth, including external fruit ripening prior to interior ripening, and residual PGRs remaining in plants and fruits after application.

Key words: Plant growth regulators, Ethrel, NAA, cucurbits. Tomamto, brinjal, onion.

APPLICATION OF SILICON ON CROP PRODUCTION

SHEILENDRA KUMAR, KISHORE KUMAR DAS, PRAMOD KUMAR, SURENDER KUMAR, PRADEEP KUMAR

College of Agriculture, Bikaner- 334006, Rajasthan

Among the plants, silicon concentration is found to be higher in monocotyledons than in dicotyledons and its level increased from legumes < fruit crops < vegetables < grasses < grain crops. The role of silicon in plant biology is to reduce multiple stresses including biotic and abiotic stresses. It is also known to increase drought tolerance in plants by maintaining plant water balance, photosynthetic activity, erectness of leaves and structure of xylem vessels under high transpiration rates. Silicon application improved water economy and dry matter yield. It enhanced the leaf water potential under water stress conditions, reduced the incidence of micronutrient and metal toxicity. The presence of Silicon also been reported to affect the absorption and translocation of several macro and micronutrients. Si is

accumulated in plants to total concentrations in dry matter similar to those of essential macro-nutrients such as Potassium, Calcium, Magnesium, Sulphur and Phosphorous (Epstein, 1999). More recently, silicon amendments were shown to reduce the leaching of phosphate, nitrate and potassium.

GENETIC DIVERSITY OF INDIAN COMMON BEAN GERMPLASM COLLECTIONS BASED ON MICROSATELLITE MARKERS

SHAILJASHARMA* AND SANCHIT THAKUR

Department of Crop Improvement, CSKHPKV, Palampur, Himachal Pradesh-176062, India

Common bean (*Phaseolus vulgaris* L.), locally known as rajmash, belongs to family *Leguminosae* and subfamily *Papilionaceae*. Success of crop breeding depends on the isolation of genetically superior genotypes based on the amount of variability present in the materials. Therefore, evaluation of the genetic diversity present in Indian accessions of common beans is essential for conservation, management and utilization of these genetic resources. Genetic diversity of one hundred sixty five common bean (*Phaseolus vulgaris* L.) accessions of north west Himalayan origin with 4 checks was studied using Simple Sequence Repeat (SSR) markers. 20 out of 55 primers screened showed polymorphism across present set of genotypes. A total of 124 amplicons were scored using these 20 primers indicating fair amount of variation at the DNA level among these accessions. Cluster analysis delineated the genotypes into four groups. The common bean seed size includes large, medium and small seeded out of which large seeded genotypes are mostly placed in Andean gene pool along with medium seed size, whereas Mesoamerican gene pool accommodates small seeded genotype.

Keywords: Common bean, Morphological diversity, SSR markers, Andean and Mesoamerican gene pools, Genetic divergence

HIGH TEMPERATURE STRESS ON CHICKPEA

SHENDE R. T.¹, ARUN KUMAR¹, ROSHAN SHINDE² AND R. S. SENGAR¹

¹Sardar vallabh bhai patel University of Agriculture and Technology, Meerut, UP; , ²Indira Gandhi Agriculture University, Raipur, India;

Chickpea play a significant role in food and nutritional security in cool regions. Heat or high temperature stress is common in major chickpea-growing areas in the world. Chickpea is sensitive to high temperatures, especially in the reproductive phase. Heat stress is the major (abiotic stress) environmental factors reducing productivity of food grain crop and pulses. The impact of heat stress on important pulse crops (cool season pulse chickpea) will be reviewed. The impact of heat stress of chickpea depends on duration time and intensity of stress. In general, heat stress has negative effects on production, especially during gamete development, podding and flowering. Yield reductions have been observed at a temperature of 30°C at 50% flowering and >30°C for 34 days at 100% flowering time that such conditions reduced the duration of flowering and pod filling, resulting in large yield losses. Heat caused withering, burning of lower leaves, desiccation of poorly developed plants, stunting flower and pod abortion, and reduced root nodulation, nitrogen (N) fixation and seed yield. The optimal temperature for germination of chickpea pollen is 25°C with drastic reductions at cooler and warmer temperatures. Flowers are the most sensitive organs to heat. There is a need to develop high throughput phenotyping techniques and/or physiological, biochemical or molecular markers that determines reproductive function. Future research should focus on screening germplasm collections to check genetic variability and identify the heat tolerant genotypes for use in breeding programs.

EFFECT OF PLANT GROWTH REGULATORS ON GROWTH PARAMETERS, BIOCHEMICAL STUDIES AND YIELD OF MUSTARD

SHIKHASHAHI

Department of Crop Physiology, N.D.U.A&T. Kumarganj, Faizabad

The Indian mustard (*Brassica juncea* L.) is an important oilseed crop, its botanical name is *Brassica juncea* L. (2n=18) and belongs to family Cruciferae. In India, it is the second most important edible oilseed crop after groundnut sharing 25-30%. The share of oilseeds is 14.1% out of the total cropped area, in India, rapeseed mustard accounts for 3% of it. Mustard seed is the second largest produced oilseed in the world. India contributes 28.3% and 19.8% in world acreage and production. GA₃ enhances growth activities to plant, stimulates stem elongation and increases dry weight and yield. Salicylic acid (SA) is a naturally occurring signalling molecule and growth regulator that enhances plant growth particularly in stress conditions. Abiotic stresses (such as metals/metalloids, salinity, extreme temperatures, and drought) are among the most challenging threats to agricultural system and economic yield of crop plants & they are controlled by Salicylic acid. Various concentrations of GA₃ (50ppm, 100ppm, & 150ppm) & Salicylic acid (100ppm, 200ppm, 300ppm) were taken along with untreated control. PGRs were applied on 30 DAS. Observations were recorded at 40, 60, 80 days & at maturity and growth parameters like plant height, number of primary & secondary branches plant⁻¹, total dry biomass plant⁻¹, biochemical parameters like chlorophyll content & catalase activities in green leaves. Foliar application of different concentrations of GA₃ and Salicylic Acid influenced on all characters of mustard crop.

VACUUM FRYING: A NEW TECHNOLOGY FOR HEALTHY FRIED PRODUCTS**SHIKHANGI SINGH¹, P.K. OMRE²***Department of Post-Harvest Process and Food Engineering, G.B. Pant University of Agriculture & Technology, Pantnagar 263145, India*

Vacuum frying is a novel technique which uses pressure below the atmospheric pressure (~8KPa) and temperature below 80°C, thereby preserving the natural quality attributes of fried products. Vacuum frying is the method of limiting the oil uptake in fried products, maintaining the natural color and flavor. The vacuum frying temperature is done much lower than boiling point of water i.e. 100°C. Hence, there is no burning of texture and the carcinogen acrylamide formation is reduced up to 97%. This technique is gaining more demand due to recent researches in the relationship between atmospheric fried food and their diverse effect on consumption on human health. Due to the high initial moisture content of the fruits, the frying process takes longer time. Therefore, before vacuum frying process pre-treatments are applied i.e. blanching, pre-drying, osmotic dehydration, freezing, hydrocolloids and anti-browning agent. Pre-treatments are necessary in moisture removal kinetics, product yield, and final product moisture content, oil uptake by the product and oil absorption rate in the final product. Centrifugation is done as a post treatment of vacuum frying process for removing the surface oil and can be part of the frying equipment. Centrifugation done at higher rpm and low pressure significantly decrease the amount of surface oil that can penetrate the porous products when breaking the vacuum and hence reduce the oil uptake up to 64%. In future, the vacuum fried products would be a suitable alternate for conventional fried products with better nutritional and sensorial properties.
